Sue Peters, PT, PhD
Ricardo Viana, OT, MD
Sean Dukelow MD
Tom Miller, MD
Robert Teasell, MD

Welcome to the 21st Edition of the EBRSR!

The EBRSR was initiated in 2001 with funding from the Heart and Stroke Foundation of Canada. The first edition was published in 2002. It is now in its 21st edition. The Lower Extremity Motor Rehabilitation Interventions is chapter 9 and the largest chapter in the EBRSR. It alone has data on 1,548 RCTs published in English journals up to the end of 2024. Special thanks to Ben Luebke, Sarvenaz Mehrabi, Mohammad R. Safaei-Qomi, and Cecilia Flores-Sandoval for their work on updating this chapter. We are working on the next update.

Robert Teasell MD FRCPC

This work was funded by the Heart and Stroke Foundation of Canada, the St. Joseph's Health Care (London) Foundation, the Academic Medical Organization of Southwestern Ontario (AMOSO) (Innovation Fund Project #INN25-014), and the CanStroke Recovery Trials Platform. The CanStroke Platform acknowledges financial support of the Canada Brain Research Fund (CBRF), an innovative arrangement between the Government of Canada (through Health Canada) and Brain Canada Foundation, the Governors of the University of Calgary, Heart & Stroke Foundation Canadian Partnership for Stroke Recovery and Sunnybrook Research Institute in Toronto.

Contents

Title Page and Authors 1
Welcome to the 21st Edition of the EBRSR (funding; how to cite this chapter) 2
Chapter Structure and Format 3
- Interpretation of Results (Direction of Effect) 3
- Key Points Summary – effect symbols (+, −, =) 3

Modified Sackett Scale (Levels of Evidence) 4
PICO Conclusion Statements (colour coding of statements) 5
Outcome Measures (ICF categorization) 6
1. Body Functions and Structures 7
- 1.1 Motor Recovery 7
- 1.2 Biomechanical Gait Measures 7
- 1.3 Biomechanical Balance Measures 8
- 1.4 Muscle Strength 8
- 1.5 Spasticity 9
- 1.6 Range of Motion 9
- 1.7 Neurophysiological Measures 10
- 1.8 Aerobic Measures 10
- 1.9 Sensory/Proprioception 11
- 1.10 Pain 11

2. Activities 11
- 2.1 Activities of Daily Living 11
- 2.2 Gait Speed 12
- 2.3 Gait Endurance 12
- 2.4 Functional Mobility 12
- 2.5 Balance 14
- 2.6 Falls and Fear of Falls 14

3. Participation 15
- 3.1 Quality of Life 15

Other Associated Outcome Measures 16
- A. Mood 16
- B. Fatigue and Sleep 16
- C. Cognition 16
- D. Upper Extremity 17

Index of Data Tables

Intervention category, RCT count, number of new RCTs, subcategory count, starting page, and page span are based on the original Chapter 9 Index of Data Tables (printed pages 18–19). Page spans are calculated from the next listed starting page.

Table	Intervention category	RCTs (new)	Subcategories	Starts	Pages
1	Neurodevelopmental Techniques and Motor Relearning	18 (5)	9	20	20–44
2	Sit-to-Stand Training	15 (1)	11	45	45–53
3	Wheelchair Use	2 (0)	2	54	54–55
4	Trunk Training	49 (13)	13	56	56–85
5	Task-Specific Training	48 (5)	23	86	86–123
6	Constraint-Induced Movement Therapy (CIMT)	9 (2)	5	124	124–131
7	Non-Technological Overground Walking and Gait Training	40 (11)	16	132	132–164
8	Cycle Ergometer Training	28 (4)	14	165	165–194
9	Treadmill Training	106 (13)	39	195	195–291
10	Physiotherapy and Exercise Programs	84 (20)	32	292	292–331

11	Balance Training	94 (23)	36	332	332–395
12	Stretching or Mobilization Exercises	53 (22)	23	396	396–439
13	Orthotic Devices	82 (18)	25	440	440–489
14	Hippotherapy	8 (3)	5	490	490–496
15	Biofeedback	67 (11)	22	497	497–547
16	Dual-Task Training	28 (4)	12	548	548–562
17	Mental Practice	27 (5)	15	563	563–577
18	Action Observation	14 (0)	7	578	578–584
19	Mirror Therapy	26 (4)	10	585	585–603
20	Aquatic Therapy	29 (4)	8	604	604–618
21	Strength and Resistance Training	53 (7)	13	619	619–660
22	Rhythmic Auditory Stimulation	27 (5)	9	661	661–675
23	Respiratory Training and Devices	10 (3)	5	676	676–683
24	Home-Based and Caregiver-Mediated Exercise Programs	45 (7)	9	684	684–706
25	Telerehabilitation and Technology-Based Home Exercise Programs	24 (8)	6	707	707–719
26	Virtual Reality	86 (17)	12	720	720–768
27	Electromechanical and Robotic Devices	127 (34)	33	769	769–854
28	Functional Electrical Stimulation	73 (12)	23	855	855–901
29	Neuromuscular Electrical Stimulation (NMES)	22 (5)	16	902	902–925
30	Transcutaneous Electrical Nerve Stimulation (TENS)	21 (0)	10	926	926–946
31	Muscle Vibration	36 (5)	9	947	947–965
32	Additional Afferent and Peripheral Stimulation Methods	11 (6)	9	966	966–973
33	Remote Ischemic Conditioning	2 (0)	1	974	974–975
34	Thermal Stimulation and Cryotherapy	9 (1)	4	976	976–981
35	Extracorporeal Shockwave Therapy and Therapeutic Ultrasound	14 (5)	8	982	982–990
36	Repetitive Peripheral Magnetic Stimulation	3 (1)	2	991	991–994
37	Repetitive Transcranial Magnetic Stimulation (rTMS)	33 (8)	12	995	995–1015
38	Theta Burst Stimulation (TBS)	8 (3)	4	1016	1016–1023
39	Transcranial Direct Current Stimulation (tDCS)	57 (21)	20	1024	1024–1078
40	Antidepressants	8 (0)	5	1079	1079–1084
41	Secondary Prevention Medications	7 (1)	7	1085	1085–1088
42	Edaravone	2 (0)	2	1089	1089–1091
43	Stimulants	10 (0)	4	1092	1092–1095
44	Dopamine Agonists	6 (0)	3	1096	1096–1100
45	Nerve Block Agents	4 (0)	4	1101	1101–1104
46	Botulinum Toxin	46 (6)	17	1105	1105–1130
47	Antispastic Drugs	9 (1)	6	1131	1131–1135
48	Cerebrolysin	1 (0)	0	1136	1136–1137
49	4-Aminopyridine	2 (0)	1	1138	1138–1139
50	Biologics and Targeted Molecular Therapies	7 (1)	5	1140	1140–1143
51	Anabolic Steroids	1 (0)	0	1144	1144–1145
52	Supplements and Vitamins	8 (2)	4	1146	1146–1156
53	Acupuncture and Massage	51 (9)	13	1157	1157–1187
54	Electroacupuncture and Transcutaneous Electrical Acupoint Stimulation	8 (1)	4	1188	1188–1193
55	Traditional Herbal Medicines	8 (1)	4	1194	1194–1199

Appendix A: Key Points – Detailed Contents

Appendix A begins on printed page 1200 and compiles the Key Points from all 55 intervention categories. Subsection page references below identify the page on which each heading first appears.

A.1 Neurodevelopmental Techniques and Motor Relearning (Table 1)....1200
A.2 Sit-to-Stand Training (Table 2)....1202
A.3 Wheelchair Use (Table 3)....1202
A.4 Trunk Training (Table 4)....1203
A.5 Task-Specific Training (Table 5)....1205
A.6 Constraint-Induced Movement Therapy (CIMT) (Table 6)....1208
A.7 Non-Technological Overground Walking and Gait Training (Table 7)....1208
A.8 Cycle Ergometer Training (Table 8)....1211
A.9 Treadmill Training (Table 9)....1213
A.10 Physiotherapy and Exercise Programs (Table 10)....1220
A.11 Balance Training (Table 11)....1223
A.12 Stretching or Mobilization Exercises (Table 12)....1228
A.13 Orthotic Devices (Table 13)....1231
A.14 Hippotherapy (Table 14)....1235
A.15 Biofeedback (Table 15)....1236
A.16 Dual-Task Training (Table 16)....1240
A.17 Mental Practice (Table 17)....1241
A.18 Action Observation (Table 18)....1242
A.19 Mirror Therapy (Table 19)....1242
A.20 Aquatic Therapy (Table 20)....1244
A.21 Strength and Resistance Training (Table 21)....1245
A.22 Rhythmic Auditory Stimulation (Table 22)....1248
A.23 Respiratory Training and Devices (Table 23)....1249
A.24 Home-Based and Caregiver-Mediated Exercise Programs (Table 24)....1249
A.25 Telerehabilitation and Technology-Based Home Exercise Programs (Table 25)....1251
A.26 Virtual Reality (Table 26)....1251
A.27 Electromechanical and Robotic Devices (Table 27)....1254
A.28 Functional Electrical Stimulation (Table 28)....1260
A.29 Neuromuscular Electrical Stimulation (NMES) (Table 29)....1263
A.30 Transcutaneous Electrical Nerve Stimulation (TENS) (Table 30)....1266
A.31 Muscle Vibration (Table 31)....1268
A.32 Additional Afferent and Peripheral Stimulation Methods (Table 32)....1269
A.33 Remote Ischemic Conditioning (Table 33)....1269
A.34 Thermal Stimulation and Cryotherapy (Table 34)....1269
A.35 Extracorporeal Shockwave Therapy and Therapeutic Ultrasound (Table 35)....1270
A.36 Repetitive Peripheral Magnetic Stimulation (Table 36)....1270
A.37 Repetitive Transcranial Magnetic Stimulation (rTMS) (Table 37)....1271
A.38 Theta Burst Stimulation (TBS) (Table 38)....1272
A.39 Transcranial Direct Current Stimulation (tDCS) (Table 39)....1273
A.40 Antidepressants (Table 40)....1277
A.41 Secondary Prevention Medications (Table 41)....1278
A.42 Edaravone (Table 42)....1278
A.43 Stimulants (Table 43)....1278
A.44 Dopamine Agonists (Table 44)....1279
A.45 Nerve Block Agents (Table 45)....1279
A.46 Botulinum Toxin (Table 46)....1279
A.47 Antispastic Drugs (Table 47)....1282
A.48 Cerebrolysin (Table 48)....1282
A.49 4-Aminopyridine (Table 49)....1282
A.50 Biologics and Targeted Molecular Therapies (Table 50)....1282
A.51 Anabolic Steroids (Table 51)....1283
A.52 Supplements and Vitamins (Table 52)....1283
A.53 Acupuncture and Massage (Table 53)....1283
A.54 Electroacupuncture and Transcutaneous Electrical Acupoint Stimulation (Table 54)....1285
A.55 Traditional Herbal Medicines (Table 55)....1286

Source and pagination notes

- Primary source: Luebke, B., Mehrabi, S., Safaei-Qomi, M. R., Flores-Sandoval, C., Gelinas, B., Hassan, A., Chow, M., Chowdhury, J., Iruthayarajah, J., Payne, M. W., Peters, S., Viana, R., Dukelow, S., Miller, T., & Teasell, R. (2026). Chapter 9: Lower Extremity Motor Rehabilitation Interventions. In Evidence-Based Review of Stroke Rehabilitation (21st Edition).
- The original Index of Data Tables lists 55 intervention categories. Page-span end points are calculated as the page before the next category begins. Table 55 is shown through page 1199, immediately before Appendix A.

- Contents headings, intervention counts, and appendix subsection page references are transcribed from the supplied Chapter 9 PDF. The index does not revise or reinterpret the chapter's evidence or conclusions.

Chapter Structure and Format

Each intervention is described in a table that includes the following:

Intervention vs Control		
Author (Year) PEDro Score Sample Size (Start) Sample Size (End) Time Post Stroke Study Design	E: Intervention C: Control Duration (Session length, frequency per week, number of weeks)	Outcome Measure Result (Direction of effect)

Interpretation of Results (Direction of Effect)

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

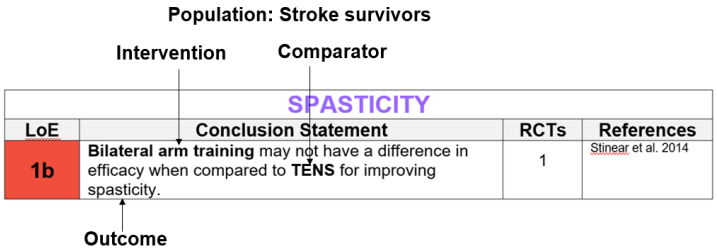
- indicates no statistically significant between groups differences at α=0.05

no stats/no between-group stat indicates the study did not report a between groups comparison for that outcome

Key Points Summary

Effect	Interpretation
+	**Favourable**
–	**Not Favourable**
=	**Mixed Evidence**

Modified Sackett Scale



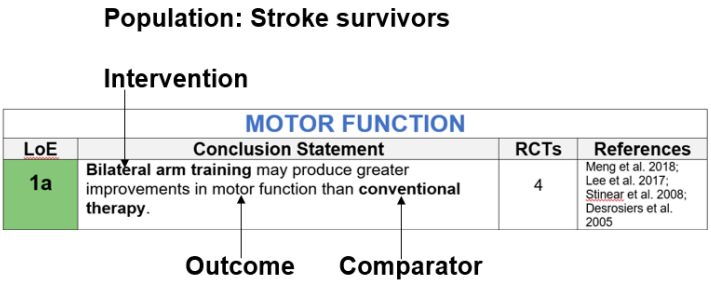
The Modified Sackett Scale was used to determine the level of evidence for each conclusion statement.

Level of evidence	Study design	Description
Level 1a	Randomized controlled trial (RCT)	More than 1 higher quality RCT (PEDro score ≥6).
Level 1b	RCT	1 higher quality RCT (PEDro score ≥6).
Level 2	RCT	Lower quality RCT (PEDro score <6).
	Prospective controlled trial (PCT)	PCT (not randomized).
	Cohort	Prospective longitudinal study using at least 2 similar groups with one exposed to a particular condition.
Level 3	Case Control	A retrospective study comparing conditions, including historical cohorts.
Level 4	Pre-Post	A prospective trial with a baseline measure, intervention, and a post-test using a single group of subjects.
	Post-test	A prospective post-test with two or more groups (intervention followed by post-test and no re-test or baseline measurement) using a single group of subjects
	Case Series	A retrospective study usually collecting variables from a chart review.
Level 5	Observational	Study using cross-sectional analysis to interpret relations. Expert opinion without explicit critical appraisal, or based on physiology, biomechanics or "first principles".
	Case Report	Pre-post or case series involving one subject.

PICO Conclusion Statements

Chapter 9: Lower extremity motor rehabilitation interventions synthesizes study results from only randomized controlled trials (RCTs), all levels of evidence (LoE) and conclusion statements are presented in the Population Intervention Comparator Outcome (PICO) format.

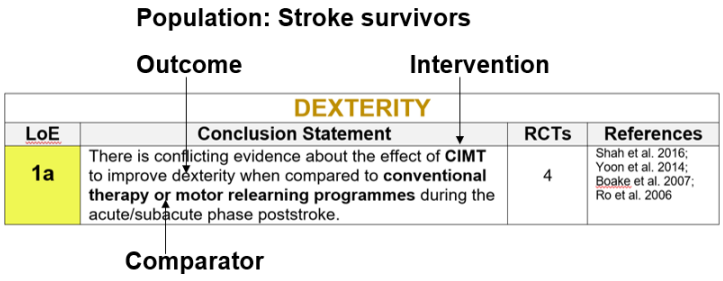
For example:



SPASTICITY			
LoE	Conclusion Statement	RCTs	References
1b	**Bilateral arm training** may not have a difference in efficacy when compared to **TENS** for improving spasticity.	1	Stinear et al. 2014

Red statements like above, indicate that the majority of study results when grouped together show no significant differences between intervention and comparator groups.

Green statements indicate that the majority of study results when grouped together show a significant between group difference in favour of the intervention group.



For example:

MOTOR FUNCTION			
LoE	Conclusion Statement	RCTs	References
1a	**Bilateral arm training** may produce greater improvements in motor function than **conventional therapy**.	4	Meng et al. 2018; Lee et al. 2017; Stinear et al. 2008; Desrosiers et al. 2005

Yellow statements indicate that the study results when grouped together are mixed or conflicting, some studies show benefit in favour of the intervention group, while others show no difference between groups.

For example:

DEXTERITY			
LoE	Conclusion Statement	RCTs	References
1a	There is conflicting evidence about the effect of **CIMT** to improve dexterity when compared to **conventional therapy** or **motor relearning programmes** during the acute/subacute phase poststroke.	4	Shah et al. 2016; Yoon et al. 2014; Boake et al. 2007; Ro et al. 2006

Outcome Measures

The Outcome Measure categorization is based on a recently published article:

Teasell, R., Flores-Sandoval, C., Mehrabi, S., Fleet, J. L., Payne, M. W., Viana, R., Peters, S., Bowman, A., & Safaei-Qomi, M. R. (2026). Outcome Measure Frequency in Stroke Rehabilitation Lower Extremity Randomized Controlled Trials and Its Correlation With Research and Clinical Practice Recommendations. Archives of physical medicine and rehabilitation, 107(6), 1416–1428. https://doi.org/10.1016/j.apmr.2026.02.009

Relevant outcome measures, used in 5 or more RCTs, were categorized based on the International Classification of Functioning, Disability and Health (ICF) Domains:

1. Body Functions and Structures
- 1.1 Motor recovery
- 1.2 Biomechanical Gait Measures
- 1.3 Biomechanical Balance Measures
- 1.4 Muscle Strength
- 1.5 Spasticity
- 1.6 Range of Motion
- 1.7 Neurophysiological Measures
- 1.8 Aerobic Measures
- 1.9 Sensory/Proprioception
- 1.10 Pain

2. Activities
- 2.1 Activities of Daily Living
- 2.2. Gait Speed
- 2.3 Gait Endurance
- 2.4 Functional Mobility
- 2.5 Balance
- 2.6 Falls and Fear of Falls

3. Participation
- 3.1 Quality of Life

Other Associated Outcome Measures
- A. Mood
- B. Fatigue and Sleep
- C. Cognition
- D. Upper Extremity

1. Body Functions and Structures

1.1 Motor Recovery

Outcome Measure	Number of RCTs	Description
Fugl-Meyer Assessment (FMA)	357	This stroke-specific, performance-based impairment index assesses motor function, sensation, balance, joint range of motion, and joint pain in patients with post-stroke hemiplegia through observed movements.
National Institutes of Health Stroke Scale (NIHSS)	50	This 15-item impairment scale assesses overall stroke severity across consciousness, vision, motor, sensory, language, and neglect items.
Brunnstrom Recovery Stages (BRS)	36	6-stage scale describing the typical sequence of motor recovery after stroke, from flaccidity to normal coordinated movement.
Rivermead Motor Assessment (RMA)	24	The assessment consists of three domains: gross function (13 items), leg and trunk movements (10 items), and arm movements (15 items). This three-part scale assesses gross function, leg/trunk movement, and arm movement after stroke.
Stroke Impairment Assessment Set (SIAS)	11	Multi-domain battery scoring motor function, muscle tone, sensory function, range of motion, pain, trunk control, and balance after stroke.
Canadian Neurological Scale	9	Assessment used to evaluate and monitor neurological status in patients during the acute phase of stroke. It assesses the level of consciousness, orientation, speech, facial weakness, and motor function of the arm and leg.
Chedoke McMaster Stroke Assessment Scale	7	Comprehensive measures used to assess both physical impairment and functional disability in individuals with stroke. It consists of two components: the Impairment Inventory, which evaluates recovery of the arm, hand, leg, foot, postural control, and shoulder pain, and the Activity Inventory, which assesses gross motor function and walking ability.
Clinical Neurological Deficit Scale	6	Bedside scale quantifying overall neurological deficit severity after a stroke event.
Scandinavian Stroke Scale (SSS)	5	Bedside scale rating consciousness, eye movement, arm/hand/leg motor power, orientation, speech, and gait after stroke.

1.2 Biomechanical Gait Measures

Outcome Measure	Number of RCTs	Description
Step Length/time/width	221	Instrumented gait-lab metrics of the distance, duration, and mediolateral spacing between successive footfalls.
Cadence	203	Number of steps taken per minute while walking
Stride Length/ time/ width	168	Distance, duration, and width of a full gait cycle (heel-strike to the next heel-strike of the same foot).
Gait Cycle phase/time (stance phase/swing phase)	111	Proportion or duration of the gait cycle spent with the foot on the ground (stance) versus moving forward (swing).

Support Time/Period (single and double support time)	109	Time spent bearing weight on one foot (single support) versus both feet (double support) during walking.
Gait Kinetics	106	Investigates the forces and moments of the gait cycle, i.e. ground reaction forces, center of pressure and distribution.
Gait Symmetry	95	Includes stance, spatial, temporal, swing symmetry/ symmetry in any gait phase.
Ankle Kinematics	71	Ankle Joint excursion throughout the stance phase or other phase of gait.
Knee Kinematics	55	Knee Joint excursion throughout the stance phase or other phase of gait.
Hip/pelvis Kinematics	55	Hip/pelvis Joint excursion throughout the stance phase or other phase of gait.
Symmetric/unilateral Weight Bearing	28	Distribution of body weight between the affected and unaffected legs while standing or walking.
Toe angle/ toe off	9	Angle of the foot at, or timing of, the point in gait when the toe leaves the ground.
Heel base placement/ heel rise	7	Position of heel contact at foot strike, or the point in gait when the heel lifts off the ground.

1.3 Biomechanical Balance Measures

Outcome Measure	Number of RCTs	Description
Postural Sway (PS)	43	Instrumented measure of the small movements of the body's center of pressure while standing still.
Limit of Stability	38	Maximum distance a person can intentionally lean or shift their center of gravity without losing balance or stepping.
Weight Distribution	26	Instrumented measure of how body weight is shared between the two feet while standing.
Dynamic Balance Parameters	26	Include quantitative metrics of postural stability during active movement, reflecting the temporal, spatial, and kinematic control of the center of mass such as sway area, sway path, maximal velocity, anteroposterior angle/mediolateral angles, and directional control.
Stabilometry Test (ST)	17	Force-platform test quantifying postural sway/stability while standing. Also known as Static Posturography or Static Balance Assessment.
Postural Control (PC)	13	General instrumented assessment of the body's ability to maintain an upright, stable position.
Overall Stability Test (OST)	8	Computerized platform test producing a composite score of standing balance stability.
Sensory Organization Test	8	Computerized posturography test that manipulates visual and support-surface conditions to assess how a person uses sensory input for balance.

1.4 Muscle Strength

Outcome Measure	Number of RCTs	Description
Isometric/Isokinetic/eccentric muscle force (including maximum voluntary isometric contraction)	122	Dynamometer-measured maximal force a muscle group produces during a static, constant-velocity, or lengthening contraction

Motricity Index	72	Weighted scale summing pinch grip, elbow flexion, and shoulder abduction (or ankle dorsiflexion, knee extension, hip flexion for the leg) to score limb motor strength after stroke.
Medical Research Council Scale (MRCS)	39	It is a measure of overall muscle strength a stroke survivor possesses. The measure consists of 33 functional tasks. Each task is then rated on a 4-point scale (0=cannot complete task, 3=completes task as well as the unaffected side).
Muscle Strength/ Resistance by dynamometer	14	Handheld or fixed dynamometer measurement of the force a muscle group can generate.
Muscle Thickness	14	Ultrasound or imaging measurement of muscle cross-sectional size, used as a proxy for muscle bulk/atrophy.
Trunk Muscle Strength	9	Dynamometer or manual testing of the force generated by trunk (core) musculature.
Gross Lower Limb Extension Strength	6	Measured force output of leg extensor muscle groups (e.g., knee/hip extensors) during a strength task.
One-Repetition Maximum	5	Heaviest load that can be lifted correctly for a single repetition of a given exercise.

1.5 Spasticity

Outcome Measure	Number of RCTs	Description
Modified Ashworth Scale (MAS)	178	6-point clinical scale rating resistance felt during passive muscle stretch, used to grade spasticity. It can be applied to both upper and lower limb muscle groups by passively moving a limb through its range of motion.
Ashworth Scale	24	Original 5-point clinical assessment used to evaluate muscle spasticity and resistance to passive movement in individuals.
Composite Spasticity Index	18	Assess upper and lower limb spasticity in individuals, and it evaluates spasticity using three components: tendon jerk, resistance to passive stretch, and clonus. The resistance-to-passive-stretch component is weighted more heavily because it best reflects muscle hypertonia.
Clonus Score	13	Clinical rating of the presence/duration of clonus (rhythmic involuntary muscle contractions) on rapid stretch
Tendon Reflex Scales	10	Clinical grading of the briskness of deep tendon reflexes, used as an indicator of neuromuscular excitability.
Tardieu Scale	9	Clinical scale measuring spasticity by comparing muscle reaction to stretch at different velocities.
Modified Modified Ashworth Scale	9	A revised version of the Modified Ashworth Scale developed to improve the reliability and clarity of spasticity assessment. It uses a 5-point scale (0-4) and removes the 1+ category from the Modified Ashworth Scale.
Muscle Tone	9	General clinical rating of resting muscle tension/resistance to passive movement.
Modified Tardieu Scale (MTS)	7	Refined Tardieu Scale assessing spasticity by testing muscle response to slow versus fast passive stretch. The MTS is considered more sensitive to the velocity-dependent nature of spasticity than the Ashworth-based scales.

1.6 Range of Motion

Outcome Measure	Number of RCTs	Description

Active Range of Motion (AROM)	74	Degrees of joint movement a person can achieve using their own muscle effort, measured with a goniometer.
Passive Range of Motion (PROM)	57	Degrees of joint movement achievable when an examiner moves the joint without the person's muscular effort.

1.7 Neurophysiological Measures

Outcome Measure	Number of RCTs	Description
Peripheral Neurophysiology (EMG / NCS measures)	104	Electromyography and nerve conduction study measures peripheral nerve and muscle electrical activity. Includes Hmax/Mmax ratio, Compound Muscle Action Potential, M-wave, Motor Action Potential, Electromyography amplitude/latency parameters, Nerve conduction intensity and duration measurements.
Physiological Parameter	61	Includes lab tests, blood markers, weight, body mass index, body composition and vital signs (except heart rate; see Aerobic measures).
Central Neurophysiology (TMS-based corticospinal measures)	34	Includes MEP amplitude, Resting Motor Threshold (RMT), Corticospinal / Corticomotor excitability.
Functional Magnetic Resonance Imaging (fMRI) Parameters	17	Brain imaging measures neural activation patterns based on blood-oxygen-level changes during tasks or at rest.
Electroencephalography (EEG) Parameters	11	Scalp-recorded measures of the brain's electrical activity.

1.8 Aerobic Measures

Outcome Measure	Number of RCTs	Description
Peak Oxygen Consumption (VO2)	41	Highest rate of oxygen uptake achieved during a maximal or symptom-limited exercise test, reflecting cardiorespiratory fitness.
Heart Rate	31	Number of heart beats per minute, measured at rest or during exercise.
Respiratory Measures (Forced Vital Capacity, etc.)	23	Pulmonary function tests (e.g., forced vital capacity) assess lung volume and breathing capacity.
Walking Economy	22	Measures energy costs while the individual is walking.
Rate of Perceived Exertion (RPE)/ Borg RPE	16	Self-reported rating of how hard a person feels they are working during exercise, typically on the Borg scale.
Peak Work Rate (Peak power output (PPO))	10	Highest mechanical power output (e.g., watts on a cycle ergometer) achieved during a maximal exercise test.
Physiological Cost Index (PCI)	9	Ratio of the rise in heart rate during walking-to-walking speed, used as an indirect index of walking energy cost.
Oxygen Consumption (VO2) Max	9	Maximum rate of oxygen consumption an individual can utilize during intense exercise.
Oxygen Consumption (VO2) Ventilatory Threshold	9	Exercise intensity at which ventilation increases disproportionately to oxygen consumption, marking a shift toward anaerobic metabolism.
Exercise Tolerance Test	5	Graded exercise tests used to evaluate cardiovascular response and capacity for physical exertion.

1.9 Sensory/Proprioception

Outcome Measure	Number of RCTs	Description
Lower Limb Proprioception	7	General assessment of the ability to sense the position and movement of the leg/foot without vision.
Joint Position Sense Test (JPST)	5	Test of a person's accuracy in reproducing or detecting a joint position without visual feedback.

1.10 Pain

Outcome Measure	Number of RCTs	Description
Pain Visual Analogue Scale (VAS)	13	Self-reported pain intensity marked on a continuous line, typically 0 (no pain) to 10 (worst pain).
Pain- No Scale Specified	6	Pain reported by participants without a named or standardized measurement tool.
Pain Numeric Rating Scale (NRS)	5	Self-reported pain intensity is rated as a whole number, typically 0 (no pain) to 10 (worst pain).

2. Activities

2.1 Activities of Daily Living

Outcome Measure	Number of RCTs	Description
Barthel Index (BI)	219	Measure of functional independence in individuals with stroke and other neurological conditions. It assesses performance in 10 activities of daily living (ADLs), including feeding, bathing, grooming, dressing, continence, toileting, transfers, mobility, and stair climbing.
Functional Independence Measure (FIM)	126	Assessment of disability and functional independence commonly used in stroke rehabilitation. It consists of 18 items grouped into two domains: Motor (13 items) and Cognitive (5 items), covering areas such as self-care, mobility, communication, and social cognition.
Modified Barthel Index (MBI)	95	Expanded, more finely graded version of the Barthel Index for scoring independence in daily activities.
Modified Rankin Scale (MRS)	57	It is a single-item measure of global disability and functional independence after stroke. The MRS assesses overall functional outcome relative to a person's pre-stroke lifestyle rather than performance on specific tasks.
Nottingham Extended Activities of Daily Life (NEADL)	22	It is a measure of a stroke survivor’s independence with regards to their performance on various activities of daily living. The measure consists of 22 functional tasks.
Frenchay Activities Index (FAI)	16	Questionnaire measuring the frequency of participation in everyday domestic, leisure, and work-related activities. Higher scores indicate greater independence and engagement in everyday life.
Goal Attainment Scale	7	Individualized scale measuring the extent to which a person's own personalized rehabilitation goals were achieved.
Subjective Index of Physical and Social Outcome (SIPSO)	5	Self-report questionnaire measuring perceived physical independence and social integration after stroke.

Human Activity Profile	5	Self-report questionnaire estimating maximal activity levels and average daily energy expenditure.

2.2 Gait Speed

Outcome Measure	Number of RCTs	Description
10-Metre Walk Test (10MWT)	436	Time taken to walk 10 metres at a comfortable or fast pace, used to calculate walking speed.
Gait Speed as a kinematic parameter	238	Refers to gait speed measured by a computerized system, such as GAITRite system, OptoGait, Gait Mat II, etc.
5-Meter Walk Test (5MWT)	24	Time taken to walk 5 metres, used to calculate walking speed.
Unspecified walking speed	15	Walking speed is reported without specifying the distance or method used to obtain it.
6-Meter Walk Test	13	Time taken to walk 6 meters, used to calculate walking speed.
Treadmill walking speed	7	Walking speed measured or set on a treadmill rather than overground.
3-Meter Walk Test	5	Time taken to walk 3 meters, used to calculate walking speed.
8-Metre Walk Test	5	Time taken to walk 8 meters, used to calculate walking speed.

2.3 Gait Endurance

Outcome Measure	Number of RCTs	Description
6-Min Walk Test (6MWT)	288	Total distance walked in 6 minutes, used to assess walking endurance and sub-maximal aerobic capacity.
2-Min Walk Test	30	Total distance walked in 2 minutes, a shorter alternative measure of walking endurance.
Overground Walking Distance 3-Min Walk Test	16	Total distance walked over ground in 3 minutes, used to assess walking endurance.
Daily Steps	15	Number of steps taken over a day, typically recorded with an accelerometer or step counter.

2.4 Functional Mobility

Outcome Measure	Number of RCTs	Description
Timed Up & Go Test (TUG)	395	Time taken to rise from a chair, walk 3 meters, turn, walk back, and sit down, assessing basic sequential functional mobility.
Functional Ambulation Category (FAC)	185	6-point clinical scale used to assess walking ability and the level of assistance required during ambulation. The FAC focuses on the amount of human support needed rather than walking speed or endurance.
Rivermead Mobility Index (RMI)	84	15-item scale assessing a range of mobility skills from turning in bed to running.
Tinetti Scale (TGS)	42	Performance-based scale scoring balance and gait tasks to estimate fall risk. Includes balance and gait components; also known as Performance-Oriented Mobility Assessment (POMA).

Dynamic Gait Index	41	8-item performance test assessing the ability to adapt gait to changing task demands (e.g., speed changes, turning head, obstacles).
Stair Climb Test (SCT)	32	Time taken to ascend and/or descend a flight of stairs.
Five Time Sit-to-Stand Test (FTSTS)	29	Time taken to stand up and sit down from a chair five times consecutively, without using arms if possible.
Sit-to-Stand Test (STS)	25	Timed or repetition-based test of the ability to rise from and/or return to a seated position.
Motor Assessment Scale	20	Performance-based measures used to assess functional motor recovery after stroke. It evaluates 8 everyday motor tasks, including bed mobility, sitting balance, standing, walking, upper arm function, and hand activities.
Stroke Rehabilitation Assessment of Movement (SRAM)	18	Is a measure of how well stroke patients can perform functional tasks. This measure consists of 30 functional tasks which are then subdivided into 5 subsections: supine, sitting, standing, standing (while gripping a stable support) and standing plus walking activities.
Dual Task	17	Assessment that combines a task with a walking test (secondary task could be cognitive or motor).
Functional Gait Assessment	17	10-item scale assessing postural stability during varied walking tasks.
Step Test	15	Number of times a person can tap one foot on a step within a set time, testing dynamic single-leg balance.
Modified Motor Assessment Scale	13	A revised version of the Motor Assessment Scale developed to improve scoring consistency and ease of use. The general tonus item was removed, and some item descriptions were clarified while maintaining the original focus on functional motor performance after stroke.
Community Walking Performance	12	Assessment of walking ability and confidence under real-world community conditions (e.g., outdoors, obstacles, distances).
Modified Rivermead Mobility Index (MRMI)	11	Shortened/adapted version of the Rivermead Mobility Index for scoring mobility skills.
Short Physical Performance Battery (SPPB)	11	Composite test of balance, gait speed, and chair-stand performance, commonly used to assess physical function in older adults.
Mobility Scale	8	General scale rating a person's overall level of mobility or mobility-related independence.
Modified Emory Functional Ambulation Profile	8	Adapted timed test of walking performance across varied terrains and obstacles.
30-Second Sit-to-Stand Test	8	Number of times a person can stand fully and sit back down within 30 seconds
Emory Functional Ambulatory Category	7	Categorical rating of the level of assistance needed for functional ambulation.
Wisconsin Gait Scale	7	Is a measure that evaluates the gait parameters and walking abilities of a stroke patient.
Rivermead Gait Assessment	5	10-item scale assessing postural stability during varied walking tasks.

2.5 Balance

Outcome Measure	Number of RCTs	Description
Berg Balance Scale (BBS)	488	Assessment used to evaluate balance and postural control in individuals with stroke. It consists of 14 functional tasks assessing both static and dynamic balance.
Trunk Impairment Scale (TIS)	76	17-item, performance-based assessment of static sitting balance, dynamic sitting balance, and trunk coordination following stroke. Scores range from 0–23, with higher scores indicating better trunk function
Functional Reach Test	63	A clinical outcome measure and assessment tool for ascertaining dynamic balance in a simple task. It measures the distance between the length of an outstretched arm in a maximal forward reach, while maintaining a fixed base of support.
Postural Assessment Stroke Scale (PASS)	48	An outcome measure specifically designed to assess and monitor postural control after stroke. It contains 12 four-level items of varying difficulty for assessing ability to maintain or change a given lying, sitting, or standing posture.
Static Balance Index (SBI)-Parameters (Sitting Balance)	44	Instrumented or clinical parameters quantifying steadiness while maintaining a seated position.
Trunk Control Test (TCT)	25	Is a measure that assesses the level of motor impairment a stroke patient has in the trunk/abdominal region. This measure consists of 4 functional tasks. For each task the patient receives points for a maximum of 100 points
Mini Balance Evaluation Systems Test	20	Is a shortened measure of balance, including assessments related to anticipatory postural adjustments, reactive postural control, sensory orientation, and dynamic gait.
Single Leg Stance (SLS)	14	Refers to balance control
Romberg's Test of Balance	13	Is an assessment of balance that measures participants' postural sway or stability. The test involves standing with your feet together while an observer notes any body movement and is conducted with both eyes open and closed
Brunel Balance Assessment	12	Hierarchical scale assessing sitting, standing, and stepping balance ability.
Lateral Reach Test	8	Maximum distance a person can reach sideways while standing without losing balance.
Modified Functional Reach Tests	8	Assessment of the maximum distance a person can reach sideways while standing without losing balance.
Balance (No Specific Scale)	6	General or unspecified assessment of balance ability.
Four Square Step Test	6	Is a measure of dynamic balance that assesses a participant's ability to step over objects when approaching from the front, the side, and from the back.

2.6 Falls and Fear of Falls

Outcome Measure	Number of RCTs	Description
Activities-Specific Balance Confidence Scale (ABC Scale)	60	Self-report questionnaire rating confidence in performing daily activities without losing balance or falling.

The Falls Efficacy Scale – International (FES-I)	38	It is a measure of fear of falling or concerns about falling. It is a 16-item questionnaire, useful to the researchers and clinicians interested in fear of falling, with a score ranging from a minimum of 16 to a maximum of 64.
Rate of Falls (RoF)	19	Number of falls recorded over a defined follow-up period
Fall Risk	15	General estimate or index of the likelihood of experiencing a fall.

3. Participation

3.1 Quality of Life

Outcome Measure	Number of RCTs	Description
Stroke Impact Scale (SIS)	72	It is a stroke-specific, self-report, health status measure designed to assess multidimensional stroke outcomes, including strength, hand function, Activities of Daily Living / Instrumental Activities of Daily Living (ADL/IADL), mobility, communication, emotion, memory and thinking, and participation.
Short Form-36 (SF-36)	53	Patient-reported measure of health-related quality of life (HRQoL). It consists of 36 items across eight domains: physical functioning, role limitations due to physical health, bodily pain, general health, vitality, social functioning, role limitations due to emotional problems, and mental health.
Stroke Specific Quality of Life	45	The Stroke Specific Quality of Life scale (SS-QOL) is a patient-centered outcome measure intended to provide an assessment of health-related quality of life (HRQOL) specific to patients with stroke.
EuroQol Group Standardised Measure of Quality of Life (EQ-5-D)	39	It is a non-disease-specific measure of health-related quality of life consisting of six domains which include mobility, self-care, main activity, social relationships, pain, mood and three levels within each domain
Nottingham Health Profile	13	It is a measure of any health-related problems. It consists of two parts. The first part covers six areas including sleep, physical mobility, energy, pain, emotional reactions, and social isolation. The second part focuses on areas of daily life that would be most impacted by health status including employment, social life, interests, etc.
Clinical Global Impression of Change (CGI)	11	Clinician- or patient-rated global judgment of overall change in condition based on baseline.
Short Form-12 (SF12)	9	A shortened version of the SF-36 designed to provide a quick assessment of health-related quality of life. It contains 12 items derived from the SF-36.
Caregiver Strain Index	9	Questionnaire measuring the level of strain experienced by an informal caregiver.
EuroQol Visual Analogue Scale (EQ-VAS)	8	Single visual analogue scale on which respondents rate their overall current health state.
World Health Organization Quality of Life (WHOQOL-BREF)	6	26-item generic questionnaire assessing quality of life across physical, psychological, social, and environmental domains.

Other Associated Outcome Measures

A. Mood

Outcome Measure	Number of RCTs	Description
Hospital Anxiety and Depression Scale (HADS)	27	A self-report screening tool used to identify symptoms of anxiety and depression in individuals with medical conditions, including stroke. It consists of 14 items, with 7 items assessing anxiety (HADS-A) and 7 items assessing depression (HADS-D).
Beck Depression Inventory (BDI)	14	Self-report questionnaire for assessing the severity of depressive symptoms in adolescents and adults, including individuals with stroke. It consists of 21 items covering emotional, cognitive, and physical symptoms of depression.
Geriatric Depression Scale (GDS) - Short	11	Self-report screening tool designed to identify depression in older adults, including individuals recovering from stroke. The original version contains 30 yes/no questions that assess mood, interests, life satisfaction, and other symptoms of depression.
Patient Health Questionnaire-9 (PHQ-9)	9	9-item self-report questionnaire screening for grading severity of depressive symptoms.
Hamilton Rating Scale for Depression (HRSD)	8	Scale used to stratify severity of depression, to guide treatment and inform progress in patients with already identified depressive disorder
Center for Epidemiological Studies of Depression Scale	6	20-item self-report questionnaire screening for depressive symptoms in the general population
General Self-Efficacy Scale	5	Self-report questionnaire measuring a person's belief in their own ability to cope with and manage life's demands.

B. Fatigue and Sleep

Outcome Measure	Number of RCTs	Description
Fatigue Severity Scale	11	9-item scale measures the severity of fatigue and its effect on a person's activities and lifestyle in patients with a variety of disorders.

C. Cognition

Outcome Measure	Number of RCTs	Description
Montreal Cognitive Assessment (MoCA)	22	A cognitive screening tool designed to detect mild cognitive impairment (MCI) and subtle cognitive deficits that may not be identified by the Mini-Mental State Examination (MMSE). It evaluates multiple cognitive domains, including attention, concentration, executive function, memory, language, visuospatial ability, abstraction, calculation, and orientation
Mini Mental State Examination (MMSE)	23	Screening tools for assessing cognitive function and detecting cognitive impairment. It consists of 11 tasks that evaluate orientation, attention, memory, language, calculation, and visuospatial abilities.

Stroop test	11	Cognitive test measuring selective attention and processing speed via interference between word reading and color naming.
Trail Making Test (A&B)	11	Timed test of visual attention and task-switching, connecting numbered (Part A) or alternating numbered and lettered (Part B) circles in sequence.
Digit/Spatial span	9	Test short-term memory capacity by recalling increasingly long sequences of digits or spatial locations.

D. Upper Extremity

Outcome Measure	Number of RCTs	Description
Fugl-Meyer Assessment Upper Extremity (FMA-UE)	52	Upper-limb subsection of the Fugl-Meyer Assessment scoring arm and hand motor impairment after stroke.
Grip force	26	Dynamometer measurement of the maximal force generated during a hand grip.
9-Hole Peg Test (9HPT)	14	Simple, performance-based tests used to assess fine motor dexterity and finger coordination of the upper extremity. During the test, individuals place and remove nine pegs from a pegboard as quickly as possible using one hand at a time.
Wolf Motor Function Test (WMFT)	12	It quantifies upper extremity motor ability in stroke survivors through timed and functional tasks.
Box and Block Test (BBT)	11	A simple and widely used assessment of unilateral gross manual dexterity in individuals with stroke and other neurological conditions. During the test, participants are required to transfer as many blocks as possible, one at a time, from one compartment of a box to another within 60 seconds.
Ashworth Scale/modified Ashworth Scale for Upper Extremity	9	Is a measure of resistance to passive movement in stroke survivors. In the context of upper extremity, it is applied to upper limb muscles.
Action Research Arm Test (ARAT)	9	Assessment used to evaluate upper limb function and activity limitations. It consists of 19 items divided into four domains: grasp, grip, pinch, and gross movement.
Brunnstrom for Upper Extremity	6	Upper-limb application of the Brunnstrom stages describing the sequence of motor recovery of the arm and hand.
Range of Motion for Upper Extremity	6	It is the extent or limit to which a part of the body can be moved around a joint or a fixed point (Shoulder, elbow, wrist, or hand mobility)

Chapter 9: Lower Extremity Motor Rehabilitation Interventions

Neurodevelopmental Techniques and Motor Relearning

Adopted from: http://www.bobathconcept.eu/en/main-site/

There are several approaches considered to be neurodevelopmental techniques including the Bobath concept Approach (BCA). The Bobath concept is a comprehensive, problem-solving treatment approach that focuses on motor recovery (e.g. function, movement and tone) of an individual's affected side after a lesion in the central nervous system (Michielsen et al., 2019). Prior to its introduction in the 1950's, stroke rehabilitation largely assumed

a compensatory approach towards the unaffected side for rehabilitation (Kollen et al., 2009). The Bobath concept like other neurodevelopmental techniques relies on the tenets of neuroplasticity, in that motor recovery of the affected side is possible through individualised treatment plans that focus on how tasks are completed, facilitation of movements through therapeutic handling, movement analysis, modification of the environment and appropriate use of verbal cues from therapists (Michielsen et al., 2019).

The motor relearning programme employs practice of task-specific activities to remediate specific motor skills needed to perform that task. Motor tasks are practiced in context relevant environments to enhance sensory input and modulate performance (Pandian et al., 2012).

A total of eighteen RCTs were found that evaluated neurodevelopmental techniques and motor relearning for lower extremity motor rehabilitation. Five RCTs compared Bobath Concept Approach with Conventional Therapies (Balkan et al. 2024; Yazici et al. 2021; Kilinc et al. 2016; Wang et al. 2005; Gelber et al. 1995). One RCT compared Early Bobath Approaches with Late Bobath Approaches (Tang et al. 2014). Two RCTs compared Bobath Concept Approach with Task-Specific Training with Task-Specific Training (Brock et al. 2011; Mudie et al. 2002). Three RCTs compared Motor Relearning Programmes with Conventional Therapy or Sham (Ghrouz et al. 2024; Chan et al. 2006; Bourbonnais et al. 2002). Two RCTs compared Motor Relearning with Bobath Concept Approach (Van Vliet et al. 2005; Langhammer & Stanghelle 2000). One RCT compared Bobath Concept Approach with Proprioceptive Neuromuscular facilitation (Krukowska et al. 2016). Two RCTs compared Bobath Concept Approach Combined with Other Therapies with Bobath or Conventional Therapy (Ashraf et al. 2024; Covcic et al. 2022). One RCT compared Bobath Concept Approach with Task-Specific Training (Sutcu et al. 2023).

In addition, 22 RCTs in which neurodevelopmental techniques and motor relearning formed part of a combined or comparative intervention are cross-referenced at the end of Table 1; their primary listings appear in other tables.

The methodological details and results of all eighteen RCTs are presented in Table 1.

Table 1. RCTs Evaluating Neurodevelopmental Techniques and Motor Relearning for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Bobath Concept Approach vs Conventional Therapies		
Balkan et al. (2024) RCT (4) Nstart=88 Nend=81 TPS=Acute A vs 0	E: Bobath based physical therapy program C: Conventional physiotherapy program Duration: 60 mins/d, 5d/wk, during hospitalization	E vs C: TIS static (+exp) dynamic (+exp) coordination (+exp) total (+exp) Berg Balance Scale (+exp) Modified Ashworth Scale (+exp) Functional Independence Measurement Motor Subscale (+exp) Sitting ability (+exp)
Yazici et al. (2021) RCT (6) Nstart=41 Nend=39 TPS=Acute A vs 0	E: Neurodevelopmental technique (BCA) C: Standard rehabilitation Duration: 60min/d, 5d/wk Bobath & 5d/wk Standard Rehabilitation	E vs C: Stroke Rehabilitation Assessment of Movement Scale (+exp) Upper Extremity (-) Lower Extremity (-) Trunk (+exp) Trunk Impairment Scale (+exp) Berg Balance Scale (+exp) Barthel Index (+exp) hospitalization period (+exp)

Kilinc et al. (2016) RCT (6) Nstart=22 Nend=19 TPS=Chronic A vs B	E: BCA C: Conventional techniques (strengthening, stretching, weight transfer, range of motion) Duration: 60min/d, 3d/wk, for 12wks	E vs C: Trunk Impairment Scale (-) Stroke rehabilitation assessment of movement (-) 10-Meter walking test (-) Berg Balance Scale (-) Functional Reach test (-) Timed Up-and-Go test (-)
Wang et al. (2005) RCT (6) Nstart=44 Nend=44 TPS=Acute A vs B	E: BCA C: Orthopaedic approach (passive, assistive and progressive resistive exercise) Duration: 40min/d, 5d/wk for 4wks	E vs C: Patients with stroke spasticity: Stroke Impairment Assessment set Lower extremity motor control (-) Tone (+exp) Motor Assessment Scale (+exp) Berg Balance Scale (-) Stroke Impact Scale (+exp) Patients with relative recovery: Stroke Impairment Assessment set (-) Motor Assessment Scale (+exp) Berg Balance Scale (+exp) Stroke Impact Scale (+exp)

Nstart=12 Nend=12 TPS=Chronic A + B vs A Primary listing: Table 15 (Biofeedback)	Duration: 40min/d, 3d/wk for 5wk	Gait velocity (-) Range of motion (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Bobath Concept Approach may not have a difference in efficacy when compared to Conventional Therapies for improving motor recovery.	1	Wang et al. 2005
2	Motor relearning with lower limb force-feedback may not have a difference in efficacy when compared to Motor relearning with upper limb force-feedback for improving motor recovery.	1	Bourbonnais et al. 2002
1a	Motor Relearning may not have a difference in efficacy when compared to Bobath Concept Approach for improving motor recovery.	2	Van Vliet et al. 2005; Langhammer & Stanghelle 2000
2	Functional (adaptive) movement approach may not have a difference in efficacy when compared to functional approach for lower limb dressing for improving motor recovery.	1	Mew et al. 2010
1b	Repetitive transcranial magnetic stimulation with Motor relearning procedure may produce greater improvements in motor recovery than Motor relearning procedure with Conventional rehabilitation.	1	Chen et al. 2023b
1b	Bobath with dry needling may produce greater improvements in motor recovery than Bobath.	1	Sanchez-Mila et al. 2018
1b	Body weight supported Treadmill with Bobath physiotherapy may not have a difference in efficacy when compared to Bobath physiotherapy for improving motor recovery.	1	Eich et al. 2004

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Bobath Concept Approach may not have a difference in efficacy when compared to Conventional Therapies for improving biomechanical gait measures.	1	Gelber et al. 1995
2	Neurodevelopmental Bobath Concept Approach may produce greater improvements in biomechanical gait measures than proprioceptive neuromuscular facilitation method (proprioceptive neuromuscular facilitation).	1	Krukowska et al. 2016
1b	Bobath Concept Approach may not have a difference in efficacy when compared to Task-Specific Training for improving biomechanical gait measures.	1	Sutcu et al. 2023

2	Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may produce greater improvements in biomechanical gait measures than Balance exercises with neurodevelopmental treatment.	1	Cui et al. 2024
2	Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may produce greater improvements in biomechanical gait measures than gaze stabilization exercises with neurodevelopmental treatment.	1	Cui et al. 2024
2	Cervical mobilization with Bobath neurodevelopmental therapy may produce greater improvements in biomechanical gait measures than Sham spinal mobilization with Bobath neurodevelopmental therapy.	1	Dengiz et al. 2024
1b	Matrix Rhythm Therapy (vibration) from thoracic spine to lower extremity with Bobath Therapy may not have a difference in efficacy when compared to Bobath Therapy for improving biomechanical gait measures.	1	Unal et al. 2021
1b	Action observation of community ambulation with Functional training based on neurodevelopmental techniques may not have a difference in efficacy when compared to Landscape observation with Functional training based on neurodevelopmental techniques for improving biomechanical gait measures.	1	Park et al. 2017b
1b	Gait training with Rhythmic auditory stimulation and conventional therapy (bobath) may not have a difference in efficacy when compared to Gait training with conventional therapy (bobath) for improving biomechanical gait measures.	1	Suh et al. 2014b
2	There is conflicting evidence about the effect of Musical motor feedback with Conventional gait therapy and Neurodevelopmental therapy when compared to Conventional gait therapy with Neurodevelopmental therapy for improving biomechanical gait measures.	1	Schauer et al. 2003

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Bobath Concept Approach with Task-Specific Training may not have a difference in efficacy when compared to Task-Specific Training for improving biomechanical balance measures.	1	Mudie et al. 2002

2	Sensory training with Trunk-centred Bobath exercise may not have a difference in efficacy when compared to Trunk-centred Bobath exercise for improving activities of daily living.	1	Karaca et al. 2024

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Bobath Concept Approach when compared to Conventional Therapies for improving gait speed.	2	Kilinc et al. 2016; Gelber et al. 1995
1b	Bobath Concept Approach with Task-Specific Training may produce greater improvements in gait speed than Task-Specific Training.	1	Brock et al. 2011
2	Motor relearning with lower limb force-feedback may produce greater improvements in gait speed than Motor relearning with upper limb force-feedback.	1	Bourbonnais et al. 2002

1b	Bobath Concept Approach may not have a difference in efficacy when compared to Task-Specific Training for improving gait speed.	1	Sutcu et al. 2023
2	Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may produce greater improvements in gait speed than Balance exercises with neurodevelopmental treatment.	1	Cui et al. 2024
2	Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may produce greater improvements in gait speed than gaze stabilization exercises with neurodevelopmental treatment.	1	Cui et al. 2024
2	Cervical mobilization with Bobath neurodevelopmental therapy may produce greater improvements in gait speed than Sham spinal mobilization with Bobath neurodevelopmental therapy.	1	Dengiz et al. 2024
1b	Sustained natural apophyseal glides with neurodevelopmental techniques may not have a difference in efficacy when compared to Maitland mobilization with neurodevelopmental techniques for improving gait speed.	1	Kim et al. 2024c
1b	Dry needling with Neurodevelopmental therapy may produce greater improvements in gait speed than Neurodevelopmental therapy.	1	Kucuktepe et al. 2023
1b	Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques may produce greater improvements in gait speed than Talocrural joint only mobilization with neurodevelopmental techniques.	1	Buyukturan et al. 2022
1b	Muscle strengthening training to non-paralytic dorsiflexion muscles with neurodevelopmental therapy may not have a difference in efficacy when compared to Muscle strengthening training to paralytic dorsiflexion muscles with neurodevelopmental therapy for improving gait speed.	1	Park et al. 2021a
1b	Matrix Rhythm Therapy (vibration) from thoracic spine to lower extremity with Bobath Therapy may produce greater improvements in gait speed than Bobath Therapy.	1	Unal et al. 2021
1b	Action observation of community ambulation with Functional training based on neurodevelopmental techniques may produce greater improvements in gait speed than Landscape observation with Functional training based on neurodevelopmental techniques.	1	Park et al. 2017b
1b	Gait training with Rhythmic auditory stimulation and conventional therapy (bobath) may not have a difference in efficacy when compared to Gait training with conventional therapy (bobath) for improving gait speed.	1	Suh et al. 2014b
1b	Body weight supported Treadmill with Bobath physiotherapy may produce greater improvements in gait speed than Bobath physiotherapy.	1	Eich et al. 2004
2	Musical motor feedback with Conventional gait therapy and Neurodevelopmental therapy may not have a difference in efficacy when compared to Conventional gait therapy with Neurodevelopmental therapy for improving gait speed.	1	Schauer et al. 2003
2	Motor relearning with electromyography biofeedback may not have a difference in efficacy when compared to Motor relearning for improving gait speed.	1	Mulder et al. 1986

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Bobath Concept Approach with Task-Specific Training may not have a difference in efficacy when compared to Task-Specific Training for improving gait endurance.	1	Brock et al. 2011
2	Motor relearning with lower limb force-feedback may produce greater improvements in gait endurance than Motor relearning with upper limb force-feedback.	1	Bourbonnais et al. 2002
1b	Motor Relearning may not have a difference in efficacy when compared to Bobath Concept Approach for improving gait endurance.	1	Van Vliet et al. 2005
1b	Sustained natural apophyseal glides with neurodevelopmental techniques may not have a difference in efficacy when compared to Maitland mobilization with neurodevelopmental techniques for improving gait endurance.	1	Kim et al. 2024c
2	Sensory training with Trunk-centred Bobath exercise may not have a difference in efficacy when compared to Trunk-centred Bobath exercise for improving gait endurance.	1	Karaca et al. 2024
2	Whole body vibration with Neurodevelopmental treatment may produce greater improvements in gait endurance than Neurodevelopmental treatment.	1	Duray et al. 2023
1b	Inspiratory Muscle Training with Neurodevelopmental Bobath Treatment may not have a difference in efficacy when compared to Neurodevelopmental Bobath Treatment for improving gait endurance.	1	Aydogan Arslan et al. 2022
1b	Body weight supported Treadmill with Bobath physiotherapy may produce greater improvements in gait endurance than Bobath physiotherapy.	1	Eich et al. 2004

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Bobath Concept Approach when compared to Conventional Therapies for improving functional mobility.	3	Yazici et al. 2021; Kilinc et al. 2016; Wang et al. 2005
1b	Early Bobath Approaches may produce greater improvements in functional mobility than Late Bobath Approaches.	1	Tang et al. 2014

Other Associated Outcome Measures

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Motor relearning with lower limb force-feedback may not have a difference in efficacy when compared to Motor relearning with upper limb force-feedback for improving upper extremity function.	1	Bourbonnais et al. 2002
1b	Motor Relearning may not have a difference in efficacy when compared to Bobath Concept Approach for improving upper extremity function.	1	Van Vliet et al. 2005
1b	Dry needling with Neurodevelopmental therapy may produce greater improvements in upper extremity function than Neurodevelopmental therapy.	1	Kucuktepe et al. 2023

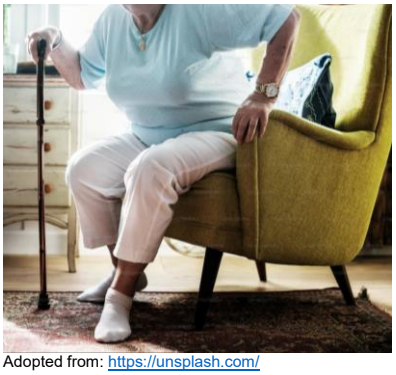
Key Points

- Bobath Concept Approach may be beneficial for improving spasticity, activities of daily living, balance, and quality of life, but not motor recovery and biomechanical gait measures, after stroke when compared to Conventional Therapies; the literature is mixed regarding gait speed and functional mobility.
- Early Bobath Approaches may be beneficial for improving functional mobility and balance after stroke when compared to Late Bobath Approaches.
- Bobath Concept Approach with Task-Specific Training may be beneficial for improving gait speed, but not biomechanical balance measures, activities of daily living, gait endurance, and balance, after stroke when compared to Task-Specific Training.
- Motor Relearning Programmes may be beneficial for improving biomechanical balance measures, activities of daily living, and balance, but not functional mobility, after stroke when compared to Conventional Therapy or Sham.

- Motor relearning with lower limb force-feedback may be beneficial for improving gait speed and gait endurance, but not motor recovery and functional mobility, after stroke when compared to Motor relearning with upper limb force-feedback.
- Motor Relearning may not be beneficial for improving motor recovery, spasticity, sensory and proprioceptive function, activities of daily living, gait endurance, functional mobility, and quality of life after stroke when compared to Bobath Concept Approach.
- Neurodevelopmental Bobath Concept Approach may be beneficial for improving biomechanical gait measures after stroke when compared to proprioceptive neuromuscular facilitation method (proprioceptive neuromuscular facilitation).
- Bobath Concept Approach Combined with Other Therapies may be beneficial for improving range of motion and balance, but not functional mobility, after stroke when compared to Bobath or Conventional Therapy.
- Bobath Concept Approach may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, muscle strength, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Task-Specific Training.
- Functional (adaptive) movement approach may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to functional approach for lower limb dressing.
- Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and functional mobility, but not balance and falls and fear of falling, after stroke when compared to Balance exercises with neurodevelopmental treatment.
- Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and functional mobility, but not balance and falls and fear of falling, after stroke when compared to gaze stabilization exercises with neurodevelopmental treatment.
- Cervical mobilization with Bobath neurodevelopmental therapy may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and functional mobility after stroke when compared to Sham spinal mobilization with Bobath neurodevelopmental therapy.
- Sustained natural apophyseal glides with neurodevelopmental techniques may not be beneficial for improving biomechanical balance measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Maitland mobilization with neurodevelopmental techniques.
- Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) may be beneficial for improving range of motion, but not balance, after stroke when compared to Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy).
- Sensory training with Trunk-centred Bobath exercise may be beneficial for improving sensory and proprioceptive function, but not activities of daily living, gait endurance, and balance, after stroke when compared to Trunk-centred Bobath exercise.
- Motor Relearning Program with Obstacle walking may be beneficial for improving spasticity and functional mobility after stroke when compared to Motor Relearning Program.
- Whole body vibration with Neurodevelopmental treatment may be beneficial for improving gait endurance, but not neurophysiological measures and aerobic measures, after stroke when compared to Neurodevelopmental treatment.
- Repetitive transcranial magnetic stimulation with Motor relearning procedure may be beneficial for improving motor recovery, spasticity, and neurophysiological measures, but not functional mobility, after stroke when compared to Motor relearning procedure with Conventional rehabilitation.
- Dry needling with Neurodevelopmental therapy may be beneficial for improving range of motion, gait speed, and balance after stroke when compared to Neurodevelopmental therapy; the literature is mixed regarding spasticity.
- Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques may be beneficial for improving muscle strength, gait speed, functional mobility, and balance after stroke when compared to Talocrural joint only mobilization with neurodevelopmental techniques.

- Inspiratory Muscle Training with Neurodevelopmental Bobath Treatment may not be beneficial for improving aerobic measures, gait endurance, and functional mobility after stroke when compared to Neurodevelopmental Bobath Treatment; the literature is mixed regarding balance.
- Muscle strengthening training to non-paralytic dorsiflexion muscles with neurodevelopmental therapy may not be beneficial for improving neurophysiological measures, gait speed, and functional mobility after stroke when compared to Muscle strengthening training to paralytic dorsiflexion muscles with neurodevelopmental therapy.
- Matrix Rhythm Therapy (vibration) from thoracic spine to lower extremity with Bobath Therapy may be beneficial for improving spasticity, range of motion, gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Bobath Therapy.
- Segmental mid-thoracic mobilization with neurodevelopmental therapy may be beneficial for improving quality of life, but not biomechanical balance measures and aerobic measures, after stroke when compared to Foam roller exercises with neurodevelopmental therapy.
- Modified constraint-induced movement therapy with Neurodevelopmental therapy may be beneficial for improving muscle strength, but not quality of life, after stroke when compared to neurodevelopmental therapy.
- Bobath with dry needling may be beneficial for improving motor recovery, biomechanical balance measures, and spasticity after stroke when compared to Bobath.
- Action observation of community ambulation with Functional training based on neurodevelopmental techniques may be beneficial for improving gait speed, functional mobility, and falls and fear of falling, but not biomechanical gait measures, after stroke when compared to Landscape observation with Functional training based on neurodevelopmental techniques.
- Gait training with Rhythmic auditory stimulation and conventional therapy (bobath) may be beneficial for improving biomechanical balance measures, but not biomechanical gait measures and gait speed, after stroke when compared to Gait training with conventional therapy (bobath).
- Cyclic neuromuscular electrical stimulation with Bobath may be beneficial for improving muscle strength, spasticity, and range of motion, but not neurophysiological measures, after stroke when compared to Bobath Approach.
- Body weight supported Treadmill with Bobath physiotherapy may be beneficial for improving gait speed and gait endurance, but not motor recovery and functional mobility, after stroke when compared to Bobath physiotherapy.
- Musical motor feedback with Conventional gait therapy and Neurodevelopmental therapy may not be beneficial for improving gait speed after stroke when compared to Conventional gait therapy with Neurodevelopmental therapy; the literature is mixed regarding biomechanical gait measures.
- Motor relearning with electromyography biofeedback may not be beneficial for improving range of motion, neurophysiological measures, and gait speed after stroke when compared to Motor relearning.

Summary of Key Points: Neurodevelopmental Techniques and Motor Relearning



Intervention	Control(s)	Function domain(s)	Effect
Bobath Concept Approach	Conventional Therapies	Spasticity, activities of daily living, balance, quality of life	+
Bobath Concept Approach	Conventional Therapies	Motor recovery, biomechanical gait measures	–
Bobath Concept Approach	Conventional Therapies	Gait speed, functional mobility	=
Early Bobath Approaches	Late Bobath Approaches	Functional mobility, balance	+
Bobath Concept Approach with Task-Specific Training	Task-Specific Training	Gait speed	+
Bobath Concept Approach with Task-Specific Training	Task-Specific Training	Biomechanical balance measures, activities of daily living, gait endurance, balance	–

Motor Relearning Programmes	Conventional Therapy or Sham	Biomechanical balance measures, activities of daily living, balance	+
Motor Relearning Programmes	Conventional Therapy or Sham	Functional mobility	–
Motor relearning with lower limb force-feedback	Motor relearning with upper limb force-feedback	Gait speed, gait endurance	+
Motor relearning with lower limb force-feedback	Motor relearning with upper limb force-feedback	Motor recovery, functional mobility	–
Motor Relearning	Bobath Concept Approach	Motor recovery, spasticity, sensory and proprioceptive function, activities of daily living, gait endurance, functional mobility, quality of life	–
Neurodevelopmental Bobath Concept Approach	proprioceptive neuromuscular facilitation method (proprioceptive neuromuscular facilitation)	Biomechanical gait measures	+
Bobath Concept Approach Combined with Other Therapies	Bobath or Conventional Therapy	Range of motion, balance	+
Bobath Concept Approach Combined with Other Therapies	Bobath or Conventional Therapy	Functional mobility	–
Bobath Concept Approach	Task-Specific Training	Biomechanical gait measures, biomechanical balance measures, muscle strength, activities of daily living, gait speed, functional mobility, balance	–
Functional (adaptive) movement approach	functional approach for lower limb dressing	Motor recovery, activities of daily living	–
Gaze stabilization exercises with balance exercises and neurodevelopmental treatment	Balance exercises with neurodevelopmental treatment	Biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility	+
Gaze stabilization exercises with balance exercises and neurodevelopmental treatment	Balance exercises with neurodevelopmental treatment	Balance, falls and fear of falling	–
Gaze stabilization exercises with balance exercises and neurodevelopmental treatment	gaze stabilization exercises with neurodevelopmental treatment	Biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility	+
Gaze stabilization exercises with balance exercises and neurodevelopmental treatment	gaze stabilization exercises with neurodevelopmental treatment	Balance, falls and fear of falling	–
Cervical mobilization with Bobath neurodevelopmental therapy	Sham spinal mobilization with Bobath neurodevelopmental therapy	Biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility	+
Sustained natural apophyseal glides with neurodevelopmental techniques	Maitland mobilization with neurodevelopmental techniques	Biomechanical balance measures, gait speed, gait endurance, functional mobility, balance	–
Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Range of motion	+
Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent	Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent	Balance	–

pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)		
Sensory training with Trunk-centred Bobath exercise	Trunk-centred Bobath exercise	Sensory and proprioceptive function	+
Sensory training with Trunk-centred Bobath exercise	Trunk-centred Bobath exercise	Activities of daily living, gait endurance, balance	−
Motor Relearning Program with Obstacle walking	Motor Relearning Program	Spasticity, functional mobility	+
Whole body vibration with Neurodevelopmental treatment	Neurodevelopmental treatment	Gait endurance	+
Whole body vibration with Neurodevelopmental treatment	Neurodevelopmental treatment	Neurophysiological measures, aerobic measures	−
Repetitive transcranial magnetic stimulation with Motor relearning procedure	Motor relearning procedure with Conventional rehabilitation	Motor recovery, spasticity, neurophysiological measures	+
Repetitive transcranial magnetic stimulation with Motor relearning procedure	Motor relearning procedure with Conventional rehabilitation	Functional mobility	−
Dry needling with Neurodevelopmental therapy	Neurodevelopmental therapy	Range of motion, gait speed, balance	+
Dry needling with Neurodevelopmental therapy	Neurodevelopmental therapy	Spasticity	=
Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques	Talocrural joint only mobilization with neurodevelopmental techniques	Muscle strength, gait speed, functional mobility, balance	+
Inspiratory Muscle Training with Neurodevelopmental Bobath Treatment	Neurodevelopmental Bobath Treatment	Aerobic measures, gait endurance, functional mobility	−
Inspiratory Muscle Training with Neurodevelopmental Bobath Treatment	Neurodevelopmental Bobath Treatment	Balance	=
Muscle strengthening training to non-paralytic dorsiflexion muscles with neurodevelopmental therapy	Muscle strengthening training to paralytic dorsiflexion muscles with neurodevelopmental therapy	Neurophysiological measures, gait speed, functional mobility	−
Matrix Rhythm Therapy (vibration) from thoracic spine to lower extremity with Bobath Therapy	Bobath Therapy	Spasticity, range of motion, gait speed, functional mobility, balance	+
Matrix Rhythm Therapy (vibration) from thoracic spine to lower extremity with Bobath Therapy	Bobath Therapy	Biomechanical gait measures	−
Segmental mid-thoracic mobilization with neurodevelopmental therapy	Foam roller exercises with neurodevelopmental therapy	Quality of life	+
Segmental mid-thoracic mobilization with neurodevelopmental therapy	Foam roller exercises with neurodevelopmental therapy	Biomechanical balance measures, aerobic measures	−
Modified constraint-induced movement therapy with Neurodevelopmental therapy	neurodevelopmental therapy	Muscle strength	+
Modified constraint-induced movement therapy with Neurodevelopmental therapy	neurodevelopmental therapy	Quality of life	−
Bobath with dry needling	Bobath	Motor recovery, biomechanical balance measures, spasticity	+

Action observation of community ambulation with Functional training based on neurodevelopmental techniques	Landscape observation with Functional training based on neurodevelopmental techniques	Gait speed, functional mobility, falls and fear of falling	+
Action observation of community ambulation with Functional training based on neurodevelopmental techniques	Landscape observation with Functional training based on neurodevelopmental techniques	Biomechanical gait measures	–
Gait training with Rhythmic auditory stimulation and conventional therapy (bobath)	Gait training with conventional therapy (bobath)	Biomechanical balance measures	+
Gait training with Rhythmic auditory stimulation and conventional therapy (bobath)	Gait training with conventional therapy (bobath)	Biomechanical gait measures, gait speed	–
Cyclic neuromuscular electrical stimulation with Bobath	Bobath Approach	Muscle strength, spasticity, range of motion	+
Cyclic neuromuscular electrical stimulation with Bobath	Bobath Approach	Neurophysiological measures	–
Body weight supported Treadmill with Bobath physiotherapy	Bobath physiotherapy	Gait speed, gait endurance	+
Body weight supported Treadmill with Bobath physiotherapy	Bobath physiotherapy	Motor recovery, functional mobility	–
Musical motor feedback with Conventional gait therapy and Neurodevelopmental therapy	Conventional gait therapy with Neurodevelopmental therapy	Gait speed	–
Musical motor feedback with Conventional gait therapy and Neurodevelopmental therapy	Conventional gait therapy with Neurodevelopmental therapy	Biomechanical gait measures	=
Motor relearning with electromyography biofeedback	Motor relearning	Range of motion, neurophysiological measures, gait speed	–

Sit-to-Stand Training

Adopted from: https://unsplash.com/

Standing from a seated position is considered the most frequently performed functional task and is necessary for mobility (Alexander et al., 2000). Sit-to-stand training is a targeted and specific intervention aimed at improving this particular movement, as well as at improving balance and muscle strength (Tung et al. 2010). Sit-to-stand training may improve outcomes through restoration of impairment, compensation for impairment, or substitution for impairment (Pollock et al., 2014).

Sit-to-stand training can be modified through providing an unstable support surface or through adjusting the positioning of the nonparetic limb to an asymmetric position, which can improve the weight-bearing rate of the paretic limb when compared to the symmetric foot position (Laufer et al., 2000).

A total of fifteen RCTs were found that evaluated Sit-to-Stand training for lower extremity motor rehabilitation. Four RCTs compared Sit-to-Stand Training with Conventional Therapy (Amala et al. 2024; Logan et al. 2022; Kerr et al. 2017; Tung et al. 2010). One RCT evaluated Sit-to-Stand Training with Various Tools (Rasheeda & Sivakumar 2017). One RCT compared Unstable Sit-to-Stand Support Surface with Stable Sit-to-Stand Support Surface (Mun et al. 2014). Two RCTs compared Sit-to-stand Training with Asymmetrical Foot Position with Sit-to-stand Training with Symmetrical Foot Position (Liu et al. 2016b; Farqalit et al. 2013). One RCT evaluated Sit-to-Stand training with Auditory Feedback (Engardt et al. 1993). Two RCTs evaluated Sit-to-Stand training with Visual Feedback (Hyun et al. 2021; Britton et al. 2008). One RCT compared Modified Sit-to-Stand Training with Conventional Therapy (Suchetha et al. 2018). One RCT evaluated Sit-to-Stand training combined with postural control biofeedback (Cheng et al. 2001). One RCT compared Sit-to-Stand training combined with TENS with Sit-to-Stand Training (Jung et al. 2017b). One RCT compared Intensive Sit-to-Stand Training with Regular Sit-to-Stand Training (DeSousa et al. 2019). One RCT compared Lateral Weight Transference Exercises in Sitting and Standing with Conventional Care (Howe et al. 2005).

In addition, one RCT in which Sit-to-Stand training formed part of a combined or comparative intervention are cross-referenced at the end of Table 2; their primary listings appear in other tables.

The methodological details and results of all fifteen RCTs are presented in Table 2.

Table 2. RCTs Evaluating Sit-to-Stand Training for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Sit-to-Stand Training vs Conventional Therapy		
Amala et al. (2024) RCT (4) Nstart=66 Nend=66 TPS=Subacute A vs 0	E: Sit-to-stand training + Conventional physiotherapy C: Conventional physiotherapy Duration: 45 mins/d, 5d	E vs C: Berg balance scale (+exp) Barthel Index (+exp) Muscle strength Hip flexers (+exp) Hip extensors (+exp) knee flexors (+exp) knee extensors (+exp)
Logan et al. (2022) RCT (2) Nstart=45 Nend=40 TPS=Acute A + B vs 0	E: Sit-to-Stand training + Standing practice + Conventional therapy C: Conventional therapy Duration: 45min/d, 5-7d/wk, for 3wks	E vs C: Barthel Scale (No stats) Trunk control test (No stats) Visual analog fatigue scale (No stats) Patient Health Questionnaire-9 (No stats) Knee extensor muscle strength (No stats) Modified Ashworth Scale (No stats) stroke Aphasia Depression Questionnaire-10 (No stats) EQ-5D 5L (No stats)
Kerr et al. (2017) RCT (6) Nstart=61 Nend=59 TPS=Acute A vs 0	E: Sit-to-Stand movements performed (Count by using a physical activity monitor) + Conventional therapy C: Conventional rehabilitation Duration: 2wks	E vs C: Modified Rivermead Mobility Index (-) Five tim e Sit-to-stand (-)
Tung et al. (2010) RCT (6) Nstart=32 Nend=32	E: Sit-to-Stand training + Physical therapy C: Physical therapy Duration: E: 30min/d, 3d/wk, 4wks general therapy + 15min/d, 3d/wk, 4wks	E vs C: Static balance-weight distribution (-) Limit of stability Max excursion Anterior (-)

Sit-to-Stand Training with Various Tools		
Rasheeda & Sivakumar (2017) RCT (7) Nstart=74 Nend=67 TPS=Acute A1 vs A2	E: Sit-to-Stand Training (with Swiss ball) C: Sit-to-stand Training (with stool) Duration: 40min/d for 10 days	E vs C: 30-Second Sit-to-stand Test (-) Weight Bearing (+exp) Brunnstrom Recovery Stage (+exp)
Unstable Sit-to-Stand Support Surface vs Stable Sit-to-Stand Support Surface		
Mun et al. (2014) RCT (3) Nstart=30 Nend=19 TPS=Chronic A vs B	E: Unstable support surface sit- to-stand training C: Stable support surface sit-to- stand training Duration: 30min/d, 3d/wk, for 4wks	E vs C: Step length (+exp) Berg Balance Scale (-) Timed Up-and-Go Test (-) 10-Meter Walk Test (-) 6-Minute Walk Test (-)
Sit-to-stand Training with Asymmetrical Foot Position vs Sit-to-stand Training with Symmetrical Foot Position		
Liu et al. (2016b) RCT (7) Nstart=50 Nend=50 TPS=Subacute A vs B	E: Sit-to-stand with asymmetrical foot positioning (paretic foot placed posterior) C: Sit-to-stand training with symmetrical foot position Duration: 30min/d, 5d/wk, for 4wks	E vs C: Berg Balance Scale (+exp) Sit-to-stand (+exp) Static balance (+exp) Dynamic balance (+exp)
Fargalit et al. (2013) RCT (8) Nstart=40 Nend=40 TPS=Chronic A1 vs A2	E: Sit-to-stand training with asymmetrical foot position + conventional care C: Sit-to-stand training with symmetrical foot position + conventional care Duration: 30min/d, 5d/wk for 4wk	E vs C: Berg Balance Scale (+exp) Timed Up-and-Go Test (+exp) Sit-to-stand repetitions (+exp)
Sit-to-Stand training with Auditory Feedback		
Engardt et al. (1993) RCT (5) Nstart=42 Nend=40 TPS=Subacute A vs B Also in Table 15 (Biofeedback)	E: Continuous Auditory Feedback During Sit-to-Stand Training C: No Feedback During Sit-to- stand Training Duration: 45min/d, 5d/wk, 6wks	E vs C: Weight distribution (+exp) Motor Assessment Scale (+exp) Barthel Index (-) Fugl-Meyer Assessment (+exp)

Sit-to-Stand training with Visual Feedback		
Britton et al. (2008) RCT (5) Nstart=18 Nend=13 TPS=Subacute A + B vs C Also in Table 15 (Biofeedback)	E: Usual rehabilitation + Sit-to- Stand training + visual feedback C: Usual rehabilitation + Arm task training Duration: 30min/d, 5d/wk, 3wks	E vs C: Frequency of sit-to-stands/day (-) Mean time to rise (-) Weight bearing -affected leg (+exp) Number of attempts to successfully stand three times (-) Sit to stand 1-min test (-)
Modified Sit-to-Stand Training vs Conventional Therapy		
Suchetha et al. (2018) RCT (5) Nstart=30 Nend=28 TPS=Subacute A vs 0 Also in Table 17 (Mental Practice)	E: Modified sit-to-stand training with mental practice + conventional therapy C: Conventional Treatment Duration: 1h/d, 5d/wk, 2wks	E vs C: Berg Balance Scale (+exp) Dynamic Gait Index (+exp)
Sit-to-Stand training combined with postural control biofeedback		
Cheng et al. (2001) RCT (5) Nstart=54 Nend=54 TPS=Subacute A + B vs 0 Also in Table 15 (Biofeedback)	E: Standing postural symmetry training with a visual and auditory biofeedback trainer + repetitive sit-to-stand training+ conventional rehabilitation C: Conventional rehabilitation Duration: 30min/d postural training & 20min/d sit-to-stand training, 5d/wk for 3wks	E vs C: Rate of falls (No stats) the anteroposterior COP (No stats) mediolateral COP (No stats) Rate of rise in force during rising from a chair (No stats) time needed to rise and sit (No stats)
Sit-to-Stand training combined with TENS vs Sit-to-Stand Training		
Jung et al. (2017b) RCT (7) Nstart=41 Nend=40 TPS=Chronic A + B vs A Also in Table 30 (Transcutaneous Electrical Nerve Stimulation (TENS))	E: Sit-to-stand training + TENS + conventional therapy C: Sit-to-stand training + sham TENS + conventional therapy Duration: 15min/d, 5d/wk, 6wks sit-to-stand training & 30min/d, 5d/wk, 6wks TENS or sham 60min/d, 5d/wk, 6wks conventional physiotherapy	E vs C: Postural sway distance (cm) Eyes open (+exp) Eyes closed (+exp) Muscle strength (kg) Hip extensor (+exp) Knee extensor (-) Ankle plantar flexor (-) CSS score (Spasticity) (+exp)
Intensive Sit-to-Stand Training vs Regular Sit-to-Stand Training		
DeSousa et al. (2019) RCT (8) Nstart=30 Nend=30 TPS=Acute A vs B	E: Intensive Sit-To-Stand Training C: Usual Sit-to-Stand Training Duration: 2h/d, 5d/wk, 2wks usual sit-to-stand training; 3hr/d on weekdays + 2hr/d on weekends, 2wks intensive training.	E vs C: Global Impressions of sit-to-stand Change (+exp) Mobility Scale for Acute Stroke Patients – sit-to- stand item (-) Manual Muscle Test: Lower Limb Extensor Strength (-) Gross Lower Limb Extension Strength (+exp) Goal Attainment Scale (-) Change in ability to move from sitting to standing (+exp)
Lateral Weight Transference Exercises in Sitting and Standing VS Conventional Care		
Howe et al. (2005) RCT (7)	E: Lateral weight transference exercises in sitting and standing + Conventional care	E vs C: Lateral Reach Test (-)

Nstart=35 Nend=33 TPS=Acute A vs 0	C: Conventional care Duration: 30min/d, 3d/wk for 4wks	Static Standing Balance (-) Sit-to-Stand-to-Sit (-)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Hyun et al. (2021) RCT (5) Nstart=40 Nend=30 TPS=Subacute A + B vs A Primary listing: Table 15 (Biofeedback)	E: Sit-to-stand training + visual feedback with Wii Balance Board + Standard physiotherapy C: Sit-to-stand Training + Standard physiotherapy Duration: 20min/d, 5d/wk, 6 wks sit-to-stand training & 30min/d, 5d/wk, 6wks physiotherapy	E vs C: Manual muscle Strength test of the Lower Extremities Hip flexor (+exp) hip abductor (+exp) knee extensor (+exp) Centre of Pressure (+exp) Berg Balance Scale (+exp) 10 meter walking test (+exp) Timed Up and Go test (+exp) Stroke-Specific Quality of Life (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Sit-to-Stand Training may not have a difference in efficacy when compared to Conventional Therapy for improving fatigue and sleep.	1	Logan et al. 2022

Key Points

- Sit-to-Stand Training may be beneficial for improving muscle strength, but not biomechanical balance measures, spasticity, functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy; the literature is mixed regarding activities of daily living.

- Sit-to-Stand Training (with Swiss ball) may be beneficial for improving motor recovery and biomechanical balance measures, but not functional mobility, after stroke when compared to Sit-to-stand Training (with stool).
- Unstable Sit-to-Stand Support Surface may be beneficial for improving biomechanical gait measures, but not gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Stable Sit-to-Stand Support Surface.
- Sit-to-stand Training with Asymmetrical Foot Position may be beneficial for improving functional mobility and balance after stroke when compared to Sit-to-stand Training with Symmetrical Foot Position.
- Continuous Auditory Feedback During Sit-to-Stand Training may be beneficial for improving motor recovery, biomechanical balance measures, and functional mobility, but not activities of daily living, after stroke when compared to No Feedback During Sit-to- stand Training.
- Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy may be beneficial for improving muscle strength, gait speed, functional mobility, balance, and quality of life after stroke when compared to Sit to Stand Training with physiotherapy.
- Sit-to-Stand training with Visual Feedback may not be beneficial for improving functional mobility after stroke when compared to Sit-to-stand Training with physiotherapy; the literature is mixed regarding biomechanical balance measures.
- Modified Sit-to-Stand Training may be beneficial for improving functional mobility and balance after stroke when compared to Conventional Therapy.
- Standing postural symmetry training with a visual and auditory biofeedback trainer with repetitive sit-to-stand training and conventional rehabilitation may not be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Conventional rehabilitation.
- Sit-to-Stand training combined with transcutaneous electrical nerve stimulation may be beneficial for improving biomechanical balance measures and spasticity, but not muscle strength, after stroke when compared to Sit-to-Stand Training.
- Intensive Sit-to-Stand Training may be beneficial for improving functional mobility, but not activities of daily living, after stroke when compared to Regular Sit-to-Stand Training; the literature is mixed regarding muscle strength.
- Lateral Weight Transference Exercises in Sitting and Standing may not be beneficial for improving functional mobility and balance after stroke when compared to Conventional Care.

Summary of Key Points: Sit-to-Stand Training

Intervention	Control(s)	Function domain(s)	Effect
Sit-to-Stand Training	Conventional Therapy	Muscle strength	+
Sit-to-Stand Training	Conventional Therapy	Biomechanical balance measures, spasticity, functional mobility, balance, quality of life	–
Sit-to-Stand Training	Conventional Therapy	Activities of daily living	=
Sit-to-Stand Training (with Swiss ball)	Sit-to-stand Training (with stool)	Motor recovery, biomechanical balance measures	+
Sit-to-Stand Training (with Swiss ball)	Sit-to-stand Training (with stool)	Functional mobility	–
Unstable Sit-to-Stand Support Surface	Stable Sit-to-Stand Support Surface	Biomechanical gait measures	+
Unstable Sit-to-Stand Support Surface	Stable Sit-to-Stand Support Surface	Gait speed, gait endurance, functional mobility, balance	–
Sit-to-stand Training with Asymmetrical Foot Position	Sit-to-stand Training with Symmetrical Foot Position	Functional mobility, balance	+
Continuous Auditory Feedback During Sit-to-Stand Training	No Feedback During Sit-to- stand Training	Motor recovery, biomechanical balance measures, functional mobility	+

Continuous Auditory Feedback During Sit-to-Stand Training	No Feedback During Sit-to- stand Training	Activities of daily living	–
Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy	Sit to Stand Training with physiotherapy	Muscle strength, gait speed, functional mobility, balance, quality of life	+
Sit-to-Stand training with Visual Feedback	Sit-to-stand Training with physiotherapy	Functional mobility	–
Sit-to-Stand training with Visual Feedback	Sit-to-stand Training with physiotherapy	Biomechanical balance measures	=
Modified Sit-to-Stand Training	Conventional Therapy	Functional mobility, balance	+
Standing postural symmetry training with a visual and auditory biofeedback trainer with repetitive sit-to-stand training and conventional rehabilitation	Conventional rehabilitation	Biomechanical balance measures, falls and fear of falling	–
Sit-to-Stand training combined with transcutaneous electrical nerve stimulation	Sit-to-Stand Training	Biomechanical balance measures, spasticity	+
Sit-to-Stand training combined with transcutaneous electrical nerve stimulation	Sit-to-Stand Training	Muscle strength	–
Intensive Sit-to-Stand Training	Regular Sit-to-Stand Training	Functional mobility	+
Intensive Sit-to-Stand Training	Regular Sit-to-Stand Training	Activities of daily living	–
Intensive Sit-to-Stand Training	Regular Sit-to-Stand Training	Muscle strength	=
Lateral Weight Transference Exercises in Sitting and Standing	Conventional Care	Functional mobility, balance	–

Wheelchair Use

Adopted from http://www.neater.co.uk/neater-uni-chair/

Following stroke, particularly when associated with hemiplegia, individuals often require use of a wheelchair. Wheelchairs are usually self-propelling, but can also be manually propelled (Blower, 1988). The Neater Uni-Chair is

a wheelchair designed for those with hemiplegia and thus only requires one hand to propel and one foot to steer (Mandy et al., 2014). While patients view the temporary use of a wheelchair positively, there is a lack of consensus between clinicians about the benefits of wheelchair use in stroke rehabilitation, particularly in the acute phase (Ashburn & Lynch, 1988; Engstrom, 1995).

The main advantage for early use of wheelchairs is related to support for the hemiplegic sides and greater functional improvement and independence. The popular treatment regimen described by Bobath discourages early self-propulsion in a wheelchair because it is believed to cause poor posture and increased tone on the hemiplegic side, and may have an adverse impact on long- term recovery (Ashburn & Lynch, 1988; Bobath, 1990). These postulated negative impacts include increasing spasticity, encouraging one-sidedness, and reducing motivation to walk (Blower, 1988). While the use of wheelchairs following stroke is widespread, there is limited research evaluating them as an intervention.

A total of two RCTs were found that evaluated wheelchair use for lower extremity motor rehabilitation. One RCT compared Neater Uni-Wheelchair Attachment with Standard Wheelchair (Mandy et al. 2015). One RCT compared Encouraging Self-Propulsion with Discouraging Self-Propulsion (Barrett et al. 2001).

The methodological details and results of all two RCTs are presented in Table 3.

Table 3. RCTs Evaluating Wheelchair Use for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Neater Uni-Wheelchair Attachment vs Standard Wheelchair		
Mandy et al. (2015) RCT crossover (4) Nstart=4 Nend=4 TPS=Not reported A vs B	E: Neater Uni-wheelchair attachment C: Standard wheelchair Duration: Completion of tasks in each chair - 10min rest in between	E vs C: Motor Skills (+exp) Process Skills (-) ADLs Swedish table laying activity (-) Bed making activity (+exp)
Encouraging vs Discouraging Self-Propulsion		
Barrett et al. (2001) RCT (7) Nstart=40 Nend=35 TPS=Acute A vs B	E: Encouraged to self-propelusion C: Discouraged from self- propulsion Duration: 8 wks	E vs C: Barthel index (-) Nottingham extended activities of daily life (-) General health questionnaire 12 (-) Modified ashworth scale (-) 10-metre walk test (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Encouraging Self-Propulsion may not have a difference in efficacy when compared to Discouraging Self-Propulsion for improving spasticity.	1	Barrett et al. 2001

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	There is conflicting evidence about the effect of Neater Uni-Wheelchair Attachment when compared to Wheelchair for improving activities of daily living.	1	Mandy et al. 2015
1b	Encouraging Self-Propulsion may not have a difference in efficacy when compared to Discouraging Self-Propulsion for improving activities of daily living.	1	Barrett et al. 2001

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Encouraging Self-Propulsion may not have a difference in efficacy when compared to Discouraging Self-Propulsion for improving gait speed.	1	Barrett et al. 2001

Key Points

- The literature is mixed regarding the effect of Neater Uni-Wheelchair Attachment on activities of daily living after stroke when compared to Wheelchair.
- Encouraging Self-Propulsion may not be beneficial for improving spasticity, activities of daily living, and gait speed after stroke when compared to Discouraging Self-Propulsion.

Summary of Key Points: Wheelchair Use

Intervention	Control(s)	Function domain(s)	Effect
Neater Uni-Wheelchair Attachment	Wheelchair	Activities of daily living	=
Encouraging Self-Propulsion	Discouraging Self-Propulsion	Spasticity, activities of daily living, gait speed	–

Trunk Training

Adopted from https://www.flintrehab.com/2016/core-exercises-for-stroke-patients/

Trunk impairment is common after stroke and is directly associated with balance and gait (Jijimol et al., 2013; Verheyden et al., 2006). Additionally, trunk control and balance while sitting are well known predictors in functional outcome and hospital stay after a stroke (Franchignoni et al., 1997; Verheyden et al., 2006).

Trunk training targets the trunk or “core muscles”, which include those supporting the lumbo- pelvic-hip complex (Hibbs et al., 2008). An example of a specific trunk stabilization method is the abdominal drawing-in maneuver, which involves selectively activating the transversus abdominis (Hides et al., 2006). Core stability training typically involves a combination of multiple exercises that encourage deep muscle movement and selective pelvic exercises to produce a comprehensive core stabilization rehabilitation program (Haruyama et al. 2017).

A total of 49 RCTs were found that evaluated trunk training for lower extremity motor rehabilitation. Sixteen RCTs compared Trunk Training with Conventional Therapy (Almasoudi et al. 2024; Kaymaz et al. 2024; Aycicek et al. 2024; Nadeem et al. 2024; El Bahrawy et al. 2024; Mahmood et al. 2022; Kim et al. 2022b; Park et al. 2019b; Dubey et al. 2018; Haruyama et al. 2017; Büyükavci et al. 2016; Cabanas-Valdes et al. 2016; Jung et al. 2014; Chung et al. 2013; Saeys et al. 2012; Verheyden et al. 2009). Three RCTs evaluated Trunk Training with Physio Equipment (Choi et al. 2021a; Choi et al. 2020a; Cho et al. 2019). Four RCTs compared Trunk Training with Tilted Platforms with Trunk Training with Horizontal Platforms (Sawa et al. 2024; Sawa et al. 2022; Fukata et al. 2021; Fujino et al. 2016). Eight RCTs compared Trunk Exercise with Unstable Surface with Trunk Exercise with Stable Surface or conventional therapy (Karthikbabu et al. 2022; Khurana et al. 2022; Lee et al. 2020d; Sarwar et al. 2019; Tirupatamma et al. 2019; Karthikbabu et al. 2018; Lim et al. 2012; Karthikbabu et al. 2011). Three RCTs compared Trunk Training Combined with Robotics with Conventional Therapy (Kim et al. 2022f; Min et al. 2020; Moon et al. 2017). One RCT compared Trunk Training Combined with Dual-Task Training with Trunk Training (Ahmed et al. 2021). One RCT compared Trunk Training with Cognitive Training (Van Criekinge et al. 2020). Two RCTs compared Dynamic Neuromuscular Stabilization with Conventional Core Exercises (Yoon et al., 2020; Lee et al. 2018c). Five RCTs compared Trunk Training with Visual or Auditory Feedback with Conventional Therapy (Kim et al. 2023; Shin et al. 2020; Jung et al. 2017a; Shin & Song 2016; De Seze et al. 2001). One RCT compared Trunk Training with Balance Training and TENS with Treadmill Training and Placebo TENS (Lim et al. 2019). Three RCTs evaluated Different Trunk Muscle Activation Exercises Compared to Each other (Younas et al. 2024; Lee et al. 2020d; Muckel et al. 2014). One RCT compared Trunk Training with Delayed with Real-Time Visual Feedback (Inoue et al. 2022a). One RCT compared Kneeling Training with Treadmill Training (Zhang et al. 2024c).

In addition, eleven RCTs in which trunk training formed part of a combined or comparative intervention are cross-referenced at the end of Table 4; their primary listings appear in other tables.

The methodological details and results of all 49 RCTs are presented in Table 4.

Table 4. RCTs Evaluating Trunk Training for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)

(2024) RCT (5) Nstart=27 Nend=23 TPS=Chronic A + B vs B Primary listing: Table 32 (Additional Afferent and Peripheral Stimulation Methods)	E: Sensory training + Trunk-centred Bobath exercise C: Trunk-centred Bobath exercise Duration: 40 mins/d, 3ds/wk, 8wks	E vs C: TIS static sitting balance (-) dynamic sitting balance (-) coordination (-) total (-) Trunk reposition error (+exp) Berg balance scale (-) 2 minute walk test (-) Barthel index (-)
Jung et al. (2021) RCT (7) Nstart=24 Nend=24 TPS=Subacute A vs B Primary listing: Table 11 (Balance Training)	E: Space Balance 3D system for active trunk training + conventional physical and occupational therapy C: General trunk training + Conventional physical and occupational physiotherapy Duration: 30min/d, 5d/wk, for 3wks	E vs C: Trunk Impairment Scale (+exp) Trunk Flexion muscle strength (+exp) Trunk Extension muscle strength (+exp) Static balance (+exp) Brunel Balance Assessment (+exp)
Cho et al. (2020b) RCT (8) Nstart=28 Nend=28 TPS=Chronic A + B vs A Primary listing: Table 13 (Orthotic Devices)	E: Trunk rehabilitation + Kinesio taping C: Trunk rehabilitation + Placebo taping Duration: 18hr/d, 7d/wk, 8wks Taping & 60min/d, 3d/wk, 8wks Trunk rehabilitation	E vs C: Dynamic center of pressure affected-side sway area (-) unaffected-side sway area (-) forward sway area (+exp) backward sway area (-) LOS total area (-) Static sway area (-) Static sway length (-)
Jung et al. (2017a) RCT (6) Nstart=46 Nend=43 TPS=Chronic A + B vs A Primary listing: Table 15 (Biofeedback)	E: Trunk stabilization exercises + audiovisual biofeedback (Pressure biofeedback unit) C: Trunk stabilization exercises Duration: 50min/d, 5d/wk,6wks	E vs C: Thickness of trunk muscles (+exp) TrA-affected (+exp) TrA-unaffected (+exp) IO-affected (-) IO-unaffected (-) EO-affected (+con) EO-unaffected (+con) Symmetric ratio (-) static sitting balance ability (+exp) dynamic sitting balance ability (+exp)
Shin & Song (2016) RCT (6) Nstart=24 Nend=24 TPS=Chronic A vs 0 Primary listing: Table 15 (Biofeedback)	E: Smartphone visual feedback for trunk control training + Conventional care C: Conventional care Duration: 80min/d conventional care + 20min/d Smartphone therapy, 5d/wk, 4wks	E vs C: Timed Up and Go (+exp) Static balance Eyes closed (+exp) Eyes open (+exp) Trunk Impairment scale (+exp) Modified Functional reach test (+exp)
Park et al. (2016) RCT (5) Nstart=28 Nend=28	E: Aquatic therapy (Halliwick, Watsu, and Trunk Training) C: Trunk control exercises Duration: 30min/d, 3d/wk, 4wks	E vs C: Gait Speed (-) Walking cycle (+con) Affected side stance phase (-)

TPS=Chronic A vs B Primary listing: Table 20 (Aquatic Therapy)		Affected side stride length (+con) Symmetry index of stance phase (-) Symmetry index of stride length (-)
Ko et al. (2016) RCT (6) Nstart=34 Nend=30 TPS=Acute A + B vs A vs B Primary listing: Table 29 (Neuromuscular Electrical Stimulation (NMES))	E1: Trunk NMES + Core muscle training E2: Trunk NMES C: Core Training Duration: 20min/d, 3d/wk, for 3wks	E1 vs C: Trunk Impairment Scale (-) Dynamic Sitting Balance (+exp1) Berg Balance Scale (+exp1) Postural Assessment for Stroke Scale (-) Modified Barthel Index (-) E1 vs E2: Trunk Impairment Scale (-) Dynamic Sitting Balance (-) Berg Balance Scale (+exp1) Postural Assessment for Stroke Scale (-) Modified Barthel Index (-)
Chung et al. (2014) RCT (4) Nstart=26 Nend=19 TPS=Chronic A + B vs A Primary listing: Table 15 (Biofeedback)	E: Core stability exercises + real time feedback + conventional physical therapy C: Core stability exercises + conventional physical therapy Duration: 30min/session, 3d/wk for 6wks	E vs C: Timed Up and Go test (+exp) Gait velocity (+exp) Gait cadence (-) Affected side Stride length (+exp) Step length (-) Single support time (+exp) Double support time (-) Non-affected side Stride length (+exp) Step length (-) Single support time (-) Double support time (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Trunk Training may produce greater improvements in motor recovery than Conventional Therapy.	3	Dubey et al. 2018; Büyükavci et al. 2016; Saeys et al. 2012
1a	Trunk Training with Tilted Platforms may not have a difference in efficacy when compared to Trunk Training with Horizontal Platforms for improving motor recovery.	2	Fukata et al. 2021; Fujino et al. 2016
1b	Trunk Exercise with Unstable Surface may not have a difference in efficacy when compared to Trunk Exercise with Stable Surface or conventional therapy for improving motor recovery.	1	Lee et al. 2020c

1b	Trunk Training Combined with Robotics may produce greater improvements in motor recovery than Conventional Therapy.	1	Min et al. 2020
2	Trunk Training with Delayed may not have a difference in efficacy when compared to Real-Time Visual Feedback for improving motor recovery.	1	Inoue et al. 2022a
1b	Kneeling Training may not have a difference in efficacy when compared to Treadmill Training for improving motor recovery.	1	Zhang et al. 2024c

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Trunk Training may not have a difference in efficacy when compared to Conventional Therapy for improving biomechanical gait measures.	2	Dubey et al. 2018; Chung et al. 2013
1b	Trunk stabilization exercise with Pelvic compression belt on paretic side and comprehensive rehabilitation therapy may produce greater improvements in biomechanical gait measures than Trunk stabilization exercise with Pelvic compression belt on non- paretic side and comprehensive rehabilitation therapy.	1	Choi et al. 2020a
1b	Trunk Training with Physio Equipment may not have a difference in efficacy when compared to Trunk stabilization exercises with conventional physical exercise for improving biomechanical gait measures.	1	Choi et al. 2020a
2	There is conflicting evidence about the effect of Trunk Training Combined with Robotics when compared to Conventional Therapy for improving biomechanical gait measures.	1	Moon et al. 2017
1b	Trunk Training may not have a difference in efficacy when compared to Cognitive Training for improving biomechanical gait measures.	1	Van Criekinge et al. 2020
2	Dynamic Neuromuscular Stabilization may not have a difference in efficacy when compared to Conventional Core Exercises for improving biomechanical gait measures.	1	Yoon et al. 2020
1a	Trunk Training with Visual or Auditory Feedback may produce greater improvements in biomechanical gait measures than Conventional Therapy.	2	Shin et al. 2020; Jung et al. 2017a
1b	Kneeling Training may not have a difference in efficacy when compared to Treadmill Training for improving biomechanical gait measures.	1	Zhang et al. 2024c
1b	Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit) may not have a difference in efficacy when compared to Trunk stabilization exercises for improving biomechanical gait measures.	1	Jung et al. 2017a
2	Aquatic therapy (Halliwick, Watsu, and Trunk Training) may result in lesser improvements in biomechanical gait measures when compared to Trunk control exercises.	1	Park et al. 2016
2	Core stability exercises with real time feedback and conventional physical therapy may not have a difference in efficacy when compared to Core stability exercises with conventional physical therapy for improving biomechanical gait measures.	1	Chung et al. 2014

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Trunk Training may produce greater improvements in biomechanical balance measures than Conventional Therapy.	2	El Bahrawy et al. 2024; Kim et al. 2022b

2	Trunk stabilization exercise using weights with general physiotherapy may produce greater improvements in biomechanical balance measures than Trunk stabilization without weights with general physiotherapy.	1	Kim et al. 2022b
1b	Trunk Training with Physio Equipment may produce greater improvements in biomechanical balance measures than Trunk stabilization exercises with conventional physical exercise.	1	Choi et al. 2021a
1b	Segmental mid-thoracic mobilization with neurodevelopmental therapy may not have a difference in efficacy when compared to Foam roller exercises with neurodevelopmental therapy for improving biomechanical balance measures.	1	Cho et al. 2019
1b	Trunk Exercise with Unstable Surface may produce greater improvements in biomechanical balance measures than Trunk Exercise with Stable Surface or conventional therapy.	2	Karthikbabu et al. 2022; Lim et al. 2012
1b	Core stability training on stable surface may not have a difference in efficacy when compared to Core stability training on unstable surface for improving biomechanical balance measures.	1	Karthikbabu et al. 2022
1b	Core stability training on stable surface may produce greater improvements in biomechanical balance measures than Individualized physiotherapy.	1	Karthikbabu et al. 2022
1b	Trunk Training Combined with Robotics may produce greater improvements in biomechanical balance measures than Conventional Therapy.	1	Kim et al. 2022f
1b	Trunk rehabilitation with Kinesio taping may not have a difference in efficacy when compared to Trunk rehabilitation with Placebo taping for improving biomechanical balance measures.	1	Cho et al. 2020b

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Trunk Training may not have a difference in efficacy when compared to Conventional Therapy for improving muscle strength.	3	Kaymaz et al. 2024; Aycicek et al. 2024; Dubey et al. 2018
1b	Trunk Exercise with Unstable Surface may produce greater improvements in muscle strength than Trunk Exercise with Stable Surface or conventional therapy.	1	Karthikbabu et al. 2022
1b	Core stability training on stable surface may not have a difference in efficacy when compared to Core stability training on unstable surface for improving muscle strength.	1	Karthikbabu et al. 2022
1b	Core stability training on stable surface may produce greater improvements in muscle strength than Individualized physiotherapy.	1	Karthikbabu et al. 2022
2	Trunk Training Combined with Robotics may produce greater improvements in muscle strength than Conventional Therapy.	1	Moon et al. 2017
2	There is conflicting evidence about the effect of Dynamic Neuromuscular Stabilization when compared to Conventional Core Exercises for improving muscle strength.	1	Yoon et al. 2020
1a	There is conflicting evidence about the effect of Trunk Training with Visual or Auditory Feedback when compared to Conventional Therapy for improving muscle strength.	2	Jung et al. 2017a; De Seze et al. 2001
2	Core muscle training with Functional electrical stimulation may produce greater improvements in muscle strength than Core muscle training.	1	Li et al. 2024c
1b	Space Balance 3D system for active trunk training with conventional physical and occupational therapy may produce greater	1	Jung et al. 2021

	improvements in muscle strength than General trunk training with Conventional physical and occupational physiotherapy.		
1b	There is conflicting evidence about the effect of Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit) when compared to Trunk stabilization exercises for improving muscle strength.	1	Jung et al. 2017a

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Trunk Training with Visual or Auditory Feedback may not have a difference in efficacy when compared to Conventional Therapy for improving spasticity.	1	De Seze et al. 2001

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Trunk Training may not have a difference in efficacy when compared to Conventional Therapy for improving range of motion.	2	Mahmood et al. 2022; Haruyama et al. 2017
2	Dynamic Neuromuscular Stabilization may produce greater improvements in range of motion than Conventional Core Exercises.	1	Lee et al. 2018c
1b	Kneeling Training may not have a difference in efficacy when compared to Treadmill Training for improving range of motion.	1	Zhang et al. 2024c

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Different Trunk Muscle Activation Exercises Compared to Each other when compared to Bobath based trunk training with Conventional therapy for improving neurophysiological measures.	1	Muckel et al. 2014
2	Trunk Training with Delayed may not have a difference in efficacy when compared to Real-Time Visual Feedback for improving neurophysiological measures.	1	Inoue et al. 2022a

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Segmental mid-thoracic mobilization with neurodevelopmental therapy may not have a difference in efficacy when compared to Foam roller exercises with neurodevelopmental therapy for improving aerobic measures.	1	Cho et al. 2019

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Trunk Training with Tilted Platforms may produce greater improvements in sensory and proprioceptive function than Trunk Training with Horizontal Platforms.	3	Sawa et al. 2024; Sawa et al. 2022; Fukata et al. 2021
1b	Trunk Exercise with Unstable Surface may not have a difference in efficacy when compared to Trunk Exercise with Stable Surface or conventional therapy for improving sensory and proprioceptive function.	1	Lee et al. 2020c
1b	Trunk Training with Balance Training and transcutaneous electrical nerve stimulation may produce greater improvements in sensory and	1	Lim et al. 2019

	proprioceptive function than Treadmill Training and Placebo transcutaneous electrical nerve stimulation.		
2	Sensory training with Trunk-centred Bobath exercise may produce greater improvements in sensory and proprioceptive function than Trunk-centred Bobath exercise.	1	Karaca et al. 2024

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Trunk Training may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	7	Almasoudi et al. 2024; Kaymaz et al. 2024; Aycicek et al. 2024; Park et al. 2019b; Dubey et al. 2018; Büyükavci et al. 2016; Cabanas-Valdes et al. 2016
1a	Trunk Training with Tilted Platforms may produce greater improvements in activities of daily living than Trunk Training with Horizontal Platforms.	2	Sawa et al. 2022; Fukata et al. 2021
1b	Stable trunk training with plinth may not have a difference in efficacy when compared to Unstable trunk training with Swiss ball for improving activities of daily living.	1	Karthikbabu et al. 2018
1b	Stable trunk training with plinth or Unstable trunk training with Swiss ball may produce greater improvements in activities of daily living than Standard physiotherapy.	1	Karthikbabu et al. 2018
1b	Trunk Training with Visual or Auditory Feedback may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	1	De Seze et al. 2001
2	Trunk Training with Delayed may not have a difference in efficacy when compared to Real-Time Visual Feedback for improving activities of daily living.	1	Inoue et al. 2022a
2	Sensory training with Trunk-centred Bobath exercise may not have a difference in efficacy when compared to Trunk-centred Bobath exercise for improving activities of daily living.	1	Karaca et al. 2024
1b	Trunk neuromuscular electrical stimulation with Core muscle training may not have a difference in efficacy when compared to Core Training for improving activities of daily living.	1	Ko et al. 2016
1b	Trunk neuromuscular electrical stimulation with Core muscle training may not have a difference in efficacy when compared to Trunk neuromuscular electrical stimulation for improving activities of daily living.	1	Ko et al. 2016

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Trunk Training may produce greater improvements in gait speed than Conventional Therapy.	3	Kim et al. 2022b; Dubey et al. 2018; Chung et al. 2013
2	Trunk stabilization exercise using weights with general physiotherapy may produce greater improvements in gait speed than Trunk stabilization without weights with general physiotherapy.	1	Kim et al. 2022b
1b	Trunk stabilization exercise with Pelvic compression belt on paretic side and comprehensive rehabilitation therapy may produce greater improvements in gait speed than Trunk stabilization exercise with Pelvic compression belt on non- paretic side and comprehensive rehabilitation therapy.	1	Choi et al. 2020a

1b	Trunk Training with Physio Equipment may not have a difference in efficacy when compared to Trunk stabilization exercises with conventional physical exercise for improving gait speed.	1	Choi et al. 2020a
1b	Trunk Exercise with Unstable Surface may produce greater improvements in gait speed than Trunk Exercise with Stable Surface or conventional therapy.	2	Lee et al. 2020c; Lim et al. 2012
1b	Stable trunk training with plinth may not have a difference in efficacy when compared to Unstable trunk training with Swiss ball for improving gait speed.	1	Karthikbabu et al. 2018
1b	Stable trunk training with plinth or Unstable trunk training with Swiss ball may produce greater improvements in gait speed than Standard physiotherapy.	1	Karthikbabu et al. 2018
1b	Trunk Training Combined with Dual-Task Training may produce greater improvements in gait speed than Trunk Training.	1	Ahmed et al. 2021
1b	Trunk Training may produce greater improvements in gait speed than Cognitive Training.	1	Van Criekinge et al. 2020
1a	Trunk Training with Visual or Auditory Feedback may produce greater improvements in gait speed than Conventional Therapy.	2	Kim et al. 2023; Shin et al. 2020
1b	Trunk stabilization exercise with abdominal hallowing with Conventional rehabilitation program may not have a difference in efficacy when compared to Trunk stabilization exercise with bracing maneuver with Conventional rehabilitation program for improving gait speed.	1	Lee et al. 2020d
2	Trunk Training with Delayed may not have a difference in efficacy when compared to Real-Time Visual Feedback for improving gait speed.	1	Inoue et al. 2022a
2	Core muscle training with Functional electrical stimulation may produce greater improvements in gait speed than Core muscle training.	1	Li et al. 2024c
2	Aquatic therapy (Halliwick, Watsu, and Trunk Training) may not have a difference in efficacy when compared to Trunk control exercises for improving gait speed.	1	Park et al. 2016
2	Core stability exercises with real time feedback and conventional physical therapy may produce greater improvements in gait speed than Core stability exercises with conventional physical therapy.	1	Chung et al. 2014

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Trunk Training may not have a difference in efficacy when compared to Conventional Therapy for improving gait endurance.	1	Aycicek et al. 2024
1b	Trunk stabilization exercise with Pelvic compression belt on paretic side and comprehensive rehabilitation therapy may produce greater improvements in gait endurance than Trunk stabilization exercise with Pelvic compression belt on non- paretic side and comprehensive rehabilitation therapy.	1	Choi et al. 2020a
1b	Trunk Training with Physio Equipment may produce greater improvements in gait endurance than Trunk stabilization exercises with conventional physical exercise.	1	Choi et al. 2020a
2	Trunk Exercise with Unstable Surface may produce greater improvements in gait endurance than Trunk Exercise with Stable Surface or conventional therapy.	1	Tirupatamma et al. 2019

2	Sensory training with Trunk-centred Bobath exercise may not have a difference in efficacy when compared to Trunk-centred Bobath exercise for improving gait endurance.	1	Karaca et al. 2024

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Trunk Training may produce greater improvements in functional mobility than Conventional Therapy.	9	Nadeem et al. 2024; Mahmood et al. 2022; Kim et al. 2022b; Haruyama et al. 2017; Büyükavci et al. 2016; Cabanas-Valdes et al. 2016; Jung et al. 2014; Chung et al. 2013; Saeys et al. 2012
2	Trunk stabilization exercise using weights with general physiotherapy may produce greater improvements in functional mobility than Trunk stabilization without weights with general physiotherapy.	1	Kim et al. 2022b

COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Trunk Training with Tilted Platforms when compared to Trunk Training with Horizontal Platforms for improving cognition.	1	Fujino et al. 2016
1b	Trunk Exercise with Unstable Surface may produce greater improvements in cognition than Trunk Exercise with Stable Surface or conventional therapy.	1	Khurana et al. 2022
1b	There is conflicting evidence about the effect of Trunk Training with Visual or Auditory Feedback when compared to Conventional Therapy for improving cognition.	1	De Seze et al. 2001

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Trunk Training may not have a difference in efficacy when compared to Conventional Therapy for improving upper extremity function.	2	Büyükavci et al. 2016; Saeys et al. 2012

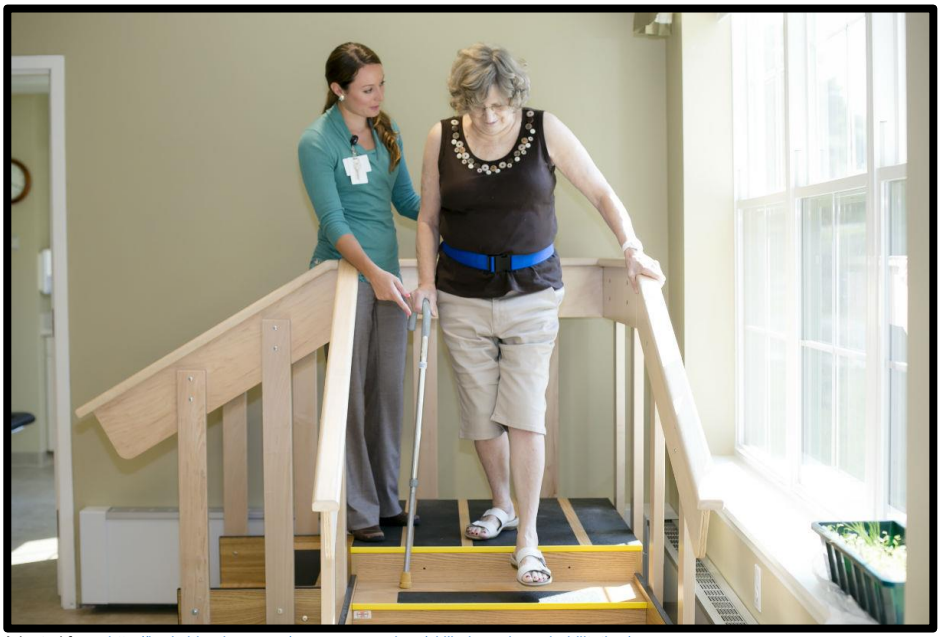
1b	Trunk Exercise with Unstable Surface may not have a difference in efficacy when compared to Trunk Exercise with Stable Surface or conventional therapy for improving upper extremity function.	1	Lee et al. 2020c

Key Points

- Trunk Training may be beneficial for improving motor recovery, biomechanical balance measures, gait speed, functional mobility, and balance, but not biomechanical gait measures, muscle strength, range of motion, activities of daily living, gait endurance, and quality of life, after stroke when compared to Conventional Therapy.
- Trunk stabilization exercise using weights with general physiotherapy may be beneficial for improving biomechanical balance measures, gait speed, functional mobility, and balance after stroke when compared to Trunk stabilization without weights with general physiotherapy.
- Trunk Training with Physio Equipment may be beneficial for improving biomechanical balance measures and gait endurance, but not biomechanical gait measures and gait speed, after stroke when compared to Trunk stabilization exercises with conventional physical exercise; the literature is mixed regarding functional mobility and balance.
- Trunk stabilization exercise with Pelvic compression belt on paretic side and comprehensive rehabilitation therapy may be beneficial for improving biomechanical gait measures, gait speed, and gait endurance, but not balance, after stroke when compared to Trunk stabilization exercise with Pelvic compression belt on non- paretic side and comprehensive rehabilitation therapy.
- Segmental mid-thoracic mobilization with neurodevelopmental therapy may be beneficial for improving quality of life, but not biomechanical balance measures and aerobic measures, after stroke when compared to Foam roller exercises with neurodevelopmental therapy.
- Trunk Training with Tilted Platforms may be beneficial for improving sensory and proprioceptive function, activities of daily living, and balance, but not motor recovery, after stroke when compared to Trunk Training with Horizontal Platforms.
- Trunk Exercise with Unstable Surface may be beneficial for improving biomechanical balance measures, muscle strength, gait speed, gait endurance, balance, and falls and fear of falling, but not motor recovery, sensory and proprioceptive function, and functional mobility, after stroke when compared to Trunk Exercise with Stable Surface or conventional therapy.
- Core stability training on stable surface may not be beneficial for improving biomechanical balance measures, muscle strength, balance, and falls and fear of falling after stroke when compared to Core stability training on unstable surface.
- Stable trunk training with plinth may not be beneficial for improving activities of daily living, gait speed, functional mobility, balance, and quality of life after stroke when compared to Unstable trunk training with Swiss ball.
- Trunk Training Combined with Robotics may be beneficial for improving motor recovery, biomechanical balance measures, muscle strength, and balance after stroke when compared to Conventional Therapy; the literature is mixed regarding biomechanical gait measures and functional mobility.
- Trunk Training Combined with Dual-Task Training may be beneficial for improving gait speed, functional mobility, balance, and quality of life after stroke when compared to Trunk Training.
- Trunk Training may be beneficial for improving gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Cognitive Training.
- Dynamic Neuromuscular Stabilization may be beneficial for improving range of motion and functional mobility, but not biomechanical gait measures, balance, and falls and fear of falling, after stroke when compared to Conventional Core Exercises; the literature is mixed regarding muscle strength.
- Trunk Training with Visual or Auditory Feedback may be beneficial for improving biomechanical gait measures, gait speed, functional mobility, balance, and falls and fear of falling, but not spasticity and activities of daily living, after stroke when compared to Conventional Therapy; the literature is mixed regarding muscle strength.
- Trunk Training with Balance Training and transcutaneous electrical nerve stimulation may be beneficial for improving sensory and proprioceptive function, but not balance, after stroke when compared to Treadmill Training and Placebo transcutaneous electrical nerve stimulation.

- Different Trunk Muscle Activation Exercises Compared to Each other may be beneficial for improving balance after stroke when compared to Bobath based trunk training with Conventional therapy; the literature is mixed regarding neurophysiological measures.
- Trunk stabilization exercise with abdominal hallowing with Conventional rehabilitation program may not be beneficial for improving gait speed, balance, and functional mobility after stroke when compared to Trunk stabilization exercise with bracing maneuver with Conventional rehabilitation program.
- Trunk Training with Delayed may not be beneficial for improving motor recovery, neurophysiological measures, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Real-Time Visual Feedback.
- Kneeling Training may be beneficial for improving balance, but not motor recovery, biomechanical gait measures, and range of motion, after stroke when compared to Treadmill Training.
- Bobath with Core stability training may be beneficial for improving balance after stroke when compared to Conventional physical therapy.
- Metronome training with core strengthening and general balance exercises may be beneficial for improving functional mobility after stroke when compared to Core strengthening with general balance exercises.
- Core muscle training with Functional electrical stimulation may be beneficial for improving muscle strength, gait speed, and balance after stroke when compared to Core muscle training; the literature is mixed regarding functional mobility.
- Sensory training with Trunk-centred Bobath exercise may be beneficial for improving sensory and proprioceptive function, but not activities of daily living, gait endurance, and balance, after stroke when compared to Trunk-centred Bobath exercise.
- Space Balance 3D system for active trunk training with conventional physical and occupational therapy may be beneficial for improving muscle strength and balance after stroke when compared to General trunk training with Conventional physical and occupational physiotherapy.
- Trunk rehabilitation with Kinesio taping may not be beneficial for improving biomechanical balance measures after stroke when compared to Trunk rehabilitation with Placebo taping.
- Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit) may be beneficial for improving balance, but not biomechanical gait measures, after stroke when compared to Trunk stabilization exercises; the literature is mixed regarding muscle strength.
- Smartphone visual feedback for trunk control training with Conventional care may be beneficial for improving functional mobility and balance after stroke when compared to Conventional care.
- Trunk neuromuscular electrical stimulation with Core muscle training may not be beneficial for improving activities of daily living after stroke when compared to Core Training; the literature is mixed regarding balance.
- Trunk neuromuscular electrical stimulation with Core muscle training may not be beneficial for improving activities of daily living and balance after stroke when compared to Trunk neuromuscular electrical stimulation.
- Core stability exercises with real time feedback and conventional physical therapy may be beneficial for improving gait speed and functional mobility, but not biomechanical gait measures, after stroke when compared to Core stability exercises with conventional physical therapy.
- Core stability training on stable surface may be beneficial for improving biomechanical balance measures, muscle strength, balance, and falls and fear of falling after stroke when compared to Individualized physiotherapy.
- Stable trunk training with plinth may be beneficial for improving activities of daily living, gait speed, balance, and quality of life after stroke when compared to Standard physiotherapy.
- Unstable trunk training with Swiss ball may be beneficial for improving activities of daily living, gait speed, balance, and quality of life after stroke when compared to Standard physiotherapy.
- Trunk stabilization exercise with Pelvic compression belt on paretic side with comprehensive rehabilitation therapy may not be beneficial for improving balance after stroke when compared to Trunk stabilization exercise with Pelvic compression belt on non- paretic side with comprehensive rehabilitation therapy.
- Aquatic therapy (Halliwick, Watsu, and Trunk Training) may not be beneficial for improving gait speed after stroke when compared to Trunk control exercises; Aquatic therapy (Halliwick, Watsu, and Trunk

Training) may result in lesser improvements in biomechanical gait measures when compared to Trunk control exercises.



Summary of Key Points: Trunk Training

Intervention	Control(s)	Function domain(s)	Effect
Trunk Training	Conventional Therapy	Motor recovery, biomechanical balance measures, gait speed, functional mobility, balance	+
Trunk Training	Conventional Therapy	Biomechanical gait measures, muscle strength, range of motion, activities of daily living, gait endurance, quality of life	–
Trunk stabilization exercise using weights with general physiotherapy	Trunk stabilization without weights with general physiotherapy	Biomechanical balance measures, gait speed, functional mobility, balance	+
Trunk Training with Physio Equipment	Trunk stabilization exercises with conventional physical exercise	Biomechanical balance measures, gait endurance	+
Trunk stabilization exercise with Pelvic compression belt on paretic side and comprehensive rehabilitation therapy	Trunk stabilization exercise with Pelvic compression belt on non-paretic side and comprehensive rehabilitation therapy	Biomechanical gait measures, gait speed, gait endurance	+
Trunk Training with Physio Equipment	Trunk stabilization exercises with conventional physical exercise	Gait endurance	+
Trunk Training with Physio Equipment	Trunk stabilization exercises with conventional physical exercise	Biomechanical gait measures, gait speed	–
Segmental mid-thoracic mobilization with neurodevelopmental therapy	Foam roller exercises with neurodevelopmental therapy	Quality of life	+
Segmental mid-thoracic mobilization with neurodevelopmental therapy	Foam roller exercises with neurodevelopmental therapy	Biomechanical balance measures, aerobic measures	–
Trunk Training with Tilted Platforms	Trunk Training with Horizontal Platforms	Sensory and proprioceptive function, activities of daily living, balance	+
Trunk Training with Tilted Platforms	Trunk Training with Horizontal Platforms	Motor recovery	–
Trunk Exercise with Unstable Surface	Trunk Exercise with Stable Surface or conventional therapy	Biomechanical balance measures, muscle strength, gait speed, gait endurance, balance, falls and fear of falling	+
Trunk Exercise with Unstable Surface	Trunk Exercise with Stable Surface or conventional therapy	Motor recovery, sensory and proprioceptive function, functional mobility	–
Core stability training on stable surface	Core stability training on unstable surface	Biomechanical balance measures, muscle strength, balance, falls and fear of falling	–
Stable trunk training with plinth	Unstable trunk training with Swiss ball	Activities of daily living, gait speed, functional mobility, balance, quality of life	–
Trunk Training Combined with Robotics	Conventional Therapy	Motor recovery, biomechanical balance measures, muscle strength, balance	+
Trunk Training Combined with Robotics	Conventional Therapy	Biomechanical gait measures, functional mobility	=

Trunk Training Combined with Dual-Task Training	Trunk Training	Gait speed, functional mobility, balance, quality of life	+
Trunk Training	Cognitive Training	Gait speed, functional mobility, balance	+
Trunk Training	Cognitive Training	Biomechanical gait measures	–
Dynamic Neuromuscular Stabilization	Conventional Core Exercises	Range of motion, functional mobility	+
Dynamic Neuromuscular Stabilization	Conventional Core Exercises	Biomechanical gait measures, balance, falls and fear of falling	–
Dynamic Neuromuscular Stabilization	Conventional Core Exercises	Muscle strength	=
Trunk Training with Visual or Auditory Feedback	Conventional Therapy	Biomechanical gait measures, gait speed, functional mobility, balance, falls and fear of falling	+
Trunk Training with Visual or Auditory Feedback	Conventional Therapy	Spasticity, activities of daily living	–
Trunk Training with Visual or Auditory Feedback	Conventional Therapy	Muscle strength	=
Trunk Training with Balance Training and transcutaneous electrical nerve stimulation	Treadmill Training and Placebo transcutaneous electrical nerve stimulation	Sensory and proprioceptive function	+
Trunk Training with Balance Training and transcutaneous electrical nerve stimulation	Treadmill Training and Placebo transcutaneous electrical nerve stimulation	Balance	–
Different Trunk Muscle Activation Exercises Compared to Each other	Bobath based trunk training with Conventional therapy	Balance	+
Trunk stabilization exercise with abdominal hallowing with Conventional rehabilitation program	Trunk stabilization exercise with bracing maneuver with Conventional rehabilitation program	Gait speed, balance, functional mobility	–
Different Trunk Muscle Activation Exercises Compared to Each other	Bobath based trunk training with Conventional therapy	Neurophysiological measures	=
Trunk Training with Delayed	Real-Time Visual Feedback	Motor recovery, neurophysiological measures, activities of daily living, gait speed, functional mobility, balance	–
Kneeling Training	Treadmill Training	Balance	+
Kneeling Training	Treadmill Training	Motor recovery, biomechanical gait measures, range of motion	–
Bobath with Core stability training	Conventional physical therapy	Balance	+
Metronome training with core strengthening and general balance exercises	Core strengthening with general balance exercises	Functional mobility	+
Core muscle training with Functional electrical stimulation	Core muscle training	Muscle strength, gait speed, balance	+
Core muscle training with Functional electrical stimulation	Core muscle training	Functional mobility	=
Sensory training with Trunk-centred Bobath exercise	Trunk-centred Bobath exercise	Sensory and proprioceptive function	+

Sensory training with Trunk-centred Bobath exercise	Trunk-centred Bobath exercise	Activities of daily living, gait endurance, balance	–
Space Balance 3D system for active trunk training with conventional physical and occupational therapy	General trunk training with Conventional physical and occupational physiotherapy	Muscle strength, balance	+
Trunk rehabilitation with Kinesio taping	Trunk rehabilitation with Placebo taping	Biomechanical balance measures	–
Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit)	Trunk stabilization exercises	Balance	+
Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit)	Trunk stabilization exercises	Biomechanical gait measures	–
Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit)	Trunk stabilization exercises	Muscle strength	=
Smartphone visual feedback for trunk control training with Conventional care	Conventional care	Functional mobility, balance	+
Trunk neuromuscular electrical stimulation with Core muscle training	Core Training	Activities of daily living	–
Trunk neuromuscular electrical stimulation with Core muscle training	Core Training	Balance	=
Trunk neuromuscular electrical stimulation with Core muscle training	Trunk neuromuscular electrical stimulation	Activities of daily living, balance	–
Core stability exercises with real time feedback and conventional physical therapy	Core stability exercises with conventional physical therapy	Gait speed, functional mobility	+
Core stability exercises with real time feedback and conventional physical therapy	Core stability exercises with conventional physical therapy	Biomechanical gait measures	–
Trunk stabilization exercise with Pelvic compression belt on paretic side and comprehensive rehabilitation therapy	Trunk stabilization exercise with Pelvic compression belt on non-paretic side and comprehensive rehabilitation therapy	Balance	–
Core stability training on stable surface	Individualized physiotherapy	Biomechanical balance measures, muscle strength, balance, falls and fear of falling	+
Stable trunk training with plinth	Standard physiotherapy	Activities of daily living, gait speed, balance, quality of life	+
Unstable trunk training with Swiss ball	Standard physiotherapy	Activities of daily living, gait speed, balance, quality of life	+
Trunk Training with Physio Equipment	Trunk stabilization exercises with conventional physical exercise	Functional mobility, balance	=
Trunk stabilization exercise with Pelvic compression belt on paretic side with comprehensive rehabilitation therapy	Trunk stabilization exercise with Pelvic compression belt on non-paretic side with comprehensive rehabilitation therapy	Balance	–
Aquatic therapy (Halliwick, Watsu, and Trunk Training)	Trunk control exercises	Biomechanical gait measures, gait speed	–

Task-Specific Training

Adopted from: http://berkshireplace.com/programs-services/skilled-nursing-rehabilitation/

Task-specific training, also referred to as task-oriented, goal-directed, or functional task practice, involves therapy in which patients perform practical motor tasks that would be used in their everyday life, such as walking up the stairs. Tasks should be relevant, repetitive, and should be designed to progress towards performance of the whole task while being reinforced with feedback (Hubbard et al., 2009).

Task-specific circuit training is a tailored intervention program targeting balance, gait, strength, aerobic capacity, and range of movement. The training involves performing various exercises at different stations and is often performed in groups. In addition to lower limb recovery, benefits associated with circuit training include peer support and social interaction, as well as more efficient use of therapy staff.

A total of 48 RCTs were found that evaluated Task-Specific training for lower extremity motor rehabilitation. Six RCTs compared Task-Specific Training with Conventional Therapy (Song et al. 2024; Ain et al. 2022; Arabzadeh et al. 2018; Ntsiea et al. 2015; Richards et al. 2004; Salbach et al. 2004). Two RCTs evaluated Task oriented training with altered sensory input (Kuberan et al. 2017; Park & Won 2017). Two RCTs compared Task Oriented sitting Reach Training with Sham Training (Dean et al. 2007; Dean et al. 1997). One RCT compared Task Specific Treadmill Training with Standard Treadmill Training (Kwon et al. 2015). One RCT compared Task-Oriented Training with Speed Dependent Treadmill Training (Sharma et al. 2014). One RCT compared Task Oriented Resistance Training with No Treatment (Yang et al. 2006). Four RCTs compared Task Oriented Gait Training with Conventional Training (Knox et al. 2018; Qurat-ul-Ain et al. 2018; Qurat-ul-Ain et al. 2018; Richards et al. 1993). Four RCTs compared Task Specific Circuit Training with Conventional/Sham (Martins et al. 2020; Kim et al. 2016d; English et al. 2015; Indurkar et al. 2013). One RCT compared Task-Specific Training with Orthoses (Kwakkel & Wagenaar 2002). One RCT compared Task Oriented Leg Training with Body Weight Support Training (Brunelli et al. 2019). One RCT compared Activity Repetition Training with Task Oriented Training (Ghous et al. 2017). One RCT evaluated Task-Specific Training Different Modalities (Gjelsvik et al. 2014). Eight RCTs compared Task Specific Training Combined with Other Therapies with Task Specific Therapy (Jeong et al. 2023; Patra et al. 2023; Kim et al. 2021b; Malik et al. 2021; Cha et al. 2016; Marin et al. 2013; Verma et al. 2011; Kluding et al. 2008). One RCT compared Lower body with Upper Body Task Specific Training (Dean et al. 2000). Two RCTs compared High Intensity Task-Specific Training with Low Intensity Training or vs Conventional Therapy (Outermans et al.2004). Two RCTs compared Task Oriented Training with Tilt Table with Tilt Table Alone (Kim et al. 2015g; Kim et al. 2015g). One RCT compared Task-Specific Circuit Training with Group Activities (Mudge et al. 2009). One RCT compared Task-Specific Training with Proprioceptive Neuromuscular Facilitation (Anandan et al. 2020). Three RCTs compared Group Task-Oriented Circuit Training with Conventional Training (Ali et al. 2020; Renner et al. 2016; Vandeport et al. 2012). Three RCTs evaluated Task-related Training combined with TENS (Ng et al. 2016; Hui-Chan et al. 2009; Ng & Hui-Chan 2007). Two RCTs compared Task-Specific Training with Bobath Concept

Approach with Task-Specific Training (Brock et al. 2011; Mudie et al. 2002). One RCT compared Task-Specific Training with Trunk Training (Priya et al. 2024).

In addition, fifteen RCTs in which Task-Specific training formed part of a combined or comparative intervention are cross-referenced at the end of Table 5; their primary listings appear in other tables.

The methodological details and results of all 48 RCTs are presented in Table 5.

Table 5. RCTs Evaluating Task-Specific Training for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Task-Specific Training vs Conventional Therapy		
Song et al. (2024) RCT (4) Nstart=40 Nend=40 TPS=Subacute A vs 0	E: Task-specific training + Conventional rehab C: Conventional rehab Duration: 40 min/d (2 x 20min), 5d/wk, 2wks	E vs C: gait parameters step length (+exp) step speed/ velocity (+exp) support phase (+exp) ROM shoulder flexion (+exp) elbow flexion (+exp)
Ain et al. (2022) RCT (4) Nstart=14 Nend=12 TPS=Chronic A vs 0	E: Task-specific training C: Conventional rehabilitation Duration: E: 8 wks	E vs C: Timed-Up-and-Go Test (+exp) Trunk Control Measurement Scale (-) 6-Minute Walk Test (-) Berg Balance Scale (+exp)
Arabzadeh et al. (2018) RCT (5) Nstart=20 Nend=20 TPS=Subacute A vs 0	E: Task-oriented Exercises C: Conventional Physiotherapy Duration: 50min/session, for 4wks	E vs C: Berg Balance Scale (+exp) Center of Pressure (COP) path length (+exp) COP Confidence Ellipse Area (+exp) Plantar Pressure Distribution (weight bearing) Affected side (-) Nonaffected Side (-)
Ntsiea et al. (2015) RCT (7) Nstart=80 Nend=80 TPS=Subacute A vs 0	E: Workplace intervention program (functional exercises) + Usual rehabilitation therapy C: Usual rehabilitation therapy Duration: 3-6 months	E vs C: Rate of return to work (+exp) Barthel index (+exp) Modified Rivermead mobility index (+exp) Montreal Cognitive Assessment (-) Stroke specific quality of asklife scale (-)
Richards et al. (2004) RCT (6) Nstart=63 Nend=60 TPS=Subacute A vs 0 Also in Table 9 (Treadmill Training)	E: Specialized task oriented locomotor training (includes using Tilt table, limb-load monitor, isokinetic device and treadmill training) + Conventional physiotherapy C: Conventional physiotherapy Duration: 60min/d, 5d/wk for 8wks	E vs C: Gait speed (-) Fugl-Meyer Assessment Leg (-) Arm (-) Timed Up and Go test (-) Barthel Index (-) Berg Balance Scale (-)
Salbach et al. (2004)	E: Task-oriented training	E vs C:

RCT (8) Nstart=91 Nend=84 TPS=Chronic A vs B	C: Upper extremity activities (sham) Duration: 60min/d, 3d/wk, for 6wks	6-min Walk Test (+exp) 5-m Walk (+exp) Timed Up and Go (-) Berg Balance Scale (-)
Task oriented training with altered sensory input		
Kuberan et al. (2017) RCT (5) Nstart=26 Nend=26 TPS=Chronic A + B vs 0	E: Task-oriented training + Altered sensory input C: Conventional physical therapy Duration: 45-60min/d, 5d/wk for 3wks	E vs C: Dynamic Gait Index (-) Timed Up-and-Go Test (+exp) Fall Efficacy Scale (+exp)
Park & Won (2017a) RCT (5) Nstart=28 Nend=26 TPS=Chronic A + B vs 0	E: Task-Oriented Training + altered sensory input C: Conventional Physical Training Duration: Physical Therapy 5d/wk, 4wks + Task-oriented Training 1hr/d, 3d/wk, 4wks	E vs C: Berg Balance Scale (+exp) Activities-Specific Balance Confidence Scale (-) Limit of Stability (-)
Task Oriented sitting Reach Training vs Sham Training		
Dean et al. (2007) RCT (7) Nstart=12 Nend=9 TPS=Acute A vs 0	E: Sitting Reach Training + Regular physiotherapy C: Sham Training + Regular physiotherapy Duration: 30min/d, 5d/wk, 2wks	E vs C: Maximum Sitting Reach Distance (modified functional reach test in sitting) (+exp) Reaching Time (+exp) Peak vertical force through affected foot during reaching (+exp) Peak vertical force through affected foot during standing up (+exp) 10-Meter Walking Test (-)
Dean et al. (1997) RCT (7) Nstart=20 Nend=19 TPS=Chronic A vs 0	E: Task- oriented reach training C: Sham training Duration: 30min/session, 10 sessions over 2wks	E vs C: Maximum distance reached Ipsilateral (+exp) Forward (+exp) Across (+exp) Peak Vertical Ground reaction forces Ipsilateral (-) Forward (+exp) Across (+exp) Hand movement time Ipsilateral (+exp) Forward (-) Across (+exp) 10-Meter Walk Test (-) Cognitive task Letter cancellation (+con) Word puzzle (-) Mathematics (-)
Task Specific Treadmill Training vs Standard Treadmill Training		
Kwon et al. (2015) RCT (5) Nstart=40 Nend=40 TPS=Chronic	E: Task-oriented treadmill training + conventional therapy C: Treadmill training + conventional therapy	E vs C: Timed Up & Go Test (+exp) 6-Minute Walk Test (+exp) Gait Stride length (+exp)

A1 vs A2 Also in Table 9 (Treadmill Training)	Duration: 30min/d, 5d/wk, 8wks conventional therapy, task-oriented treadmill training or conventional treadmill	Gait cycle (+exp) Cadence (+exp) Affected step length (+exp) Average speed (+exp) Affected single support (+exp) Affected step Affected speed (+exp)
Task-Oriented Training vs Speed Dependent Treadmill Training		
Sharma et al. (2014) RCT (5) Nstart=30 Nend=30 TPS=Chronic A vs B	E: Task-oriented training (focused on LE function and gait) C: Speed-dependent treadmill training Duration: 30min/d, 3d/wk, 4wks	E vs C: Berg Balance Scale (-) Rivermead Mobility Index (-)
Task Oriented Resistance Training vs No Treatment		
Yang et al. (2006) RCT (7) Nstart=48 Nend=48 TPS=Chronic A vs 0 Also in Table 21 (Strength and Resistance Training)	E: Task-oriented progressive resistance strength training C: No treatment Duration: 30min/d, 3d/wk for 4wks Task-oriented resistance training	E vs C: Muscle strength Hip flexor (+exp) Hip extensor (+exp) Knee flexor (+exp) Knee extensor (+exp) Ankle dorsiflexor (+exp) Ankle plantarflexor (+exp) 10-m Walk Velocity (+exp) Cadence (+exp) Stride length (+exp) 6-Minute Walk Test (+exp) Step Test (+exp) Timed Up-and-Go Test (+exp)
Task Oriented Gait Training vs Conventional Training		
Knox et al. (2018) RCT (7) Nstart=144 Nend=128 TPS=Subacute A vs B vs C Also in Table 21 (Strength and Resistance Training)	E1: Task oriented circuit gait training E2: Strength training of lower extremities C: Educational session on stroke management Duration: E1/E2: 60min/d, 6d/12wk intervention sessions & C: 90min/d, 1d	E1/E2 vs C: Berg Balance Scale (+exp1) 10m walk Comfortable Gait Speed (+exp1) Fast gait speed (+exp1) Timed Up and Go test (+exp1) 6-minute walk test (+exp1, +exp2) E1 vs E2: Berg Balance Scale (+exp1) 10-Meter Walk Test Comfortable Gait Speed (+exp1) Fast gait speed (+exp1) Timed Up and Go test (+exp1) 6-minute walk test (+exp1)
Qurat-ul-Ain et al. (2018) RCT (5) Nstart=36 Nend=30 TPS=Subacute A vs 0	E: Task specific Circuit Gait Training C: Conventional standard rehabilitation (Gait training) Duration: 40-50min/d, 4d/wk, for 6wks	E vs C: Timed Up-and-Go Test (+exp) Cadence (+exp) Step length (+exp) Step width (+exp)

Richards et al. (1993) RCT (6) Nstart=27 Nend=27 TPS=Acute A vs B vs 0 vs C Also in Table 9 (Treadmill Training)	E: Early, intensive, gait- oriented Task specific training (isokinetic device, treadmill, tilt table) + conventional hospital care C1: Early, intensive traditional PT approach + conventional hospital care C2: Conventional PT + conventional hospital care Duration: E/C1: 60min, 2sessions/d, 5d/wk, 5wks & C2: 60min/d, 5d/wk, 5wks	E vs C1 vs C2: 6m gait velocity (-) Fugle-Meyer Balance (-) Leg(-) Arm(No stats) Barthel index(-) Berg balance scale (No stats)
Task Specific Circuit Training vs Conventional/Sham		
Martins et al. (2020) RCT (8) Nstart=36 Nend=28 TPS=Chronic A vs B	E: Task-specific circuit training (focused on UE and LE mobility) C: Training program including stretching, memory exercises and health education Duration: 60min/d, 3d/wk, for 12wks	E vs C: Energy Expenditure (-) Human Activity Profile Adjusted Activity Score (-) Upper Extremity Performance Test for the Elderly (-) Walking Speed (-) Grip Strength (-) Knee Extensor Strength (-) Six-Minute Walk Test (-) Stroke Specific Quality of Life (+exp)
Kim et al. (2016d) RCT (6) Nstart=20 Nend=20 TPS=Acute A vs 0	E: Task-specific circuit training (focused on mobility and gait training) C: Conventional rehabilitation Duration: E: 90mins/d, 5d/wk, 4wks, C: 60mins/d, 5d/wk, 4wks	E vs C: Fugl-Meyer Assessment (-) Berg Balance Scale (-) 6-Minute Walk Test (-) Modified Barthel Index (-)
English et al. (2015) RCT (7) Nstart=283 Nend=261 TPS=Acute A vs 0 vs B1 vs C vs B2	E: Group Circuit class therapy C1: Usual care C2: Seven-day week usual therapy Duration: E: 3h/d, 5d/wk circuit class training; C: 5d/wk usual care C2: 7d/wk seven-day week therapy	E vs C1: 6min Walk test (-) Gait speed (-) Functional Ambulatory category (-) Functional Independence Measure (-) Wolf Motor Function test (-) Stroke Impact scale (-) Length of stay (-) Australian Quality of Life scale (-) E vs C2: 6min Walk test (-) Gait speed (-) Functional Ambulatory category (-) Functional Independence measure (-) Wolf Motor Function test (-) Stroke Impact scale (-) Length of stay (-) Australian Quality of Life scale (-) C1 vs C2 6min Walk test (-) Gait speed (-) Functional Ambulatory category (-) Functional Independence measure (-) Wolf Motor Function test (-) Stroke Impact scale (-)

		Length of stay (-) Australian Quality of Life scale (-)
Indurkar et al. (2013) RCT (4) Nstart=30 Nend=30 TPS=Chronic A vs 0 Also in Table 21 (Strength and Resistance Training)	E: Task Oriented circuit LE strength training + physiotherapy C: Conventional physiotherapy Duration: 30min/d, 6dwk for 3wks circuit training & 60min physiotherapy	E vs C: 6-min Walk Test (+exp) 5m Walk Test (+exp) Berg Balance (+exp) Timed Up and Go (+exp)
Task-Specific Training vs Orthoses		
Kwakkel & Wagenaar (2002) RCT (5) Nstart=53 Nend=53 TPS=Acute A1 vs A2 vs B	E1: Lower extremity task- specific rehabilitation E2: Upper extremity task- specific rehabilitation C: Immobilization of paretic LE and UE using inflatable pressure splint Duration: 30min/d, 5d/wk, for 20wks	E1 vs E2: 10m Walking speed (+exp1) Continuous relative phase paretic arm (-) Continuous relative phase non-paretic arm (-) Continuous relative phase non-paretic leg (-) Continuous relative phase paretic leg (-) Standard deviation of Continuous Relative Phase leg (-) Standard deviation of Continuous Relative Phase arm (-) E1 vs C: Walking speed (+exp1) Continuous relative phase paretic arm (-) Continuous relative phase non-paretic arm (-) Continuous relative phase non-paretic leg (-) Continuous relative phase paretic leg (-) Standard deviation of Continuous Relative Phase leg (-) Standard deviation of Continuous Relative Phase arm (-) E2 vs C: Walking speed (-) Continuous relative phase paretic arm (-) Continuous relative phase non-paretic arm (-) Continuous relative phase non-paretic leg (-) Continuous relative phase paretic leg (-) Standard deviation of Continuous Relative Phase leg (-) Standard deviation of Continuous Relative Phase arm (-)
Task Oriented Leg Training vs Body Weight Support Training		
Brunelli et al. (2019) RCT (6) Nstart=37 Nend=34 TPS=Acute A vs B	E: Conventional Physiotherapy + Body Weight Support training C: Conventional Physiotherapy + Task-oriented leg training Duration: 40-min PT + 40 min BWS or task specific trainings/d, 5d/wk, 4wks	E vs C: Functional Ambulation Classification (+exp) Rivermead Mobility Index (-) Barthel Index (-) 6-minute walk test (-)
Activity Repetition Training vs Task Oriented Training		
Ghous et al. (2017) RCT (4)	E: Activity Repetition (salat prayer) Training	E vs C: Berg Balance Scale (+exp)

Nstart=32 Nend=27 TPS=Chronic A vs B	C: Task oriented training Duration: 60min/d, 4d/wk, for 6 wks	Motor assessment scale (+exp) Time Up and Go Test (+exp)
Task-Specific Training Different Modalities		
Gjelsvik et al. (2014) RCT (7) Nstart=167 Nend=105 TPS=Acute A vs B vs 0	E1: early supported discharge to Day unit focussed on task- oriented training E2: early supported discharge to patients home focussed on task-oriented training C: Traditional treatment Duration: 5wks	E1 v E2 v C: Postural Assessment Scale for Stroke (-) Functional Ambulation categories (-) Trunk Impairment Scale-modified Norwegian version (+exp2) Timed Up-and-Go (-) 5-meter timed walk (-) Self-reported Numerical Rating Scale Walking (+exp1) Balance (-) ADL (+exp1, +exp2) Physical activity (-) Pain (-) Tiredness (-) E1 v E2: Postural Assessment Scale for Stroke (-) Functional Ambulation categories (-) Trunk Impairment Scale-modified Norwegian version (+exp2) Timed Up-and-Go (-) 5-meter timed walk (-) Self-reported Numerical Rating Scale Walking (-) Balance (-) ADL (-) Physical activity (-) Pain (-) Tiredness (-)
Task Specific Training Combined with Other Therapies vs Task Specific Therapy		
Jeong et al. (2023) Feasibility/pilot RCT (6) Nstart=38 Nend=38 TPS=Chronic A + B vs A vs 0	E1: Task-oriented training + Abdominal drawing-in maneuver, E2: Task-oriented training C: Conventional physical therapy Duration: 30min/d, 4d/wk, for 5wks	E1/E2 vs C: TIS (+exp1/2) PASS (+exp1/2) FRT (+exp1/2) BBS (+exp1/2) Weight-bearing ratio (+exp1/2) MBI (+exp1) E1 vs E2: TIS (+exp1) PASS (+exp1) FRT (+exp1) BBS (+exp1) Weight-bearing ratio (+exp1) MBI (+exp1)
Patra et al. (2023) RCT (4) Nstart=30 Nend=30 TPS=Subacute	E: Motor Relearning Program + Obstacle walking C: Motor Relearning Program Duration: 30min/d, 5d/wk, 4wks	E vs C: Dynamic gait index (+exp) MAS (+exp)

A + B vs A Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)		
Kim et al. (2021b) RCT (5) Nstart=45 Nend=37 TPS=Chronic A + B vs A vs 0	E1: Task-specific training + cognitive sensorimotor exercise E2: Task-specific training + conventional physical therapy C: Conventional physical therapy Duration: 60min/d, 5d/wk for 8wks	E1 vs E2: Proprioception error (+exp1) Composite spasticity score (-) Gastrocnemius muscle tone (-) 10-Metre Walk Test (-) E1 vs C: Proprioception error (+exp1, +exp2) Composite spasticity score (+exp1, +exp2) Gastrocnemius muscle tone (+exp1, +exp2) 10-Metre Walk Test (+exp1, +exp2)
Malik et al. Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

2	Task Oriented Gait Training may produce greater improvements in biomechanical gait measures than Conventional Training.	1	Qurat-ul-Ain et al. 2018
1b	Task Specific Training Combined with Other Therapies may not have a difference in efficacy when compared to Task Specific Therapy for improving biomechanical gait measures.	2	Verma et al. 2011; Kluding et al. 2008
2	There is conflicting evidence about the effect of Tilt table one-leg standing training with Conventional rehabilitation when compared to Tilt table progressive task- oriented training with Conventional rehabilitation for improving biomechanical gait measures.	1	Kim et al. 2015g
2	There is conflicting evidence about the effect of Transcranial direct current stimulation with Task-related training when compared to Task-related training for improving biomechanical gait measures.	1	Park et al. 2015b
2	Gait training with postural control visual feedback on monitor with task specific exercises may produce greater improvements in biomechanical gait measures than Gait training with physiotherapy.	1	Khallaf et al. 2014

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	There is conflicting evidence about the effect of Task-Specific Training when compared to Conventional Therapy for improving biomechanical balance measures.	1	Arabzadeh et al. 2018
2	Task oriented training with altered sensory input may not have a difference in efficacy when compared to Conventional physical therapy for improving biomechanical balance measures.	1	Park & Won 2017a
1b	There is conflicting evidence about the effect of Task Specific Training Combined with Other Therapies when compared to Task Specific Therapy for improving biomechanical balance measures.	2	Cha et al. 2016; Kluding et al. 2008
1b	Task-oriented training with Abdominal drawing-in maneuver may produce greater improvements in biomechanical balance measures than Task-oriented training.	1	Jeong et al. 2023
2	Task-Specific Training with Bobath Concept Approach may not have a difference in efficacy when compared to Task-Specific Training for improving biomechanical balance measures.	1	Mudie et al. 2002

1b	Task-specific training with Mental practice E2 Task-specific training and Cognitive training may produce greater improvements in biomechanical balance measures than No training.	1	Malouin et al. 2009

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Task Oriented Resistance Training may produce greater improvements in muscle strength than No Treatment.	1	Yang et al. 2006
1b	Task Specific Circuit Training may not have a difference in efficacy when compared to Conventional/Sham for improving muscle strength.	1	Martins et al. 2020
1b	Task Specific Training Combined with Other Therapies may not have a difference in efficacy when compared to Task Specific Therapy for improving muscle strength.	1	Marin et al. 2013
2	Tilt table one-leg standing training with Conventional rehabilitation may result in lesser improvements in muscle strength when compared to Tilt table progressive task- oriented training with Conventional rehabilitation.	1	Kim et al. 2015g
1a	Group Task-Oriented Circuit Training may not have a difference in efficacy when compared to Conventional Training for improving muscle strength.	2	Renner et al. 2016; Vandeport et al. 2012
1a	There is conflicting evidence about the effect of TENS with Task-related training when compared to TENS for improving muscle strength.	2	Hui-Chan et al. 2009; Ng & Hui-Chan 2007
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task-related training for improving muscle strength.	1	Hui-Chan et al. 2009
1b	There is conflicting evidence about the effect of Transcutaneous electrical nerve stimulation when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training for improving muscle strength.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training for improving muscle strength.	1	Ng & Hui-Chan 2007
2	Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care may not have a difference in efficacy when compared to Usual Care for improving muscle strength.	1	Mulder et al. 2024
1b	Task-specific training with Mental practice (Motor Imagery) may produce greater improvements in muscle strength than Task-specific training.	1	Kumar et al. 2016
1b	Transcutaneous electrical nerve stimulation with Task-related training may produce greater improvements in muscle strength than No active treatment (health education).	1	Chan et al. 2015
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to Sham transcutaneous electrical nerve stimulation with Task- related training for improving muscle strength.	1	Chan et al. 2015

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Task Specific Training Combined with Other Therapies may produce greater improvements in spasticity than Task Specific Therapy.	1	Patra et al. 2023
2	Task-specific training with cognitive sensorimotor exercise may not have a difference in efficacy when compared to Task-specific training with conventional physical therapy for improving spasticity.	1	Kim et al. 2021b
2	Task-specific training may produce greater improvements in spasticity than Proprioceptive Neuromuscular Facilitation.	1	Anandan et al. 2020
1b	Group Task-Oriented Circuit Training may not have a difference in efficacy when compared to Conventional Training for improving spasticity.	1	Ali et al. 2020
1a	TENS with Task-related training may not have a difference in efficacy when compared to TENS for improving spasticity.	2	Hui-Chan et al. 2009; Ng & Hui-Chan 2007
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task-related training for improving spasticity.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training for improving spasticity.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training for improving spasticity.	1	Ng & Hui-Chan 2007
1b	Task-oriented approach training + Conventional PT may produce greater improvements in spasticity than Task-oriented training only.	1	Patel et al. 2021b
1b	Constraint-induced movement therapy with task specific training may produce greater improvements in spasticity than modified constraint-induced movement therapy with task specific training.	1	Abdullahi et al. 2021
1b	Faradic electrical stimulation with Task-oriented exercise may produce greater improvements in spasticity than Russian electrical stimulation with Task-oriented exercises.	1	Ganesh et al. 2018
1b	Faradic electrical stimulation with Task-oriented exercise may produce greater improvements in spasticity than Conventional care with task- oriented approach or 40 min conventional care 5d/wk, for 6wks.	1	Ganesh et al. 2018
1b	Single dose of botulinum toxin-A (500U) with Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting) may not have a difference in efficacy when compared to Single dose of botulinum toxin-A (500U) or Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting) for improving spasticity.	1	Lannin et al. 2018

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Task Specific Training Combined with Other Therapies may produce greater improvements in range of motion than Task Specific Therapy.	1	Kluding et al. 2008
1b	Task Oriented Training with Tilt Table may produce greater improvements in range of motion than Tilt Table Alone.	1	Kim et al. 2015i

1b	There is conflicting evidence about the effect of Manual therapy with task oriented training and home exercise program when compared to conventional rehab for improving range of motion.	1	Traxler et al. 2024
1b	Manual therapy with task oriented training and home exercise program may produce greater improvements in range of motion than task oriented training with home exercise program.	1	Traxler et al. 2024
1b	There is conflicting evidence about the effect of Faradic electrical stimulation with Task-oriented exercise when compared to Russian electrical stimulation with Task-oriented exercises for improving range of motion.	1	Ganesh et al. 2018
1b	There is conflicting evidence about the effect of Faradic electrical stimulation with Task-oriented exercise when compared to Conventional care with task- oriented approach or 40 min conventional care 5d/wk, for 6wks for improving range of motion.	1	Ganesh et al. 2018

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Task Specific Circuit Training may not have a difference in efficacy when compared to Conventional/Sham for improving aerobic measures.	1	Martins et al. 2020
1b	Constraint-induced movement therapy with task specific training may produce greater improvements in aerobic measures than modified constraint-induced movement therapy with task specific training.	1	Abdullahi et al. 2021

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Task-specific training with cognitive sensorimotor exercise may produce greater improvements in sensory and proprioceptive function than Task-specific training with conventional physical therapy.	1	Kim et al. 2021b

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Task-Specific Training when compared to Conventional Therapy for improving activities of daily living.	2	Ntsiea et al. 2015; Richards et al. 2004
1b	Task Oriented Gait Training may not have a difference in efficacy when compared to Conventional Training for improving activities of daily living.	1	Richards et al. 1993
1a	Task Specific Circuit Training may not have a difference in efficacy when compared to Conventional/Sham for improving activities of daily living.	2	Kim et al. 2016d; English et al. 2015
1b	Task Oriented Leg Training may not have a difference in efficacy when compared to Body Weight Support Training for improving activities of daily living.	1	Brunelli et al. 2019
1b	Early supported discharge to Day unit focussed on task- oriented training may not have a difference in efficacy when compared to Traditional treatment for improving activities of daily living.	1	Gjelsvik et al. 2014

1b	Task Specific Training Combined with Other Therapies may produce greater improvements in activities of daily living than Task Specific Therapy.	1	Jeong et al. 2023
1b	Task-oriented training with Abdominal drawing-in maneuver may produce greater improvements in activities of daily living than Task-oriented training.	1	Jeong et al. 2023
1b	Task-oriented training with Abdominal drawing-in maneuver may produce greater improvements in activities of daily living than Conventional physical therapy.	1	Jeong et al. 2023
1b	Task-oriented training may not have a difference in efficacy when compared to Conventional physical therapy for improving activities of daily living.	1	Jeong et al. 2023
1b	Task Oriented Training with Tilt Table may produce greater improvements in activities of daily living than Tilt Table Alone.	1	Kim et al. 2015i
1b	Group Task-Oriented Circuit Training may not have a difference in efficacy when compared to Conventional Training for improving activities of daily living.	1	Vandeport et al. 2012
2	Task-Specific Training with Bobath Concept Approach may not have a difference in efficacy when compared to Task-Specific Training for improving activities of daily living.	1	Mudie et al. 2002
1b	Task-oriented approach training + Conventional PT may produce greater improvements in activities of daily living than Task-oriented training only.	1	Patel et al. 2021b
2	Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care may not have a difference in efficacy when compared to Usual Care for improving activities of daily living.	1	Mulder et al. 2024
1b	Bihemispheric transcranial direct current stimulation with task oriented training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with task oriented therapy for improving activities of daily living.	1	Hsu et al. 2023
1b	Visual scanning exercises with task specific activities may not have a difference in efficacy when compared to Placebo eye exercises with task specific activities(not sham) for improving activities of daily living.	1	Batool et al. 2022
1b	Single dose of botulinum toxin-A (500U) with Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting) may not have a difference in efficacy when compared to Single dose of botulinum toxin-A (500U) or Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting) for improving activities of daily living.	1	Lannin et al. 2018

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Task-Specific Training may produce greater improvements in gait speed than Conventional Therapy.	2	Song et al. 2024; Richards et al. 2004
1a	Task Oriented sitting Reach Training may not have a difference in efficacy when compared to Sham Training for improving gait speed.	2	Dean et al. 2007; Dean et al. 1997
2	Task Specific Treadmill Training may produce greater improvements in gait speed than Treadmill Training.	1	Kwon et al. 2015
1b	Task Oriented Resistance Training may produce greater improvements in gait speed than No Treatment.	1	Yang et al. 2006
1a	Task Oriented Gait Training may produce greater improvements in gait speed than Conventional Training.	2	Knox et al. 2018; Richards et al. 1993

1b	Task oriented circuit gait training may produce greater improvements in gait speed than Strength training of lower extremities.	1	Knox et al. 2018
1a	Task Specific Circuit Training may not have a difference in efficacy when compared to Conventional/Sham for improving gait speed.	3	Martins et al. 2020; English et al. 2015; Indurkar et al. 2013
2	Lower extremity task- specific rehabilitation may produce greater improvements in gait speed than Upper extremity task- specific rehabilitation.	1	Kwakkel & Wagenaar 2002
2	Lower extremity task- specific rehabilitation may produce greater improvements in gait speed than Immobilization of paretic LE and UE using inflatable pressure splint.	1	Kwakkel & Wagenaar 2002
2	Upper extremity task- specific rehabilitation may not have a difference in efficacy when compared to Immobilization of paretic LE and UE using inflatable pressure splint for improving gait speed.	1	Kwakkel & Wagenaar 2002
1b	There is conflicting evidence about the effect of Task Specific Training Combined with Other Therapies when compared to Task Specific Therapy for improving gait speed.	1	Verma et al. 2011
2	Task-specific training with cognitive sensorimotor exercise may not have a difference in efficacy when compared to Task-specific training with conventional physical therapy for improving gait speed.	1	Kim et al. 2021b
2	There is conflicting evidence about the effect of Lower body when compared to Upper Body Task Specific Training for improving gait speed.	1	Dean et al. 2000
1b	High Intensity Task-Specific Training may produce greater improvements in gait speed than Low Intensity Training or Conventional Therapy.	1	Outermans et al. 2010
2	Tilt table one-leg standing training with Conventional rehabilitation may not have a difference in efficacy when compared to Tilt table progressive task- oriented training with Conventional rehabilitation for improving gait speed.	1	Kim et al. 2015g
1b	Task-Specific Circuit Training may not have a difference in efficacy when compared to Group Activities for improving gait speed.	1	Mudge et al. 2009
1a	Group Task-Oriented Circuit Training may not have a difference in efficacy when compared to Conventional Training for improving gait speed.	3	Ali et al. 2020; Renner et al. 2016; Vandeport et al. 2012
1b	Transcutaneous electrical nerve stimulation may produce greater improvements in gait speed than No treatment.	1	Hui-Chan et al. 2009
1a	TENS with Task-related training may produce greater improvements in gait speed than TENS.	2	Hui-Chan et al. 2009; Ng & Hui-Chan 2007
1b	Transcutaneous electrical nerve stimulation with Task-related training may produce greater improvements in gait speed than Placebo transcutaneous electrical nerve stimulation with Task-related training.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training for improving gait speed.	1	Hui-Chan et al. 2009
1b	TENS with Task-related training may produce greater improvements in gait speed than No treatment.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation may produce greater improvements in gait speed than No active treatment.	1	Ng & Hui-Chan 2007
1b	Transcutaneous electrical nerve stimulation with Task-related training may produce greater improvements in gait speed than transcutaneous electrical nerve stimulation or Placebo	1	Ng & Hui-Chan 2007

	transcutaneous electrical nerve stimulation with Task- related training.		
1b	Task-Specific Training with Bobath Concept Approach may produce greater improvements in gait speed than Task-Specific Training.	1	Brock et al. 2011
1b	Manual therapy with task oriented training and home exercise program may not have a difference in efficacy when compared to conventional rehab for improving gait speed.	1	Traxler et al. 2024
1b	Manual therapy with task oriented training and home exercise program may not have a difference in efficacy when compared to task oriented training with home exercise program for improving gait speed.	1	Traxler et al. 2024
2	Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care may not have a difference in efficacy when compared to Usual Care for improving gait speed.	1	Mulder et al. 2024

1b	Manual therapy with task oriented training and home exercise program may produce greater improvements in balance than conventional rehab.	1	Traxler et al. 2024
2	Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care may not have a difference in efficacy when compared to Usual Care for improving balance.	1	Mulder et al. 2024
1b	Dual transcranial direct current stimulation with Task-specific training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Task specific training for improving balance.	1	Toktas et al. 2024
1b	Visual scanning exercises with task specific activities may produce greater improvements in balance than Placebo eye exercises with task specific activities(not sham).	1	Batool et al. 2022
1b	Constraint-induced movement therapy with task specific training may not have a difference in efficacy when compared to modified constraint-induced movement therapy with task specific training for improving balance.	1	Abdullahi et al. 2021
1b	Transcutaneous electrical nerve stimulation with Task-related training may produce greater improvements in balance than No active treatment (health education).	1	Chan et al. 2015
1b	Transcutaneous electrical nerve stimulation with Task-related training may produce greater improvements in balance than Sham transcutaneous electrical nerve stimulation with Task- related training.	1	Chan et al. 2015

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	There is conflicting evidence about the effect of Task oriented training with altered sensory input when compared to Conventional physical therapy for improving falls and fear of falling.	2	Kuberan et al. 2017; Park & Won 2017a
1a	Group Task-Oriented Circuit Training may not have a difference in efficacy when compared to Conventional Training for improving falls and fear of falling.	2	Renner et al. 2016; Vandeport et al. 2012

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Task Specific Circuit Training may not have a difference in efficacy when compared to Conventional/Sham for improving quality of life.	2	Martins et al. 2020; English et al. 2015
1a	Group Task-Oriented Circuit Training may not have a difference in efficacy when compared to Conventional Training for improving quality of life.	2	Renner et al. 2016; Vandeport et al. 2012
1b	Task-related Training combined with transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to C: Sham transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy for improving quality of life.	1	Ng et al. 2016
1b	Manual therapy with task oriented training and home exercise program may produce greater improvements in quality of life than task oriented training with home exercise program.	1	Traxler et al. 2024
1b	There is conflicting evidence about the effect of Manual therapy with task oriented training and home exercise program when compared to conventional rehab for improving quality of life.	1	Traxler et al. 2024
2	Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care may not have a difference in efficacy when compared to Usual Care for improving quality of life.	1	Mulder et al. 2024
1b	Dual transcranial direct current stimulation with Task-specific training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Task specific training for improving quality of life.	1	Toktas et al. 2024

Other Associated Outcome Measures

MOOD			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Group Task-Oriented Circuit Training may not have a difference in efficacy when compared to Conventional Training for improving mood.	2	Renner et al. 2016; Vandeport et al. 2012
2	Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care may not have a difference in efficacy when compared to Usual Care for improving mood.	1	Mulder et al. 2024

FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Group Task-Oriented Circuit Training may not have a difference in efficacy when compared to Conventional Training for improving fatigue and sleep.	2	Renner et al. 2016; Vandeport et al. 2012
2	Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care may not have a difference in efficacy when compared to Usual Care for improving fatigue and sleep.	1	Mulder et al. 2024

COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Task-Specific Training may not have a difference in efficacy when compared to Conventional Therapy for improving cognition.	1	Ntsiea et al. 2015
1b	Group Task-Oriented Circuit Training may not have a difference in efficacy when compared to Conventional Training for improving cognition.	1	Vandeport et al. 2012

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Task-Specific Training may produce greater improvements in upper extremity function than Conventional Therapy.	2	Song et al. 2024; Richards et al. 2004
1a	Task Specific Circuit Training may not have a difference in efficacy when compared to Conventional/Sham for improving upper extremity function.	2	Martins et al. 2020; English et al. 2015
2	Task-specific training may produce greater improvements in upper extremity function than Proprioceptive Neuromuscular Facilitation.	1	Anandan et al. 2020
1b	Group Task-Oriented Circuit Training may not have a difference in efficacy when compared to Conventional Training for improving upper extremity function.	1	Vandeport et al. 2012
1b	There is conflicting evidence about the effect of Bihemispheric transcranial direct current stimulation with task oriented training when compared to Sham transcranial direct current stimulation with task oriented therapy for improving upper extremity function.	1	Hsu et al. 2023
1b	Single dose of botulinum toxin-A (500U) with Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting) may not have a difference in efficacy when compared to Single dose of botulinum toxin-A (500U) or Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting) for improving upper extremity function.	1	Lannin et al. 2018

Key Points

- Task-Specific Training may be beneficial for improving biomechanical gait measures, gait speed, and gait endurance, but not motor recovery and balance, after stroke when compared to Conventional Therapy; the literature is mixed regarding biomechanical balance measures, activities of daily living, and functional mobility.
- Task oriented training with altered sensory input may be beneficial for improving balance, but not biomechanical balance measures, after stroke when compared to Conventional physical therapy; the literature is mixed regarding falls and fear of falling and functional mobility.
- Task Oriented sitting Reach Training may be beneficial for improving biomechanical gait measures and balance, but not gait speed, after stroke when compared to Sham Training.

- Task Specific Treadmill Training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill Training.
- Task-Oriented Training may not be beneficial for improving functional mobility and balance after stroke when compared to Speed Dependent Treadmill Training.
- Task Oriented Resistance Training may be beneficial for improving biomechanical gait measures, muscle strength, gait speed, gait endurance, and functional mobility after stroke when compared to No Treatment.
- Task Oriented Gait Training may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility, but not activities of daily living and balance, after stroke when compared to Conventional Training.
- Task oriented circuit gait training may be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Strength training of lower extremities.
- Task Specific Circuit Training may not be beneficial for improving motor recovery, muscle strength, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Conventional/Sham.
- Lower extremity task- specific rehabilitation may be beneficial for improving gait speed, but not balance, after stroke when compared to Upper extremity task- specific rehabilitation.
- Task Oriented Leg Training may not be beneficial for improving activities of daily living and gait endurance after stroke when compared to Body Weight Support Training; the literature is mixed regarding functional mobility.
- Activity Repetition Training may be beneficial for improving functional mobility and balance after stroke when compared to Task Oriented Training.
- Early supported discharge to Day unit focussed on task- oriented training may not be beneficial for improving activities of daily living, functional mobility, and balance after stroke when compared to Traditional treatment.
- Task Specific Training Combined with Other Therapies may be beneficial for improving motor recovery, spasticity, range of motion, activities of daily living, gait endurance, functional mobility, and balance, but not biomechanical gait measures and muscle strength, after stroke when compared to Task Specific Therapy; the literature is mixed regarding biomechanical balance measures and gait speed.
- Task-oriented training with Abdominal drawing-in maneuver may be beneficial for improving biomechanical balance measures, activities of daily living, and balance after stroke when compared to Task-oriented training.
- Task-specific training with cognitive sensorimotor exercise may be beneficial for improving sensory and proprioceptive function, but not spasticity and gait speed, after stroke when compared to Task-specific training with conventional physical therapy.
- Lower body may be beneficial for improving gait endurance and functional mobility after stroke when compared to Upper Body Task Specific Training; the literature is mixed regarding gait speed.
- High Intensity Task-Specific Training may be beneficial for improving gait speed and gait endurance, but not balance, after stroke when compared to Low Intensity Training or Conventional Therapy.
- Task Oriented Training with Tilt Table may be beneficial for improving motor recovery, range of motion, and activities of daily living after stroke when compared to Tilt Table Alone.
- Tilt table one-leg standing training with Conventional rehabilitation may not be beneficial for improving gait speed after stroke when compared to Tilt table progressive task- oriented training with Conventional rehabilitation; the literature is mixed regarding biomechanical gait measures; Tilt table one-leg standing training with Conventional rehabilitation may result in lesser improvements in muscle strength when compared to Tilt table progressive task- oriented training with Conventional rehabilitation.
- Task-Specific Circuit Training may not be beneficial for improving gait speed and functional mobility after stroke when compared to Group Activities; the literature is mixed regarding gait endurance.
- Task-specific training may be beneficial for improving spasticity, functional mobility, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Group Task-Oriented Circuit Training may not be beneficial for improving muscle strength, spasticity, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Conventional Training.

- Task-related Training combined with transcutaneous electrical nerve stimulation may be beneficial for improving balance, but not gait endurance and quality of life, after stroke when compared to C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy; the literature is mixed regarding functional mobility.
- Transcutaneous electrical nerve stimulation may be beneficial for improving gait speed after stroke when compared to No treatment.
- TENS with Task-related training may be beneficial for improving gait speed, gait endurance, and functional mobility, but not spasticity, after stroke when compared to TENS; the literature is mixed regarding muscle strength.
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving gait speed and functional mobility, but not muscle strength, spasticity, and gait endurance, after stroke when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training.
- Transcutaneous electrical nerve stimulation may not be beneficial for improving spasticity, gait speed, gait endurance, and functional mobility after stroke when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training; the literature is mixed regarding muscle strength.
- Transcutaneous electrical nerve stimulation may be beneficial for improving gait speed after stroke when compared to No active treatment.
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving gait speed, but not muscle strength and spasticity, after stroke when compared to transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training.
- Task-Specific Training with Bobath Concept Approach may be beneficial for improving gait speed, but not biomechanical balance measures, activities of daily living, gait endurance, and balance, after stroke when compared to Task-Specific Training.
- Task-Specific Training may be beneficial for improving balance after stroke when compared to Trunk Training.
- Task-oriented approach training + Conventional PT may be beneficial for improving spasticity and activities of daily living after stroke when compared to Task-oriented training only.
- Manual therapy with task oriented training and home exercise program may be beneficial for improving functional mobility and balance, but not gait speed, after stroke when compared to conventional rehab; the literature is mixed regarding range of motion and quality of life.
- Manual therapy with task oriented training and home exercise program may be beneficial for improving range of motion, functional mobility, balance, and quality of life, but not gait speed, after stroke when compared to task oriented training with home exercise program.
- Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care may not be beneficial for improving muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Usual Care.
- Dual transcranial direct current stimulation with Task-specific training may not be beneficial for improving motor recovery, gait speed, functional mobility, balance, and quality of life after stroke when compared to Sham transcranial direct current stimulation with Task specific training.
- Bihemispheric transcranial direct current stimulation with task oriented training may be beneficial for improving motor recovery, but not activities of daily living, after stroke when compared to Sham transcranial direct current stimulation with task oriented therapy.
- Visual scanning exercises with task specific activities may be beneficial for improving balance, but not activities of daily living, after stroke when compared to Placebo eye exercises with task specific activities(not sham).
- Constraint-induced movement therapy with task specific training may be beneficial for improving spasticity and aerobic measures, but not motor recovery, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to modified constraint-induced movement therapy with task specific training.
- Faradic electrical stimulation with Task-oriented exercise may be beneficial for improving spasticity, but not functional mobility, after stroke when compared to Russian electrical stimulation with Task-oriented exercises; the literature is mixed regarding range of motion.

- Faradic electrical stimulation with Task-oriented exercise may be beneficial for improving spasticity, but not functional mobility, after stroke when compared to Conventional care with task- oriented approach or 40 min conventional care 5d/wk, for 6wks; the literature is mixed regarding range of motion.
- Single dose of botulinum toxin-A (500U) with Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting) may not be beneficial for improving spasticity, activities of daily living, and gait endurance after stroke when compared to Single dose of botulinum toxin-A (500U) or Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting).
- Task-specific training with Mental practice (Motor Imagery) may be beneficial for improving muscle strength and gait speed after stroke when compared to Task-specific training.
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving muscle strength and balance after stroke when compared to No active treatment (health education).
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving balance, but not muscle strength, after stroke when compared to Sham transcutaneous electrical nerve stimulation with Task- related training.
- Transcranial direct current stimulation with Task-related training may be beneficial for improving gait speed after stroke when compared to Task-related training; the literature is mixed regarding biomechanical gait measures.
- Gait training with postural control visual feedback on monitor with task specific exercises may be beneficial for improving biomechanical gait measures after stroke when compared to Gait training with physiotherapy.
- Task-specific training with Mental practice E2 Task-specific training and Cognitive training may be beneficial for improving biomechanical balance measures, but not motor recovery, gait speed, and functional mobility, after stroke when compared to No training.
- Task oriented circuit gait training may be beneficial for improving gait endurance after stroke when compared to Educational session on stroke management.
- Strength training of lower extremities may be beneficial for improving gait endurance after stroke when compared to Educational session on stroke management.
- Lower extremity task- specific rehabilitation may be beneficial for improving gait speed after stroke when compared to Immobilization of paretic LE and UE using inflatable pressure splint.
- Upper extremity task- specific rehabilitation may not be beneficial for improving gait speed after stroke when compared to Immobilization of paretic LE and UE using inflatable pressure splint.
- Task-oriented training with Abdominal drawing-in maneuver may be beneficial for improving activities of daily living and balance after stroke when compared to Conventional physical therapy.
- Task-oriented training may be beneficial for improving balance, but not activities of daily living, after stroke when compared to Conventional physical therapy.
- TENS with Task-related training may be beneficial for improving gait speed after stroke when compared to No treatment.

Summary of Key Points: Task-Specific Training

Intervention	Control(s)	Function domain(s)	Effect
Task-Specific Training	Conventional Therapy	Biomechanical gait measures, gait speed, gait endurance	+
Task-Specific Training	Conventional Therapy	Motor recovery, balance	–
Task-Specific Training	Conventional Therapy	Biomechanical balance measures, activities of daily living, functional mobility	=
Task oriented training with altered sensory input	Conventional physical therapy	Balance	+
Task oriented training with altered sensory input	Conventional physical therapy	Functional mobility, falls and fear of falling	=

Task oriented training with altered sensory input	Conventional physical therapy	Biomechanical balance measures	–
Task Oriented sitting Reach Training	Sham Training	Biomechanical gait measures, balance	+
Task Oriented sitting Reach Training	Sham Training	Gait speed	–
Task Specific Treadmill Training	Treadmill Training	Biomechanical gait measures, gait speed, gait endurance, functional mobility	+
Task-Oriented Training	Speed Dependent Treadmill Training	Functional mobility, balance	–
Task Oriented Resistance Training	No Treatment	Biomechanical gait measures, muscle strength, gait speed, gait endurance, functional mobility	+
Task Oriented Gait Training	Conventional Training	Biomechanical gait measures, gait speed, functional mobility	+
Task Oriented Gait Training	Conventional Training	Activities of daily living, balance	–
Task oriented circuit gait training	Strength training of lower extremities	Gait speed, gait endurance, functional mobility, balance	+
Task Specific Circuit Training	Conventional/Sham	Motor recovery, muscle strength, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, quality of life	–
Lower extremity task- specific rehabilitation	Upper extremity task- specific rehabilitation	Gait speed	+
Lower extremity task- specific rehabilitation	Upper extremity task- specific rehabilitation	Balance	–
Task Oriented Leg Training	Body Weight Support Training	Activities of daily living, gait endurance	–
Task Oriented Leg Training	Body Weight Support Training	Functional mobility	=
Activity Repetition Training	Task Oriented Training	Functional mobility, balance	+
Early supported discharge to Day unit focussed on task- oriented training	Traditional treatment	Activities of daily living, functional mobility, balance	–
Task Specific Training Combined with Other Therapies	Task Specific Therapy	Motor recovery, spasticity, range of motion, activities of daily living, gait endurance, functional mobility, balance	+
Task Specific Training Combined with Other Therapies	Task Specific Therapy	Biomechanical gait measures, muscle strength	–
Task Specific Training Combined with Other Therapies	Task Specific Therapy	Biomechanical balance measures, gait speed	=
Task-oriented training with Abdominal drawing-in maneuver	Task-oriented training	Biomechanical balance measures, activities of daily living, balance	+
Task-specific training with cognitive sensorimotor exercise	Task-specific training with conventional physical therapy	Sensory and proprioceptive function	+
Task-specific training with cognitive sensorimotor exercise	Task-specific training with conventional physical therapy	Spasticity, gait speed	–
Lower body	Upper Body Task Specific Training	Gait endurance, functional mobility	+

Lower body	Upper Body Task Specific Training	Gait speed	=
High Intensity Task-Specific Training	Low Intensity Training or vs Conventional Therapy	Gait speed, gait endurance	+
High Intensity Task-Specific Training	Low Intensity Training or vs Conventional Therapy	Balance	–
Task Oriented Training with Tilt Table	Tilt Table Alone	Motor recovery, range of motion, activities of daily living	+
Tilt table one-leg standing training with Conventional rehabilitation	Tilt table progressive task-oriented training with Conventional rehabilitation	Muscle strength, gait speed	–
Tilt table one-leg standing training with Conventional rehabilitation	Tilt table progressive task-oriented training with Conventional rehabilitation	Muscle strength	–
Task-Specific Circuit Training	Group Activities	Gait speed, functional mobility	–
Task-Specific Circuit Training	Group Activities	Gait endurance	=
Task-specific training	Proprioceptive Neuromuscular Facilitation	Spasticity, functional mobility, balance	+
Group Task-Oriented Circuit Training	Conventional Training	Muscle strength, spasticity, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Task-related Training combined with transcutaneous electrical nerve stimulation	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy	Balance	+
Task-related Training combined with transcutaneous electrical nerve stimulation	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy	Gait endurance, quality of life	–
Task-related Training combined with transcutaneous electrical nerve stimulation	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy	Functional mobility	=
Transcutaneous electrical nerve stimulation	No treatment	Gait speed	+
TENS with Task-related training	TENS	Gait speed, gait endurance, functional mobility	+
TENS with Task-related training	TENS	Spasticity	–
Transcutaneous electrical nerve stimulation with Task-related training	Placebo transcutaneous electrical nerve stimulation with Task-related training	Gait speed, functional mobility	+
Transcutaneous electrical nerve stimulation with Task-related training	Placebo transcutaneous electrical nerve stimulation with Task-related training	Muscle strength, spasticity, gait endurance	–
Transcutaneous electrical nerve stimulation	Placebo transcutaneous electrical nerve stimulation with Task-related training	Spasticity, gait speed, gait endurance, functional mobility	–

Transcutaneous electrical nerve stimulation	Placebo transcutaneous electrical nerve stimulation with Task-related training	Muscle strength	=
Transcutaneous electrical nerve stimulation	No active treatment	Gait speed	+
TENS with Task-related training	TENS	Gait speed	+
Transcutaneous electrical nerve stimulation with Task-related training	transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training	Gait speed	+
Transcutaneous electrical nerve stimulation with Task-related training	transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training	Muscle strength, spasticity	–
Task-Specific Training with Bobath Concept Approach	Task-Specific Training	Gait speed	+
Task-Specific Training with Bobath Concept Approach	Task-Specific Training	Biomechanical balance measures, activities of daily living, gait endurance, balance	–
Task-Specific Training	Trunk Training	Balance	+
Task-oriented approach training + Conventional PT	Task-oriented training only	Spasticity, activities of daily living	+
Manual therapy with task oriented training and home exercise program	conventional rehab	Functional mobility, balance	+
Manual therapy with task oriented training and home exercise program	conventional rehab	Gait speed	–
Manual therapy with task oriented training and home exercise program	task oriented training with home exercise program	Range of motion, functional mobility, balance, quality of life	+
Manual therapy with task oriented training and home exercise program	task oriented training with home exercise program	Gait speed	–
Manual therapy with task oriented training and home exercise program	conventional rehab	Range of motion, quality of life	=
Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care	Usual Care	Muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance, quality of life	–
Dual transcranial direct current stimulation with Task-specific training	Sham transcranial direct current stimulation with Task specific training	Motor recovery, gait speed, functional mobility, balance, quality of life	–
Bihemispheric transcranial direct current stimulation with task oriented training	Sham transcranial direct current stimulation with task oriented therapy	Motor recovery	+
Bihemispheric transcranial direct current stimulation with task oriented training	Sham transcranial direct current stimulation with task oriented therapy	Activities of daily living	–
Visual scanning exercises with task specific activities	Placebo eye exercises with task specific activities(not sham)	Balance	+
Visual scanning exercises with task specific activities	Placebo eye exercises with task specific activities(not sham)	Activities of daily living	–

Constraint-induced movement therapy with task specific training	modified constraint-induced movement therapy with task specific training	Spasticity, aerobic measures	+
Constraint-induced movement therapy with task specific training	modified constraint-induced movement therapy with task specific training	Motor recovery, gait speed, gait endurance, functional mobility, balance	–
Faradic electrical stimulation with Task-oriented exercise	Russian electrical stimulation with Task-oriented exercises	Spasticity	+
Faradic electrical stimulation with Task-oriented exercise	Russian electrical stimulation with Task-oriented exercises	Functional mobility	–
Faradic electrical stimulation with Task-oriented exercise	Russian electrical stimulation with Task-oriented exercises	Range of motion	=
Faradic electrical stimulation with Task-oriented exercise	Conventional care with task-oriented approach or 40 min conventional care 5d/wk, for 6wks	Functional mobility	–
Faradic electrical stimulation with Task-oriented exercise	Conventional care with task-oriented approach or 40 min conventional care 5d/wk, for 6wks	Range of motion	=
Faradic electrical stimulation with Task-oriented exercise	Conventional care with task-oriented approach or 40 min conventional care 5d/wk, for 6wks	Spasticity	+
Single dose of botulinum toxin-A (500U) with Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting)	Single dose of botulinum toxin-A (500U) or Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting)	Spasticity, activities of daily living, gait endurance	–
Task-specific training with Mental practice (Motor Imagery)	Task-specific training	Muscle strength, gait speed	+
Transcutaneous electrical nerve stimulation with Task-related training	No active treatment (health education)	Muscle strength, balance	+
Transcutaneous electrical nerve stimulation with Task-related training	Sham transcutaneous electrical nerve stimulation with Task-related training	Balance	+
Transcutaneous electrical nerve stimulation with Task-related training	Sham transcutaneous electrical nerve stimulation with Task-related training	Muscle strength	–
Transcranial direct current stimulation with Task-related training	Task-related training	Gait speed	+
Transcranial direct current stimulation with Task-related training	Task-related training	Biomechanical gait measures	=
Gait training with postural control visual feedback on monitor with task specific exercises	Gait training with physiotherapy	Biomechanical gait measures	+
Task-specific training with Mental practice E2 Task-specific training and Cognitive training	No training	Biomechanical balance measures	+
Task-specific training with Mental practice E2 Task-specific training and Cognitive training	No training	Motor recovery, gait speed, functional mobility	–
Task oriented circuit gait training	Educational session on stroke management	Gait endurance	+

Strength training of lower extremities	Educational session on stroke management	Gait endurance	+
Lower extremity task- specific rehabilitation	Immobilization of paretic LE and UE using inflatable pressure splint	Gait speed	+
Upper extremity task- specific rehabilitation	Immobilization of paretic LE and UE using inflatable pressure splint	Gait speed	−
Task-oriented training with Abdominal drawing-in maneuver	Conventional physical therapy	Activities of daily living, balance	+
Task-oriented training	Conventional physical therapy	Activities of daily living	−
Task-oriented training	Conventional physical therapy	Balance	+
TENS with Task-related training	No treatment	Gait speed	+

TENS with Task-related training	TENS	Muscle strength	=

Constraint-Induced Movement Therapy (CIMT)

Adopted from: https://unsplash.com/

CIMT of the lower extremity (CIMT-LE) draws many aspects of CIMT of the upper extremity. As in CIMT for the upper extremity, CIMT-LE is designed to overcome the tendency among hemiparetic patients to avoid the use of their paretic limb, a process termed “learned non-use”. Despite similarities of protocols used in CIMT such as motor activity logs, supervised training and shaping, there are key differences implemented in CIMT for the LE. Unique to the protocols used during CIMT-LE, is the omission of restraint of the stronger limb. This is rationalized by the risk of falls and related injuries. In addition, both lower limbs are required to produce a natural gait cycle and restraint of one limb may hinder shaping interventions aimed at promoting gait and functional ambulation (dos Anjos et al., 2020).

A total of nine RCTs were found that evaluated Constraint-Induced movement therapy (CIMT) for lower extremity motor rehabilitation. Five RCTs compared mCIMT Therapy or Conventional Rehabilitation with Neurodevelopmental Therapy or Conventional Rehabilitation (Menezes-Oliveira et al. 2024; Aloraini et al. 2022; Candan et al. 2019; Candan et al. 2017; Zhu et al. 2016b). One RCT compared mCIMT Use Therapy with Forced Use Therapy (Fuzaro et al. 2012). One RCT evaluated CIMT with Task-Specific Training (Abdullahi et al. 2021). One RCT compared VR Combined with CIMT with VR or Conventional Training (Choi et al. 2017a). One RCT compared CIMT With Immobilization with Without Immobilization (da Silva Filho et al. 2017).

In addition, two RCTs in which Constraint-Induced movement therapy (CIMT) formed part of a combined or comparative intervention are cross-referenced at the end of Table 6; their primary listings appear in other tables.

The methodological details and results of all nine RCTs are presented in Table 6.

Table 6. RCTs Evaluating Constraint-Induced Movement Therapy (CIMT) for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)
mCIMT vs Neurodevelopmental Therapy or Conventional Rehabilitation		
Menezes-Oliveira et al. (2024) RCT (6) Nstart=42 Nend=39 TPS=Chronic A vs 0	E: Lower extremity constraint induced movement therapy C: Conventional physiotherapy Duration: 2.5 hours, 15 days	E vs C: Mini-Bestest Assisstance (+exp) Performance (-) Confidence (-) 10 metre walk test (-) TUG (-) Gait deviation index (-) Step width (-) First double support (-) Single support (-) Second double support more affected side (-) less affected side (+exp) Step Length more affected (+exp) less affected (-) Cadence (-) Walking speed more affected (-) less affected (+exp)
Aloraini et al. (2022) RCT (7) Nstart=38 Nend=38 TPS=Chronic A vs 0	E: constraint-induced movement therapy for the lower extremity (CIMT-LE) C: Conventional rehab Duration: 3.5hrs/d, 5d/wk, 2wks	E vs C: FMA-LE(+exp) BBS(+exp) 10MWT(+exp) 6MWT(-)
Candan et al. (2019) RCT (6) Nstart=33 Nend=30 TPS=Chronic A + B vs C Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)	E: mCIMT + Neurodevelopmental therapy (NDT) C: NDT Duration: 60min/d, 3d/wk, 4wks NDT & 120min/d, 5d/wk, 2wks NDT or mCIMT	E vs C: Motricity Index (+exp) Stroke Specific Quality of Life Scale (-) Mobility (-) Energy, - Selfcare (-) Vision (-) Language (-) Productivity (-) UE function (-) Thinking (+exp) personality (+exp) Mood (+exp) Family (-), -Social roles (-) Stroke Impact Scale (+exp) Perceived recovery (+exp)
Candan et al. (2017) RCT (6)	E: mCIMT on paretic LE C: NDT	E vs C: Berg balance scale (+exp)

Nstart=33 Nend=30 TPS=Chronic A vs B	Duration: 120min/d, 5d/wk, 2wks	Functional Ambulation Category (+exp) Walking Velocity (-) Cadence (+exp) Step length ratio (+exp) Postural Symmetry Ratio (+exp)
Zhu et al. (2016b) RCT (5) Nstart=22 Nend=22 TPS=Subacute A vs 0	E: mCIMT + conventional rehabilitation C: Conventional Rehabilitation Duration: 120min/d, 5d/wk, 4wks mCIMT & 45min/d, 5d/wk, 4wks conventional therapy	E vs C: Centre of Mass (-) P1 (-) nP1 (-) P2 (-) nP2 (-) COM Y range (-) normalized COM Y (+exp) Velocity (-) normalized Velocity (+exp) Step Width (-) normalized Step Width (+exp) Step Length Affected Side (-) normalized Step Length Affected Side (-) Step Length non-affected side (-) normalized Step Length non-affected side (+exp) Paretic Swing time (-) Non-paretic swing time (+exp)
mCIMT vs Forced Use Therapy		
Fuzaro et al. (2012) RCT (6) Nstart=72 Nend=37 TPS=Chronic A vs B + C vs D vs B	E: mCIMT C: Forced use therapy Duration: E: 23h/d immobilization of Non Paretic upper limb + 50min/d, 5d/wk exercise training for Paretic upper limb, 5d/wk; 4wk C: 23h/d immobilization by restraint wearing of Non Paretic upper limb, 5d/wk, 4wk	E vs C: Stroke Impact scale (+exp) Berg Balance scale (-) Fugl-Meyer assessment (+exp) 10m Walk test (-) Timed Up and Go (-)
CIMT with Task-Specific Training		
Abdullahi et al. (2021) RCT (9) Nstart=58 Nend=56 TPS=Chronic A + B vs C + B Also in Table 5 (Task-Specific Training)	E: CIMT + task specific training C: mCIMT + task specific training Duration: 3h/d, 5d/wk, for 4wks	E vs C: Fugl Meyer (-) Berg Balance Scale (-) Rivermead Mobility Index (-) Modified Ashworth Scale (+exp) Ten-Meter Walk Test (-) Six-Minute Walk test (-) Rate of perceived exertion (+exp)
VR Combined with CIMT vs VR or Conventional Training		
Choi et al. Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

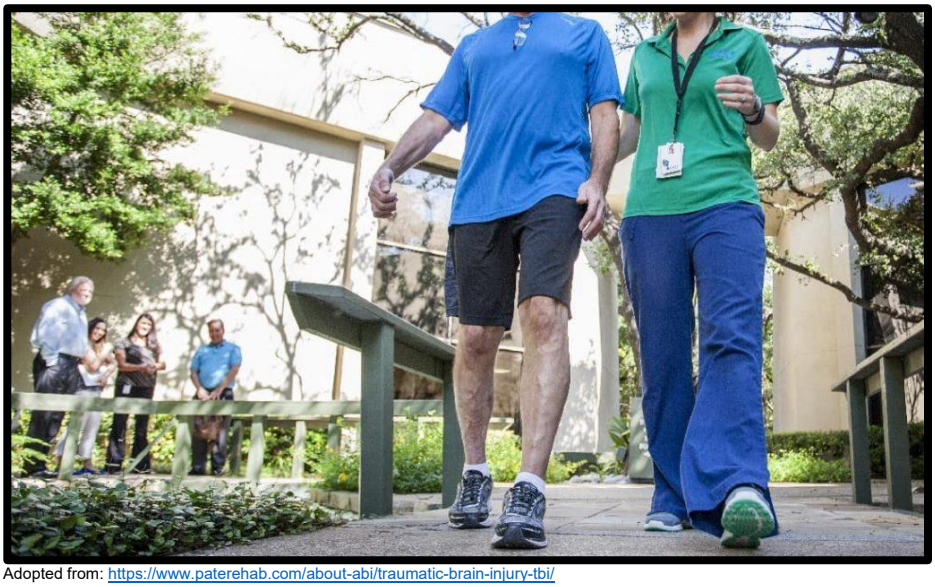
3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Modified constraint-induced movement therapy Therapy or Conventional Rehabilitation may not have a difference in efficacy	1	Candan et al. 2019

	when compared to Neurodevelopmental Therapy or Conventional Rehabilitation for improving quality of life.		
1b	Modified constraint-induced movement therapy Use Therapy may produce greater improvements in quality of life than Forced Use Therapy.	1	Fuzaro et al. 2012

Key Points



- Modified constraint-induced movement therapy Therapy or Conventional Rehabilitation may be beneficial for improving motor recovery, muscle strength, and balance, but not biomechanical gait measures, gait speed, gait endurance, and quality of life, after stroke when compared to Neurodevelopmental Therapy or Conventional Rehabilitation; the literature is mixed regarding functional mobility.
- Modified constraint-induced movement therapy Use Therapy may be beneficial for improving motor recovery and quality of life, but not gait speed, functional mobility, and balance, after stroke when compared to Forced Use Therapy.
- Constraint-induced movement therapy with task specific training may be beneficial for improving spasticity and aerobic measures, but not motor recovery, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to modified constraint-induced movement therapy with task specific training.
- Game-based constraint-induced movement therapy with Traditional physical therapy may be beneficial for improving biomechanical balance measures, but not gait speed, functional mobility, and balance, after stroke when compared to Traditional physical therapy.
- Game-based constraint-induced movement therapy with Traditional physical therapy may be beneficial for improving biomechanical gait measures and biomechanical balance measures, but not gait speed, functional mobility, and balance, after stroke when compared to General game-based training with Traditional physical therapy.
- Constraint-induced movement therapy With Immobilization may be beneficial for improving gait speed and functional mobility, but not balance, after stroke when compared to Without Immobilization.
- Healbot no pelvic mode may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to Conventional gait training with treadmill.
- Constraint induced movement training on treadmill with home exercises may not be beneficial for improving biomechanical gait measures, functional mobility, and balance after stroke when compared to Treadmill training.

Summary of Key Points: Constraint-Induced Movement Therapy (CIMT)

Intervention	Control(s)	Function domain(s)	Effect
Modified constraint-induced movement therapy Therapy or Conventional Rehabilitation	Neurodevelopmental Therapy or Conventional Rehabilitation	Motor recovery, muscle strength, balance	+
Modified constraint-induced movement therapy Therapy or Conventional Rehabilitation	Neurodevelopmental Therapy or Conventional Rehabilitation	Biomechanical gait measures, gait speed, gait endurance, quality of life	–
Modified constraint-induced movement therapy Therapy or Conventional Rehabilitation	Neurodevelopmental Therapy or Conventional Rehabilitation	Functional mobility	=
Modified constraint-induced movement therapy Use Therapy	Forced Use Therapy	Motor recovery, quality of life	+
Modified constraint-induced movement therapy Use Therapy	Forced Use Therapy	Gait speed, functional mobility, balance	–
Constraint-induced movement therapy with task specific training	modified constraint-induced movement therapy with task specific training	Spasticity, aerobic measures	+

Constraint-induced movement therapy with task specific training	modified constraint-induced movement therapy with task specific training	Motor recovery, gait speed, gait endurance, functional mobility, balance	–
Game-based constraint-induced movement therapy with Traditional physical therapy	Traditional physical therapy	Biomechanical balance measures	+
Game-based constraint-induced movement therapy with Traditional physical therapy	Traditional physical therapy	Gait speed, functional mobility, balance	–
Game-based constraint-induced movement therapy with Traditional physical therapy	General game-based training with Traditional physical therapy	Biomechanical gait measures, biomechanical balance measures	+
Game-based constraint-induced movement therapy with Traditional physical therapy	General game-based training with Traditional physical therapy	Gait speed, functional mobility, balance	–
Constraint-induced movement therapy With Immobilization	Without Immobilization	Gait speed, functional mobility	+
Constraint-induced movement therapy With Immobilization	Without Immobilization	Balance	–
Healbot no pelvic mode	Conventional gait training with treadmill	Gait speed, functional mobility, balance	+
Constraint induced movement training on treadmill with home exercises	Treadmill training	Biomechanical gait measures, functional mobility, balance	–

Non-Technological Overground Walking and Gait Training

Adopted from: https://www.paterehab.com/about-abi/traumatic-brain-injury-tbi/

Gait training is one of the most common interventions provided following a stroke (Jette et al., 2005). Overground gait training includes walking and related exercises with or without cueing from a physical therapist but does not include use of technology aids such as those used to administer body weight support (States et al., 2009).

A total of 40 RCTs were found that evaluated Non-Technological overground walking and gait training for lower extremity motor rehabilitation. Five RCTs compared Overground Walking with Treadmill Training (Gangopadhyay et al. 2021; Timmermans et al. 2021; Combs-Miller et al. 2014; Bonnyaud et al. 2013a; Bonnyaud et al. 2013a). Two RCTs compared High Intensity Overground Walking with Conventional Therapy (Shen et al. 2015; Gordon et al. 2013). Three RCTs compared Community-based gait training with conventional training (Kim et al. 2014d; Park et

al. 2011b; Lord et al. 2008). One RCT compared Bent Knee (Prowling) Gait Training with Conventional Therapy (Dalal et al. 2018). Eight RCTs compared Backward or Sideway Walking Training with Standing Practice or Conventional Therapy (Chatterjee et al. 2023; Kalyana et al. 2023; Huang et al. 2021; Sethy et al. 2021; Kale et al. 2019; Rose et al. 2018; Kim et al. 2017a; Yang et al. 2005). Five RCTs compared Stair or Ramp Training with Flat Surface Gait Training (Yoon-Hee et al. 2020; Park et al. 2015d; Seo & Kim 2015; Lee & Seo 2014d; Seo et al. 2014). One RCT compared Gait Training with Motor Imagery with Conventional Gait Training (Sawant 2020). Two RCTs compared Gait Training or Overground Walking with Feedback with Without Feedback (Kim et al. 2020b; Danks et al. 2016). Two RCTs compared Gait Training with Postural Assistance Support with Gait Training with Conventional Support (Kawakami et al. 2024; Dragin et al. 2014). Two RCTs compared Gait training with Insoles with Gait training with Conventional Shoes (Park et al. 2024a; Sheikh et al. 2016). Two RCTs compared Accurate Adaptability Walking with Steady State Walking (Muroi et al. 2024; Clark et al. 2021). One RCT compared Implicit Motor Learning with Walking with Explicit Motor Learning with Walking (Jie et al. 2021). One RCT compared Curved Gait Training with Straight Gait Training (Lee et al. 2024b). One RCT compared Gait Training on Sand with Gait Training on Firm Surface (Lee et al. 2023c). One RCT evaluated High-Intensity Walking Training with or without Step Activity Monitoring (Thompson et al. 2024).

In addition, 20 RCTs in which Non-Technological overground walking and gait training formed part of a combined or comparative intervention are cross-referenced at the end of Table 7; their primary listings appear in other tables.

The methodological details and results of all 40 RCTs are presented in Table 7.

Table 7. RCTs Evaluating Non-Technological Overground Walking and Gait Training for Lower Extremity Motor Rehabilitation

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

2	Stair or Ramp Training may produce greater improvements in biomechanical balance measures than Flat Surface Gait Training.	2	Lee & Seo 2014d; Seo et al. 2014
1b	Gait training with Insoles may produce greater improvements in biomechanical balance measures than Gait training with Conventional Shoes.	1	Sheikh et al. 2016
1b	Backward walking observational training & Conventional therapy may produce greater improvements in biomechanical balance measures than Landscape observational training (sham) & Conventional therapy.	1	Moon et al. 2022

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	High Intensity Overground Walking may not have a difference in efficacy when compared to Conventional Therapy for improving muscle strength.	1	Gordon et al. 2013
1b	Backward or Sideway Walking Training may not have a difference in efficacy when compared to Standing Practice or Conventional Therapy for improving muscle strength.	1	Huang et al. 2021
2	There is conflicting evidence about the effect of Stair or Ramp Training when compared to Flat Surface Gait Training for improving muscle strength.	1	Park et al. 2015d
1b	Conventional gait training therapy + Conductive (Petho) methods education may not have a difference in efficacy when compared to Conventional gait training for improving muscle strength.	1	Nagy et al. 2017
1b	Inclined treadmill training with overground walking may not have a difference in efficacy when compared to Regular treadmill training with overground walking for improving muscle strength.	1	Cheng et al. 2022

2	Gait training program (treadmill + overground walking) wearing a hip-assist robot may produce greater improvements in muscle strength than Gait training (treadmill training + over ground walking).	1	Lee et al. 2019a
2	Functional electrical stimulation of Dorsiflexors and Plantar Flexors with Overground Walking program may not have a difference in efficacy when compared to Overground Walking program for improving muscle strength.	1	Embrey et al. 2010

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Conventional gait training therapy + Conductive (Petho) methods education may not have a difference in efficacy when compared to Conventional gait training for improving spasticity.	1	Nagy et al. 2017
1b	Inclined treadmill training with overground walking may not have a difference in efficacy when compared to Regular treadmill training with overground walking for improving spasticity.	1	Cheng et al. 2022
1b	Overground walking training with i-Walker robotic assistive device may not have a difference in efficacy when compared to Conventional overground walking training for improving spasticity.	1	Morone et al. 2016
2	Functional electrical stimulation of Dorsiflexors and Plantar Flexors with Overground Walking program may not have a difference in efficacy when compared to Overground Walking program for improving spasticity.	1	Embrey et al. 2010

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Overground Walking may not have a difference in efficacy when compared to Treadmill Training for improving range of motion.	2	Bonnyaud et al. 2013a; Bonnyaud et al. 2013b
1b	There is conflicting evidence about the effect of Bent Knee (Prowling) Gait Training when compared to Conventional Therapy for improving range of motion.	1	Dalal et al. 2018
1b	Conventional gait training therapy + Conductive (Petho) methods education may not have a difference in efficacy when compared to Conventional gait training for improving range of motion.	1	Nagy et al. 2017
1b	There is conflicting evidence about the effect of Inclined treadmill training with overground walking when compared to Regular treadmill training with overground walking for improving range of motion.	1	Cheng et al. 2022
2	Overground gait training may not have a difference in efficacy when compared to Treadmill gait training for improving range of motion.	1	Bonnyaud et al. 2013a

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	15cm Stair Height Training with Comprehensive rehabilitation may produce greater improvements in neurophysiological measures than 10cm Stair Height Training with Comprehensive rehabilitation.	1	Yoon-Hee et al. 2020
1b	Curved Gait Training may not have a difference in efficacy when compared to Straight Gait Training for improving neurophysiological measures.	1	Lee et al. 2024b
1b	Outward curved gait training may not have a difference in efficacy when compared to Inward curved gait training for improving neurophysiological measures.	1	Lee et al. 2024b

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	High Intensity Overground Walking may not have a difference in efficacy when compared to Conventional Therapy for improving aerobic measures.	1	Gordon et al. 2013
1b	Step activity monitoring behavioural intervention may not have a difference in efficacy when compared to High-intensity Walking intervention with Step activity monitoring behavioural intervention for improving aerobic measures.	1	Thompson et al. 2024
1b	High-intensity Walking intervention may not have a difference in efficacy when compared to Step activity monitoring behavioural intervention for improving aerobic measures.	1	Thompson et al. 2024
1b	High-intensity Walking intervention may not have a difference in efficacy when compared to High-intensity Walking intervention with Step activity monitoring behavioural intervention for improving aerobic measures.	1	Thompson et al. 2024
2	Intensive locomotor training (body weight supported treadmill with overground walking) may not have a difference in efficacy when compared to No training for improving aerobic measures.	1	Moore et al. 2010

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Treadmill-based with augmented reality may not have a difference in efficacy when compared to Overground walking with physical obstacles for improving activities of daily living.	1	Timmermans et al. 2021
1a	High Intensity Overground Walking may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	2	Shen et al. 2015; Gordon et al. 2013
1b	Community-based gait training may not have a difference in efficacy when compared to conventional training for improving activities of daily living.	1	Lord et al. 2008
1b	There is conflicting evidence about the effect of Backward or Sideway Walking Training when compared to Standing Practice or Conventional Therapy for improving activities of daily living.	2	Huang et al. 2021; Rose et al. 2018
1b	Gait Training with Postural Assistance Support may not have a difference in efficacy when compared to Gait Training with Conventional Support for improving activities of daily living.	1	Dragin et al. 2014
1b	Implicit Motor Learning with Walking may not have a difference in efficacy when compared to Explicit Motor Learning with Walking for improving activities of daily living.	1	Jie et al. 2021
1b	Conventional gait training therapy + Conductive (Petho) methods education may not have a difference in efficacy when compared to Conventional gait training for improving activities of daily living.	1	Nagy et al. 2017
1b	Robot-assisted overground gait training may produce greater improvements in activities of daily living than Conventional rehab.	1	Huo et al. 2024
1b	Overground gait training with Rhythmic auditory stimulation may not have a difference in efficacy when compared to Overground gait training for improving activities of daily living.	1	Osundiya et al. 2023

1b	Overground walking with body weight supported may not have a difference in efficacy when compared to Treadmill training with body weight supported for improving activities of daily living.	1	Gama et al. 2017
1b	Overground walking training with i-Walker robotic assistive device may not have a difference in efficacy when compared to Conventional overground walking training for improving activities of daily living.	1	Morone et al. 2016
1b	Long-term Treadmill and Overground Walking may not have a difference in efficacy when compared to No Intervention for improving activities of daily living.	1	Ada et al. 2013
1b	Long-term Treadmill and Overground Walking may not have a difference in efficacy when compared to Short-term Treadmill and Overground Walking for improving activities of daily living.	1	Ada et al. 2013
2	Overground gait training using E-Go device with Standard Physiotherapy may not have a difference in efficacy when compared to Overground walking training with Standard Physiotherapy for improving activities of daily living.	1	Bizovicar et al. 2017

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Overground Walking may not have a difference in efficacy when compared to Treadmill Training for improving gait speed.	4	Gangopadhyay et al. 2021; Combs-Miller et al. 2014; Bonnyaud et al. 2013a; Bonnyaud et al. 2013b
2	Treadmill-based with augmented reality may not have a difference in efficacy when compared to Overground walking with physical obstacles for improving gait speed.	1	Timmermans et al. 2021
1a	Community-based gait training may produce greater improvements in gait speed than conventional training.	3	Kim et al. 2014d; Park et al. 2011b; Lord et al. 2008
1a	Backward or Sideway Walking Training may produce greater improvements in gait speed than Standing Practice or Conventional Therapy.	5	Huang et al. 2021; Sethy et al. 2021; Kale et al. 2019; Rose et al. 2018; Yang et al. 2005

	intensity home exercise program with Telerehabilitation for improving quality of life.		

Other Associated Outcome Measures

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	15cm Stair Height Training with Comprehensive rehabilitation may produce greater improvements in upper extremity function than 10cm Stair Height Training with Comprehensive rehabilitation.	1	Yoon-Hee et al. 2020
2	Gait training program (treadmill + overground walking) wearing a hip-assist robot may produce greater improvements in upper extremity function than Gait training (treadmill training + over ground walking).	1	Lee et al. 2019a

Key Points

- Overground Walking may be beneficial for improving functional mobility and balance, but not biomechanical gait measures, range of motion, gait speed, gait endurance, and quality of life, after stroke when compared to Treadmill Training.
- Treadmill-based with augmented reality may not be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Overground walking with physical obstacles.
- High Intensity Overground Walking may be beneficial for improving motor recovery and gait endurance, but not muscle strength, aerobic measures, and activities of daily living, after stroke when compared to Conventional Therapy; the literature is mixed regarding quality of life.
- Community-based gait training may be beneficial for improving gait speed, functional mobility, and quality of life, but not activities of daily living and gait endurance, after stroke when compared to conventional training; the literature is mixed regarding falls and fear of falling.
- Bent Knee (Prowling) Gait Training may be beneficial for improving functional mobility after stroke when compared to Conventional Therapy; the literature is mixed regarding range of motion.
- Backward or Sideway Walking Training may be beneficial for improving gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, but not motor recovery, biomechanical gait measures, biomechanical balance measures, and muscle strength, after stroke when compared to Standing Practice or Conventional Therapy; the literature is mixed regarding activities of daily living.
- Lateral Walking Training with Conventional physical therapy may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Backward Walking Training with Conventional physical therapy.
- 15cm Stair Height Training with Comprehensive rehabilitation may be beneficial for improving neurophysiological measures, but not functional mobility and balance, after stroke when compared to 10cm Stair Height Training with Comprehensive rehabilitation.
- Stair or Ramp Training may be beneficial for improving biomechanical balance measures and balance, but not biomechanical gait measures and functional mobility, after stroke when compared to Flat Surface Gait Training; the literature is mixed regarding muscle strength.
- Gait Training with Motor Imagery may be beneficial for improving gait speed and functional mobility after stroke when compared to Conventional Gait Training.
- Gait Training or Overground Walking with Feedback may be beneficial for improving biomechanical gait measures and functional mobility, but not gait speed and gait endurance, after stroke when compared to Without Feedback.
- Gait Training with Postural Assistance Support may be beneficial for improving gait speed and functional mobility, but not motor recovery, activities of daily living, and balance, after stroke when compared to Gait Training with Conventional Support.

- Gait training with Insoles may be beneficial for improving biomechanical balance measures and gait speed, but not biomechanical gait measures and gait endurance, after stroke when compared to Gait training with Conventional Shoes.
- Accurate Adaptability Walking may be beneficial for improving motor recovery, but not gait speed, functional mobility, balance, and falls and fear of falling, after stroke when compared to Steady State Walking.
- Implicit Motor Learning with Walking may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Explicit Motor Learning with Walking.
- Curved Gait Training may be beneficial for improving functional mobility, but not biomechanical gait measures, neurophysiological measures, and gait speed, after stroke when compared to Straight Gait Training.
- Outward curved gait training may not be beneficial for improving biomechanical gait measures, neurophysiological measures, gait speed, and functional mobility after stroke when compared to Inward curved gait training.
- Gait Training on Sand may be beneficial for improving gait speed, but not functional mobility and balance, after stroke when compared to Gait Training on Firm Surface.
- Step activity monitoring behavioural intervention may not be beneficial for improving aerobic measures, gait speed, and gait endurance after stroke when compared to High-intensity Walking intervention with Step activity monitoring behavioural intervention.
- High-intensity Walking intervention may not be beneficial for improving aerobic measures, gait speed, and gait endurance after stroke when compared to Step activity monitoring behavioural intervention.
- High-intensity Walking intervention may not be beneficial for improving aerobic measures, gait speed, and gait endurance after stroke when compared to High-intensity Walking intervention with Step activity monitoring behavioural intervention.
- Conventional gait training therapy + Conductive (Petho) methods education may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, activities of daily living, gait speed, gait endurance, and functional mobility after stroke when compared to Conventional gait training.
- Robot-assisted overground gait training may be beneficial for improving motor recovery, activities of daily living, functional mobility, and balance after stroke when compared to Conventional rehab.
- Overground gait training with Rhythmic auditory stimulation may not be beneficial for improving motor recovery, activities of daily living, gait endurance, and balance after stroke when compared to Overground gait training; the literature is mixed regarding biomechanical gait measures and gait speed.
- Inclined treadmill training with overground walking may be beneficial for improving biomechanical gait measures, but not muscle strength, spasticity, and gait speed, after stroke when compared to Regular treadmill training with overground walking; the literature is mixed regarding range of motion and functional mobility.
- Backward walking observational training & Conventional therapy may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility, and falls and fear of falling after stroke when compared to Landscape observational training (sham) & Conventional therapy.
- Action observation of backward walking may be beneficial for improving functional mobility after stroke when compared to Landscape video with Backward walking training.
- Gait training program (treadmill + overground walking) wearing a hip-assist robot may be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, gait speed, and falls and fear of falling, but not balance, after stroke when compared to Gait training (treadmill training + over ground walking).
- Error Augmentation treadmill training with Overground walking may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Conventional treadmill training with Overground walking.

- Overground walking with body weight supported may not be beneficial for improving motor recovery, biomechanical gait measures, activities of daily living, gait speed, and gait endurance after stroke when compared to Treadmill training with body weight supported.
- Overground walking training with i-Walker robotic assistive device may be beneficial for improving gait speed, gait endurance, and functional mobility, but not motor recovery, spasticity, and activities of daily living, after stroke when compared to Conventional overground walking training.
- Overground gait training may not be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to Treadmill gait training.
- Long-term Treadmill and Overground Walking may be beneficial for improving gait speed, gait endurance, and quality of life, but not activities of daily living, functional mobility, and falls and fear of falling, after stroke when compared to No Intervention; the literature is mixed regarding biomechanical gait measures.
- Long-term Treadmill and Overground Walking may be beneficial for improving gait endurance, but not biomechanical gait measures, activities of daily living, gait speed, and falls and fear of falling, after stroke when compared to Short-term Treadmill and Overground Walking; the literature is mixed regarding functional mobility and quality of life.
- Home-based cycle ergometer exercise may not be beneficial for improving gait speed, gait endurance, balance, and quality of life after stroke when compared to Home-based overground walking exercise.
- Treadmill training with Rehabilitation program may be beneficial for improving gait speed and gait endurance after stroke when compared to Overground gait training with Rehabilitation program; the literature is mixed regarding biomechanical gait measures.
- Intensive locomotor training (body weight supported treadmill with overground walking) may be beneficial for improving gait speed, but not aerobic measures, functional mobility, and balance, after stroke when compared to No training.
- Functional electrical stimulation of Dorsiflexors and Plantar Flexors with Overground Walking program may be beneficial for improving gait endurance and quality of life, but not muscle strength, spasticity, and functional mobility, after stroke when compared to Overground Walking program.
- Gait Trainer GT I (Rehastim) may not be beneficial for improving motor recovery, gait speed, gait endurance, and functional mobility after stroke when compared to Conventional physiotherapy.
- Gait Trainer GT I (Rehastim) may not be beneficial for improving motor recovery, gait speed, gait endurance, and functional mobility after stroke when compared to Overground gait training.
- Treadmill training with overground gait training may be beneficial for improving gait speed and gait endurance, but not quality of life, after stroke when compared to Placebo program of low- intensity home exercise program with Telerehabilitation; the literature is mixed regarding biomechanical gait measures.
- Overground gait training using E-Go device with Standard Physiotherapy may not be beneficial for improving motor recovery, activities of daily living, gait endurance, functional mobility, and balance after stroke when compared to Overground walking training with Standard Physiotherapy.

Summary of Key Points: Non-Technological Overground Walking and Gait Training

Intervention	Control(s)	Function domain(s)	Effect
Overground Walking	Treadmill Training	Functional mobility, balance	+
Overground Walking	Treadmill Training	Biomechanical gait measures, range of motion, gait speed, gait endurance, quality of life	–
Treadmill-based with augmented reality	Overground walking with physical obstacles	Activities of daily living, gait speed, functional mobility	–
High Intensity Overground Walking	Conventional Therapy	Motor recovery, gait endurance	+
High Intensity Overground Walking	Conventional Therapy	Muscle strength, aerobic measures, activities of daily living	–
High Intensity Overground Walking	Conventional Therapy	Quality of life	=

Community-based gait training	conventional training	Gait speed, functional mobility, quality of life	+
Community-based gait training	conventional training	Activities of daily living, gait endurance	–
Community-based gait training	conventional training	Falls and fear of falling	=
Bent Knee (Prowling) Gait Training	Conventional Therapy	Functional mobility	+
Bent Knee (Prowling) Gait Training	Conventional Therapy	Range of motion	=
Backward or Sideway Walking Training	Standing Practice or Conventional Therapy	Gait speed, gait endurance, functional mobility, balance, falls and fear of falling	+
Backward or Sideway Walking Training	Standing Practice or Conventional Therapy	Motor recovery, biomechanical gait measures, biomechanical balance measures, muscle strength	–
Backward or Sideway Walking Training	Standing Practice or Conventional Therapy	Activities of daily living	=
Lateral Walking Training with Conventional physical therapy	Backward Walking Training with Conventional physical therapy	Biomechanical gait measures, gait speed	+
15cm Stair Height Training with Comprehensive rehabilitation	10cm Stair Height Training with Comprehensive rehabilitation	Neurophysiological measures	+
15cm Stair Height Training with Comprehensive rehabilitation	10cm Stair Height Training with Comprehensive rehabilitation	Functional mobility, balance	–
Stair or Ramp Training	Flat Surface Gait Training	Biomechanical balance measures, balance	+
Stair or Ramp Training	Flat Surface Gait Training	Biomechanical gait measures, functional mobility	–
Stair or Ramp Training	Flat Surface Gait Training	Muscle strength	=
Gait Training with Motor Imagery	Conventional Gait Training	Gait speed, functional mobility	+
Gait Training or Overground Walking with Feedback	Without Feedback	Biomechanical gait measures, functional mobility	+
Gait Training or Overground Walking with Feedback	Without Feedback	Gait speed, gait endurance	–
Gait Training with Postural Assistance Support	Gait Training with Conventional Support	Gait speed, functional mobility	+
Gait Training with Postural Assistance Support	Gait Training with Conventional Support	Motor recovery, activities of daily living, balance	–
Gait training with Insoles	Gait training with Conventional Shoes	Biomechanical balance measures, gait speed	+
Gait training with Insoles	Gait training with Conventional Shoes	Biomechanical gait measures, gait endurance	–
Accurate Adaptability Walking	Steady State Walking	Motor recovery	+
Accurate Adaptability Walking	Steady State Walking	Gait speed, functional mobility, balance, falls and fear of falling	–
Implicit Motor Learning with Walking	Explicit Motor Learning with Walking	Activities of daily living, gait speed, functional mobility, quality of life	–

Curved Gait Training	Straight Gait Training	Functional mobility	+
Curved Gait Training	Straight Gait Training	Biomechanical gait measures, neurophysiological measures, gait speed	–
Outward curved gait training	Inward curved gait training	Biomechanical gait measures, neurophysiological measures, gait speed, functional mobility	–
Gait Training on Sand	Gait Training on Firm Surface	Gait speed	+
Gait Training on Sand	Gait Training on Firm Surface	Functional mobility, balance	–
Step activity monitoring behavioural intervention	High-intensity Walking intervention with Step activity monitoring behavioural intervention	Aerobic measures, gait speed, gait endurance	–
High-intensity Walking intervention	Step activity monitoring behavioural intervention	Aerobic measures, gait speed, gait endurance	–
High-intensity Walking intervention	High-intensity Walking intervention with Step activity monitoring behavioural intervention	Aerobic measures, gait speed, gait endurance	–
Conventional gait training therapy + Conductive (Petho) methods education	Conventional gait training	Motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, activities of daily living, gait speed, gait endurance, functional mobility	–
Robot-assisted overground gait training	Conventional rehab	Motor recovery, activities of daily living, functional mobility, balance	+
Overground gait training with Rhythmic auditory stimulation	Overground gait training	Motor recovery, activities of daily living, gait endurance, balance	–
Inclined treadmill training with overground walking	Regular treadmill training with overground walking	Biomechanical gait measures	+
Inclined treadmill training with overground walking	Regular treadmill training with overground walking	Muscle strength, spasticity, gait speed	–
Inclined treadmill training with overground walking	Regular treadmill training with overground walking	Range of motion, functional mobility	=
Backward walking observational training & Conventional therapy	Landscape observational training (sham) & Conventional therapy	Biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility, falls and fear of falling	+
Overground gait training with Rhythmic auditory stimulation	Overground gait training	Gait endurance, balance	–
Action observation of backward walking	Landscape video with Backward walking training	Functional mobility	+
Gait training program (treadmill + overground walking) wearing a hip-assist robot	Gait training (treadmill training + over ground walking)	Motor recovery, biomechanical gait measures, muscle strength, gait speed, falls and fear of falling	+
Gait training program (treadmill + overground walking) wearing a hip-assist robot	Gait training (treadmill training + over ground walking)	Balance	–
Error Augmentation treadmill training with Overground walking	Conventional treadmill training with Overground walking	Biomechanical gait measures, gait speed	–

Overground walking with body weight supported	Treadmill training with body weight supported	Motor recovery, biomechanical gait measures, activities of daily living, gait speed, gait endurance	–
Overground walking training with i-Walker robotic assistive device	Conventional overground walking training	Gait speed, gait endurance, functional mobility	+
Overground walking training with i-Walker robotic assistive device	Conventional overground walking training	Motor recovery, spasticity, activities of daily living	–
Overground gait training	Treadmill gait training	Biomechanical gait measures, range of motion, gait speed	–
Long-term Treadmill and Overground Walking	No Intervention	Gait speed, gait endurance, quality of life	+
Long-term Treadmill and Overground Walking	No Intervention	Activities of daily living, functional mobility, falls and fear of falling	–
Long-term Treadmill and Overground Walking	No Intervention	Biomechanical gait measures	=
Long-term Treadmill and Overground Walking	Short-term Treadmill and Overground Walking	Gait endurance	+
Long-term Treadmill and Overground Walking	Short-term Treadmill and Overground Walking	Biomechanical gait measures, activities of daily living, gait speed, falls and fear of falling	–
Long-term Treadmill and Overground Walking	Short-term Treadmill and Overground Walking	Biomechanical gait measures, activities of daily living, gait speed	–
Home-based cycle ergometer exercise	Home-based overground walking exercise	Gait speed, gait endurance, balance, quality of life	–
Treadmill training with Rehabilitation program	Overground gait training with Rehabilitation program	Gait speed, gait endurance	+
Treadmill training with Rehabilitation program	Overground gait training with Rehabilitation program	Biomechanical gait measures	=
Intensive locomotor training (body weight supported treadmill with overground walking)	No training	Gait speed	+
Intensive locomotor training (body weight supported treadmill with overground walking)	No training	Aerobic measures, functional mobility, balance	–
Functional electrical stimulation of Dorsiflexors and Plantar Flexors with Overground Walking program	Overground Walking program	Gait endurance, quality of life	+
Functional electrical stimulation of Dorsiflexors and Plantar Flexors with Overground Walking program	Overground Walking program	Muscle strength, spasticity, functional mobility	–
Gait Trainer GT I (Rehastim)	Conventional physiotherapy	Motor recovery, gait speed, gait endurance, functional mobility	–
Gait Trainer GT I (Rehastim)	Overground gait training	Motor recovery, gait speed, gait endurance, functional mobility	–
Treadmill training with overground gait training	Placebo program of low- intensity home exercise program with Telerehabilitation	Gait speed, gait endurance	+
Treadmill training with overground gait training	Placebo program of low- intensity home exercise program with Telerehabilitation	Quality of life	–

Treadmill training with overground gait training	Placebo program of low- intensity home exercise program with Telerehabilitation	Biomechanical gait measures	=
Long-term Treadmill and Overground Walking	Short-term Treadmill and Overground Walking	Quality of life, functional mobility	=
Overground gait training with Rhythmic auditory stimulation	Overground gait training	Biomechanical gait measures, gait speed	=
Overground gait training using E-Go device with Standard Physiotherapy	Overground walking training with Standard Physiotherapy	Motor recovery, activities of daily living, gait endurance, functional mobility, balance	–

Cycle Ergometer Training

Adopted from: https://www.verywellfit.com/best-indoor-cycling-bikes-4160109

Use of a cycle ergometer for stationary cycling has been used as a safe form of exercise training in those with challenges in maintaining balance and independent gait (Brown et al., 1997). Cycling shares similar locomotor patterns with walking and is typically used for improving muscle strength, aerobic capacity, and to facilitate muscle control in the lower limbs (Kautz & Brown, 1998; Ozaki et al., 2015; Raasch & Zajac, 1999).

A total of 28 RCTs were found that evaluated cycle ergometer training for lower extremity motor rehabilitation. Fourteen RCTs compared Cycle Ergometer Training with Conventional Therapy (Bharti et al. 2022; Horvath et al. 2022; Hu et al. 2022; da Rosa Pinheiro et al. 2021; Karthiga et al. 2020; Wang et al. 2016a; Kim et al. 2015e; Jin et al. 2013; Jin et al. 2012; Letombe et al. 2010; Katz-leurer et al. 2007; Katz-Leurer et al. 2006; Katz-Leurer et al. 2003; Katz-Leurer et al. 2003). Three RCTs compared Cycle Ergometer Training with Sham or No Treatment (Lund et al. 2018; Sandberg et al. 2016; Potempa et al. 1995). One RCT compared Cycle Ergometer with Stretching (Quaney et al. 2009). One RCT compared In-Bed Cycling with Usual Care (Sandberg et al. 2020). One RCT compared Active Cycling with Education and Coaching with Active Cycling with Education or Passive Mobilization (Vanroy et al. 2017.2020). One RCT compared Cycle Ergometer and Treadmill Training with Conventional Therapy (Toledano-Zarhi et al. 2011). One RCT compared Cycle Ergometer Training with Overground Walking (Fujita et al. 2020). One RCT compared Cycle Ergometer with Sliding Machine (Song et al. 2015). One RCT compared Progressive Resistance Training and Cycling with Sham Progressive Resistance Training and Cycling (Lee et al. 2008). One RCT compared Interlimb Coupling Training with Conventional Therapy (Arya et al. 2020). One RCT compared Cycle Ergometry with VR with Cycle Ergometry (Lee 2019d). One RCT compared EMG-triggered Pedalling Training with Pedalling Training (Lee 2022e). One RCT compared Aerobic Cycling with Aerobic Cycling with Cognitive Training (Yeh et al. 2022).

In addition, 22 RCTs in which cycle ergometer training formed part of a combined or comparative intervention are cross-referenced at the end of Table 8; their primary listings appear in other tables.

The methodological details and results of all 28 RCTs are presented in Table 8.

Table 8. RCTs Evaluating Cycle Ergometer Training for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Cycle Ergometer Training vs Conventional Therapy		
Bharti et al. (2022) RCT (5) Nstart=34 Nend=34 TPS=Acute A vs 0	E: Leg and arm cycle ergometer + conventional rehabilitation C: Conventional rehab Duration: 50min 2x/d, 7 consecutive days	E vs C: POMA(+exp) MI(+exp) Trunk control test(+exp) PASS(+exp)
Horvath et al. (2022) RCT (6) Nstart=37 Nend=35 TPS=Chronic A vs B	E: Aerobic cycling + conventional custom physiotherapy C: Conventional custom physiotherapy Duration: 60min/d, 5d/wk, 4wks	E vs C: VO2PEAK(-) metabolic equivalent(-) Load time(-) HRmax(-) VO2VT(+exp) oxygen uptake(+exp) RER(-) 6MWT(+exp) FIM(no stat) exercise duration (-)
Hu et al. (2022) RCT (3) Nstart=52 Nend=52 TPS=Chronic A vs 0	E: Motomed viva 2 cycling C: Conventional Therapy Duration: 20 min/d, 6d/wk, 8 wks	E vs C: FAC(+exp) 10 meter max walking speed (+exp) FMA (+exp) Nerve growth factor (+exp) Brain-derived neurotrophic factor (+exp) Neurotrophin-3 (+exp)
da Rosa Pinheiro et al. (2021) RCT (6) Nstart=20 Nend=20 TPS=Acute A vs 0	E: Conventional physiotherapy + aerobic cycle ergometer C: Conventional physiotherapy Duration: 40min/d, 5d/wk, for 1wk	E vs C: Lower limb strength Hip flexor (+exp) Knee extensor (+exp) Ankle dorsiflexor (+exp) 10-metre walk test (+exp) Berg Balance Scale (+exp) ICU-Mobility Scale (+exp) Perme Score (+exp)
Karthiga et al. (2020) RCT (3) Nstart=20 Nend=20 TPS=Acute A vs 0	E: Conventional physiotherapy + cycle ergometry training C: Conventional physiotherapy Duration: 1h/d, 15d physiotherapy; 30min/d, 15d cycle ergometry	E vs C: Fugl-Meyer Assessment (+exp) Step Test (+exp) Functional Ambulation Category (+exp)
Wang et al. (2016a) RCT (7) Nstart=42	E: Aerobic training (cycle ergometer) C: Conventional rehabilitation Duration: 40min/d, 3d/wk for 6wks	E vs C: Functional Ambulation Category (+exp) Fugl-Meyer Assessment (+exp)

Nend=34 TPS=Subacute A vs 0		Barthel Index (+exp)
Kim et al. (2015e) RCT (8) Nstart=32 Nend=32 TPS=Chronic A vs 0	E: Cycling exercise + Conventional rehabilitation C: Conventional rehabilitation Duration: 30min/d, 5d/wk for 6wks Cycling	E vs C: 10-Metre Walk Test (+exp) Timed Up & Go Test (+exp) Berg Balance Scale (+exp)
Jin et al. (2013) RCT (4) Nstart=128 Nend=128 TPS=Chronic A vs 0	E: Progressive aerobic cycling training C: Conventional therapy Duration: 40min/d, 5d/wk, for 12wks	E vs C: Peak VO2 (+exp) Systolic blood pressure Resting (-) Peak (-) Diastolic blood pressure Resting (-) Peak (-) Heart rate Resting (+exp) peak (-) Muscle strength paretic knee extension (+exp) non paretic knee extension (+exp) 6-minute walking distance (+exp) Berg Balance Scale (-) Modified Ashworth scale (-)
Jin et al. (2012) RCT (4) Nstart=133 Nend=133 TPS=Chronic A vs 0	E: Aerobic training (cycle ergometer) C: Conventional rehabilitation Duration: 40min/d, 5d/wk for 8wks	E vs C: Peak VO2 (+exp) 6-minute walk distance (+exp) Rivermead Mobility Index (-) knee muscle strength (paretic/non-paretic) (+exp) Berg balance Scale(-) modified Ashworth scale (-)
Letombe et al. (2010) RCT (3) Nstart=18 Nend=18 TPS=Acute A vs 0 Also in Table 9 (Treadmill Training)	E: Aerobic training (cycle ergometer, treadmill, balance) C: Conventional rehabilitation Duration: 40-60min/d, 4d/wk for 4wks	E vs C: Maximal Aerobic Power (+exp) VO2peak (+exp) Test Duration (+exp) Barthel Scale (+exp) Katz ADL Scale (+exp)
Katz-Ieurer et al. (2007) RCT (5) Nstart=64 Nend=64 TPS=Acute A vs 0	E: Leg cycle ergometer training C: Conventional rehabilitation Duration: 10-30min/d, 3-5d/wk, 8wks	E vs C: Heart Rate Variability (-) HR at rest (-) peak workload (+exp) walking distance (-) stairs climbing (+exp) Functional Independence Measure (-)
Katz-Leurer et al. (2006) RCT (6) Nstart=24 Nend=23	E: Leg cycle ergometer + Conventional rehabilitation C: Conventional Rehabilitation	E vs C: Postural Assessment Scale (+exp) Static (+exp) Dynamic (+exp)

TPS=Subacute A vs 0	Duration: 10-30min/d, 5d/wk for 3wks cycling	Fugl-Meyer Assessment Lower Extremity (+exp) Functional Independence Measure Total (-) Motor (+exp)
Katz-Leurer et al. (2003) RCT (5) Nstart=92 Nend=90 TPS=Acute A vs 0	E: Aerobic Leg cycle ergometer + Conventional rehabilitation C: Conventional rehabilitation Duration: 10-20min/d, 5d/wk for 2wks then 30min/d, 3d/wk for 6wks Leg cycle	E vs C: Stress test Max workload (+exp) Heart rate (-) Functional Independence Measure total (-) Stairs climbing (+exp) walking distance (+exp) walking speed (-) Frenchay Activities Index (No stats) light housework (No stats) social outings (No stats) walking outside (No stats)
Cycle Ergometer Training vs Sham or No Treatment		
Lund et al. (2018) RCT (5) Nstart=43 Nend=43 TPS=Chronic A vs B vs 0 Also in Table 21 (Strength and Resistance Training)	E1: Aerobic training on cycle ergometer E2: Resistance training of lower extremities C: Sham training of upper extremities Duration: 3sessions/wk for 12wks	E1 vs E2 vs C: Berg Balance Scale (-) Peak oxygen consumption (No stats) maximal voluntary contractions (No stats) 6 min walking test (-) 10m walk speed (-)
Sandberg et al. (2016) RCT (7) Nstart=56 Nend=56 TPS=Acute A vs 0	E: Aerobic exercise on ergometer cycle C: No treatment Duration: 60min/d, 2d/wk for 12wks	E vs C: Peak work rate (+exp) 6-minute walk test (+exp) Maximum walking speed 10 meters (+exp) timed up and go (+exp) single leg stance right eyes open (+exp) left eyes open (+exp) right eyes closed (+exp) left eyes closed (-) EQ-5D VAS (+exp) SIS recovery (+exp) EQ-5D index (-) SIS participation (-)
Potempa et al. (1995) RCT (5) Nstart=42 Nend=42 TPS=Chronic A vs 0	E: Aerobic training (cycle ergometer) C: Sham exercise (passive range- of-motion) Duration: 30min/d, 3d/wk for 10wks	E vs C: At Rest Fugl-Meyer index (-) heart rate (-) systolic pressure (-) Diastolic pressure (-) Maximal exercise heart rate (-) VO2 (+exp) VCO2 (+exp) VE (+exp) Respiratory exchange ratio (-) Workload (+exp)

		Exercise time (+exp)
Cycle Ergometer vs Stretching		
Quaney et al. (2009) RCT (6) Nstart=40 Nend=38 TPS=Chronic A vs B	E: Aerobic Exercise (progressive resistive stationary bicycle training) C: Stretching Exercise at home Duration: 45min/d, 3d/wk for 8wks	E vs C: Vo2max (+exp) Wisconsin Card Sorting Task (-) Stroop task (-) Trail-making (-) Serial Reaction Timed Task random (-) repeated (+exp) predictive grip force modulation (+exp) Fugl-Meyer sensorimotor test (-) Berg Balance Scale(-) Get Up and Go test (+exp)
In-Bed Cycling vs Usual Care		
Sandberg et al. (2020) RCT (6) Nstart=56 Nend=52 TPS=Acute A vs 0	E: In- Bed cycling + Usual care C: Usual care Duration: 20min/d, 5d/wk for 3wks bed cycling	E vs C: 6-minute walk (-) Modified Rankin Scale (-) Barthel Index (-)
Active Cycling with Education and Coaching vs Active Cycling with Education or Passive Mobilization		
Vanroy et al. (2017) RCT (6) Nstart=59 Nend=53 TPS=Subacute A + B vs A + C vs A + D vs A1 vs A2 vs E	Phase I E: Active Cycling + Education C: Passive mobilization therapy Phase II E1: Active cycling + Coaching E2: Active cycling + non-Coaching E1: after initial phase 30mins/d, 3d/wk, for 9 months, Coached Active Cycling E2: after initial phase 30mins/d, 3d/wk, for 9 months, non-Coached Active Cycling Duration: E1 + E2: 30mins/d, 3d/wk, 3 months Active Cycling interval (week 1-8) to continuous (week 9-12) E1: after initial phase 30mins/d, 3d/wk, 9 months, Coached Active Cycling E2: after initial phase 30mins/d, 3d/wk, 9 months, non-Coached Active Cycling C: 30 min/d, 3d/wk, 3 months	E vs C: Heart rate-rest (-) Heart rate-peak (-) VO2peak (-) Oxygen uptake efficiency slope (-) Respiratory exchange ratio (-) Borg's Rating of Perceived Exertion (-) Maximal isometric knee extension paretic (-) nonparetic (-) Functional Ambulation category (-) 10m Walk test comfortable speed (-) maximum speed (-)
Cycle Ergometer and Treadmill Training vs Conventional Therapy		
Toledano-Zarhi et al. (2011) RCT (6) Nstart=28 Nend=27 TPS=Acute A vs 0 Also in Table 9 (Treadmill Training)	E: Aerobic training (treadmill and cycle ergometer) C: Conventional rehabilitation Duration: 35-55min/d, 3d/wk for 6wks	E vs C: 6min Walk test (-) Stair Climb test ascending (-) descending (-) Four Square step test (-) Physiological parameters blood pressure (-) heart rate (-) metabolic equivalents (-)
Cycle Ergometer Training vs Overground Walking		
Fujita et al. (2020)	E: Cycle ergometer	E vs C:

RCT (8) Nstart=21 Nend=21 TPS=Chronic A vs B	C: Overground walking Duration: 10min/single session	Ankle kinematics (-) Knee Kinematics Knee flexion angle at toe-off (+exp) Peak knee flexion angle during early swing phase (+exp) plantar flexion angle at peak knee flex (+con) plantar flexion velocity at toe-off(+exp) Hip Kinematics peak hip flexion velocity (+exp) electromyographic parameter biceps femoris (+exp) rectus femoris(-) vastus lateralis (-) tibialis anterior (-) medial gastrocnemius (-) soleus (-) Gait Velocity (-) Step length (-) Stride length (-) Cadence (-) single/ double support (-)
Cycle Ergometer vs Sliding Machine		
Song et al. (2015) RCT (4) Nstart=40 Nend=40 TPS=Chronic A1 vs A2	E1: Aerobic training (Ergometer bicycle training) E2: Aerobic training (sliding machine) Duration: 30min/d, 5d/wk for 8wks	E1 vs E2: 10-Metre Walk Test (-) Limit of Stability (+exp)
Progressive Resistance Training and Cycling vs Sham Progressive Resistance Training and Cycling		
Lee et al. (2008) RCT (8) Nstart=52 Nend=48 TPS=Chronic A + B vs A vs C vs 0 Also in Table 21 (Strength and Resistance Training)	E1: Aerobic cycling + progressive resistance training (PRT) E2: Aerobic cycling + sham PRT E3: Sham cycling + PRT C: Sham cycling + Sham PRT Duration: 60min/d, 3d/wk for 10wks	E2/E3 vs C: 6MWT distance (-) endurance-affected (+exp3) Endurance unaffected side (+exp2, +exp3) 10MWT fast speed (-) habitual speed (-) Stair climbing power (+exp3) Peak power output (+exp2, +exp3) Peak heart rate (-) Peak oxygen uptake (+exp2) Treadmill walking physical cost index (+exp2) Treadmill walking oxygen cost (-) 1RM in affected leg (+exp3) 1RM in unaffected leg (+exp3) Power in affected leg (+exp3) Power in unaffected leg (+exp3) SF-36 (-) Ewart self-efficacy walking (+exp3)

		Stair climbing (+exp3) E1 vs C: 6MWT distance (-) endurance-affected (+exp1) Endurance unaffected side (+exp1) 10MWT fast speed (-) habitual speed (+con) Stair climbing power (+exp1) Peak power output (+exp1) Peak heart rate (-) Peak oxygen uptake (+exp1) Treadmill walking physical cost index (+exp1) Treadmill walking oxygen cost (-) 1RM in affected leg (+exp1) 1RM in unaffected leg (+exp1) Power in affected leg (+exp1) Power in unaffected leg (+exp1) SF-36 (-) Ewart self-efficacy walking (-) Stair climbing (-)
Interlimb Coupling Training vs Conventional Therapy		
Arya et al. (2020) RCT (9) Nstart=50 Nend=50 TPS=Chronic A vs 0	E: Interlimb coupling activities (rowing, bicycle ergometer, wall cycle and elliptical machine) C: Conventional rehabilitation Duration: 60min/d, 3d/wk for 8wks	E vs C: Fugl-Meyer Assessment (+exp) FMA-UE (+exp) FMA-LE (+exp) Rivermead Visual Gait Assessment (+exp) Functional Ambulation Classification (+exp) modified Rankin Scale (-)
Cycle Ergometry with VR vs Cycle Ergometry		
Lee (2019d) RCT (7) Nstart=42 Nend=42 TPS=Chronic A + B vs A Also in Table 26 (Virtual Reality)	E: Speed-Interactive Pedaling Training + Virtual Reality C: Pedaling Training Duration: 40 min/d, 5d/wk, for 6wks	E vs C: Fugl-Meyer assessment (+exp) Static sitting balance (+exp) Modified Functional reach test (+exp) trunk impairment scale (+exp) Gait velocity (+exp) Cadence (+exp) Stride time (+exp) Step time (+exp) Stride length (+exp) Step length (+exp)
EMG-triggered Pedalling Training vs Pedalling Training

Duration: 60min/d, 4d/wk for 6wks	Peak torque (-) E1 vs E3 vs E4: Self-selected walking speed (-) Fasting walking speed (-) 6-minute walk test (-) Composite torque (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Cycle Ergometer Training may produce greater improvements in motor recovery than Conventional Therapy.	4	Hu et al. 2022; Karthiga et al. 2020; Wang et al. 2016a; Katz-Leurer et al. 2006
2	Cycle Ergometer Training may not have a difference in efficacy when compared to Sham or No Treatment for improving motor recovery.	1	Potempa et al. 1995
1b	Cycle Ergometer may not have a difference in efficacy when compared to Stretching for improving motor recovery.	1	Quaney et al. 2009
1b	Interlimb Coupling Training may produce greater improvements in motor recovery than Conventional Therapy.	1	Arya et al. 2020
1b	Cycle Ergometry with virtual reality may produce greater improvements in motor recovery than Cycle Ergometry.	1	Lee 2019d
1b	Electromyography-triggered Pedalling Training may produce greater improvements in motor recovery than Pedalling Training.	1	Lee 2022e
1b	Repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise may produce greater improvements in motor recovery than Sham repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise.	1	Wang et al. 2024b
1b	Circuit walking, balance, cycling and strength training (CBCS) may produce greater improvements in motor recovery than Sociocultural intervention (board games, cultural discourse and drama).	1	Nindorera et al. 2023
1b	Brain-computer interface- controlled pedaling training may produce greater improvements in motor recovery than Sham brain-computer interface-controlled pedaling training.	1	Yuan et al. 2021
1b	High-frequency repetitive transcranial magnetic stimulation with Hesed coil during active cycling may produce greater improvements in motor recovery than Sham repetitive transcranial magnetic stimulation during cycling.	1	Chieffo et al. 2021
1b	Protein supplement with Cycle ergometer exercise may produce greater improvements in motor recovery than Carbohydrate supplement with Cycle ergometer exercise.	1	Cheng et al. 2020
2	Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer) may produce greater improvements in motor recovery than Conventional Care.	1	Bustamante Valles et al. 2016

1b	Conventional Rehabilitation with Cycling training and biofeedback may produce greater improvements in motor recovery than Conventional Rehabilitation (CR).	1	Yang et al. 2014
1b	Cycling with functional electrical stimulation may produce greater improvements in motor recovery than Cycling with Sham functional electrical stimulation.	1	Ambrosini et al. 2011
1b	Functional electrical stimulation with Cycling Ergometer and Conventional Care may not have a difference in efficacy when compared to Conventional Care for improving motor recovery.	1	Ferrante et al. 2008

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Cycle Ergometer Training may not have a difference in efficacy when compared to Overground Walking for improving biomechanical gait measures.	1	Fujita et al. 2020
1b	Cycle Ergometry with virtual reality may produce greater improvements in biomechanical gait measures than Cycle Ergometry.	1	Lee 2019d
1b	Electromyography-triggered Pedalling Training may produce greater improvements in biomechanical gait measures than Pedalling Training.	1	Lee 2022e
1b	Repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise may produce greater improvements in biomechanical gait measures than Sham repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise.	1	Wang et al. 2024b
1b	Active cycling with functional electrical stimulation may not have a difference in efficacy when compared to Physiotherapy for improving biomechanical gait measures.	1	Peri et al. 2016

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Aerobic training (Ergometer bicycle training) may produce greater improvements in biomechanical balance measures than Aerobic training (sliding machine).	1	Song et al. 2015
2	Functional electrical stimulation with cycling may not have a difference in efficacy when compared to Cycling for improving biomechanical balance measures.	1	Lo et al. 2012

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Cycle Ergometer Training may produce greater improvements in muscle strength than Conventional Therapy.	2	da Rosa Pinheiro et al. 2021; Jin et al. 2012
2	Cycle Ergometer Training may not have a difference in efficacy when compared to Sham or No Treatment for improving muscle strength.	1	Lund et al. 2018
1b	Active Cycling with Education and Coaching may not have a difference in efficacy when compared to Active Cycling with Education or Passive Mobilization for improving muscle strength.	1	Vanroy et al. 2017
1b	Progressive Resistance Training and Cycling may produce greater improvements in muscle strength than Sham Progressive Resistance Training and Cycling.	1	Lee et al. 2008

2	ExoAtlet exoskeleton exercises with rehabilitation may produce greater improvements in muscle strength than Ortorent MOTO pedal trainer for active-passive training with rehabilitation.	1	Kotov et al. 2021
2	Aerobic training on cycle ergometer may not have a difference in efficacy when compared to Sham training of upper extremities for improving muscle strength.	1	Lund et al. 2018
1b	Cycling with functional electrical stimulation and conventional care may not have a difference in efficacy when compared to Conventional care for improving muscle strength.	1	De Sousa et al. 2016
1b	Active Leg Cycling with functional electrical stimulation (unilaterally on the paretic lower limb) may not have a difference in efficacy when compared to Active Leg Cycling for improving muscle strength.	1	Bauer et al. 2015
1b	Cycling induced by functional electrical stimulation with Conventional Rehabilitation may produce greater improvements in muscle strength than Cycling placebo functional electrical stimulation with Conventional Rehabilitation.	1	Ambrosini et al. 2012
1b	There is conflicting evidence about the effect of Cycling with functional electrical stimulation when compared to Cycling with Sham functional electrical stimulation for improving muscle strength.	2	Ambrosini et al. 2011; Janssen et al. 2008
1b	There is conflicting evidence about the effect of Functional electrical stimulation with Cycling Ergometer and Conventional Care when compared to Conventional Care for improving muscle strength.	1	Ferrante et al. 2008
1b	Body weight supported treadmill with upper extremity ergometry training may not have a difference in efficacy when compared to Resistive leg cycling with upper extremity ergometry training for improving muscle strength.	1	Sullivan et al. 2007
1b	Body weight supported treadmill with upper extremity ergometry training may not have a difference in efficacy when compared to body weight supported treadmill with resistive leg cycling training or body weight supported treadmill with lower extremity progressive resistive exercise for improving muscle strength.	1	Sullivan et al. 2007

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Cycle Ergometer Training may not have a difference in efficacy when compared to Conventional Therapy for improving spasticity.	2	Jin et al. 2013; Jin et al. 2012
2	ExoAtlet exoskeleton exercises with rehabilitation may not have a difference in efficacy when compared to Ortorent MOTO pedal trainer for active-passive training with rehabilitation for improving spasticity.	1	Kotov et al. 2021
1b	Leg cycling with functional electrical stimulation with interval patterns timing may produce greater improvements in spasticity than Leg cycling with functional electrical stimulation with linear patterns timing.	1	Shariat et al. 2021
1b	High-frequency repetitive transcranial magnetic stimulation with Hesed coil during active cycling may produce greater improvements in spasticity than Sham repetitive transcranial magnetic stimulation during cycling.	1	Chieffo et al. 2021
1b	Cycling with functional electrical stimulation and conventional care may not have a difference in efficacy when compared to Conventional care for improving spasticity.	1	De Sousa et al. 2016
1b	Active Leg Cycling with functional electrical stimulation (unilaterally on the paretic lower limb) may not have a difference in efficacy when compared to Active Leg Cycling for improving spasticity.	1	Bauer et al. 2015

1b	Conventional Rehabilitation with Cycling training and biofeedback may produce greater improvements in spasticity than Conventional Rehabilitation (CR).	1	Yang et al. 2014
2	Functional electrical stimulation with cycling may not have a difference in efficacy when compared to Cycling for improving spasticity.	1	Lo et al. 2012

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Cycle Ergometer Training may produce greater improvements in range of motion than Conventional Therapy.	1	Jin et al. 2013
1b	Cycle Ergometer Training may result in lesser improvements in range of motion when compared to Overground Walking.	1	Fujita et al. 2020
1b	Leg cycling with functional electrical stimulation with interval patterns timing may produce greater improvements in range of motion than Leg cycling with functional electrical stimulation with linear patterns timing.	1	Shariat et al. 2021

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Electromyography-triggered Pedalling Training when compared to Pedalling Training for improving neurophysiological measures.	1	Lee 2022e
2	Therapist-supervised in home Cycle ergometer with 30min pedaling may not have a difference in efficacy when compared to No treatment for improving neurophysiological measures.	1	Kautz et al. 2005
1b	High-frequency repetitive transcranial magnetic stimulation with Hesed coil during active cycling may produce greater improvements in neurophysiological measures than Sham repetitive transcranial magnetic stimulation during cycling.	1	Chieffo et al. 2021
1b	Protein supplement with Cycle ergometer exercise may produce greater improvements in neurophysiological measures than Carbohydrate supplement with Cycle ergometer exercise.	1	Cheng et al. 2020

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Cycle Ergometer Training may not have a difference in efficacy when compared to Conventional Therapy for improving aerobic measures.	6	Horvath et al. 2022; Jin et al. 2013; Jin et al. 2012; Letombe et al. 2010; Katz-leurer et al. 2007; Katz-Leurer et al. 2003
1b	There is conflicting evidence about the effect of Cycle Ergometer Training when compared to Sham or No Treatment for improving aerobic measures.	3	Lund et al. 2018; Sandberg et al. 2016; Potempa et al. 1995
1b	Cycle Ergometer may produce greater improvements in aerobic measures than Stretching.	1	Quaney et al. 2009
1b	Active Cycling with Education and Coaching may not have a difference in efficacy when compared to Active Cycling with Education or Passive Mobilization for improving aerobic measures.	1	Vanroy et al. 2017
1b	Cycle Ergometer and Treadmill Training may not have a difference in efficacy when compared to Conventional Therapy for improving aerobic measures.	1	Toledano-Zarhi et al. 2011

1b	There is conflicting evidence about the effect of Progressive Resistance Training and Cycling when compared to Sham Progressive Resistance Training and Cycling for improving aerobic measures.	1	Lee et al. 2008
1b	Protein supplement with Cycle ergometer exercise may produce greater improvements in aerobic measures than Carbohydrate supplement with Cycle ergometer exercise.	1	Cheng et al. 2020
2	Aerobic training on cycle ergometer may not have a difference in efficacy when compared to Sham training of upper extremities for improving aerobic measures.	1	Lund et al. 2018
1b	Active cycling with functional electrical stimulation may produce greater improvements in aerobic measures than Physiotherapy.	1	Peri et al. 2016
1b	Aerobic cycling with progressive resistance training (PRT) may not have a difference in efficacy when compared to Sham cycling with Sham PRT for improving aerobic measures.	1	Lee et al. 2008
2	Cycling with functional electrical stimulation may not have a difference in efficacy when compared to Cycling with Sham functional electrical stimulation for improving aerobic measures.	1	Janssen et al. 2008

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Cycle Ergometer Training may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	6	Horvath et al. 2022; Wang et al. 2016a; Letombe et al. 2010; Katz-leurer et al. 2007; Katz-Leurer et al. 2006; Katz-Leurer et al. 2003
1b	In-Bed Cycling may not have a difference in efficacy when compared to Usual Care for improving activities of daily living.	1	Sandberg et al. 2020
1b	Interlimb Coupling Training may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	1	Arya et al. 2020
1b	Aerobic cycling exercise training may not have a difference in efficacy when compared to Computerized cognitive training or Aerobic exercise with computerized cognitive training for improving activities of daily living.	1	Yeh et al. 2022
2	ExoAtlet exoskeleton exercises with rehabilitation may produce greater improvements in activities of daily living than Ortorent MOTO pedal trainer for active-passive training with rehabilitation.	1	Kotov et al. 2021
1b	Cycling with functional electrical stimulation and conventional care may not have a difference in efficacy when compared to Conventional care for improving activities of daily living.	1	De Sousa et al. 2016
1b	Active cycling with functional electrical stimulation may not have a difference in efficacy when compared to Physiotherapy for improving activities of daily living.	1	Peri et al. 2016

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Cycle Ergometer Training may produce greater improvements in gait speed than Conventional Therapy.	4	Hu et al. 2022; da Rosa Pinheiro et al. 2021; Kim et al. 2015e; Katz-Leurer et al. 2003

1b	There is conflicting evidence about the effect of Cycle Ergometer Training when compared to Sham or No Treatment for improving gait speed.	2	Lund et al. 2018; Sandberg et al. 2016
1b	Active Cycling with Education and Coaching may not have a difference in efficacy when compared to Active Cycling with Education or Passive Mobilization for improving gait speed.	1	Vanroy et al. 2017
1b	Cycle Ergometer Training may produce greater improvements in gait speed than Overground Walking.	1	Fujita et al. 2020
2	Aerobic training (Ergometer bicycle training) may not have a difference in efficacy when compared to Aerobic training (sliding machine) for improving gait speed.	1	Song et al. 2015
1b	There is conflicting evidence about the effect of Progressive Resistance Training and Cycling when compared to Sham Progressive Resistance Training and Cycling for improving gait speed.	1	Lee et al. 2008
1b	Cycle Ergometry with virtual reality may produce greater improvements in gait speed than Cycle Ergometry.	1	Lee 2019d
1b	Electromyography-triggered Pedalling Training may produce greater improvements in gait speed than Pedalling Training.	1	Lee 2022e
1b	Aerobic cycling exercise training may not have a difference in efficacy when compared to Computerized cognitive training or Aerobic exercise with computerized cognitive training for improving gait speed.	1	Yeh et al. 2022
1b	Repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise may produce greater improvements in gait speed than Sham repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise.	1	Wang et al. 2024b
1b	Circuit walking, balance, cycling and strength training (CBCS) may not have a difference in efficacy when compared to Sociocultural intervention (board games, cultural discourse and drama) for improving gait speed.	1	Nindorera et al. 2023
2	ExoAtlet exoskeleton exercises with rehabilitation may produce greater improvements in gait speed than Ortorent MOTO pedal trainer for active-passive training with rehabilitation.	1	Kotov et al. 2021
1b	Leg cycling with functional electrical stimulation with interval patterns timing may not have a difference in efficacy when compared to Leg cycling with functional electrical stimulation with linear patterns timing for improving gait speed.	1	Shariat et al. 2021
1b	High-frequency repetitive transcranial magnetic stimulation with Hesed coil during active cycling may not have a difference in efficacy when compared to Sham repetitive transcranial magnetic stimulation during cycling for improving gait speed.	1	Chieffo et al. 2021

Key Points

- Cycle Ergometer Training may be beneficial for improving motor recovery, muscle strength, range of motion, gait speed, gait endurance, functional mobility, and balance, but not spasticity, aerobic measures, and activities of daily living, after stroke when compared to Conventional Therapy.
- Cycle Ergometer Training may be beneficial for improving functional mobility and balance, but not motor recovery, muscle strength, and quality of life, after stroke when compared to Sham or No Treatment; the literature is mixed regarding aerobic measures, gait speed, and gait endurance.
- Cycle Ergometer may be beneficial for improving aerobic measures and functional mobility, but not motor recovery and balance, after stroke when compared to Stretching.
- In-Bed Cycling may not be beneficial for improving activities of daily living and gait endurance after stroke when compared to Usual Care.
- Active Cycling with Education and Coaching may not be beneficial for improving muscle strength, aerobic measures, gait speed, and functional mobility after stroke when compared to Active Cycling with Education or Passive Mobilization.
- Cycle Ergometer and Treadmill Training may not be beneficial for improving aerobic measures, gait endurance, functional mobility, and balance after stroke when compared to Conventional Therapy.
- Cycle Ergometer Training may be beneficial for improving gait speed, but not biomechanical gait measures, after stroke when compared to Overground Walking; Cycle Ergometer Training may result in lesser improvements in range of motion when compared to Overground Walking.
- Aerobic training (Ergometer bicycle training) may be beneficial for improving biomechanical balance measures, but not gait speed, after stroke when compared to Aerobic training (sliding machine).
- Sham progressive resistance training with Cycling may be beneficial for improving gait endurance after stroke when compared to Sham progressive resistance training with Sham cycling.
- Progressive Resistance Training and Cycling may be beneficial for improving muscle strength and gait endurance, but not quality of life, after stroke when compared to Sham Progressive Resistance Training and Cycling; the literature is mixed regarding aerobic measures, gait speed, and functional mobility.
- Interlimb Coupling Training may be beneficial for improving motor recovery and functional mobility, but not activities of daily living, after stroke when compared to Conventional Therapy.
- Cycle Ergometry with virtual reality may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and balance after stroke when compared to Cycle Ergometry.
- Electromyography-triggered Pedalling Training may be beneficial for improving motor recovery, biomechanical gait measures, and gait speed after stroke when compared to Pedalling Training; the literature is mixed regarding neurophysiological measures.
- Aerobic cycling exercise training may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Computerized cognitive training or Aerobic exercise with computerized cognitive training.
- Therapist-supervised in home Cycle ergometer with 30min pedaling may not be beneficial for improving neurophysiological measures after stroke when compared to No treatment.
- Repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and balance after stroke when compared to Sham repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise.

- Circuit walking, balance, cycling and strength training (CBCS) may be beneficial for improving motor recovery, gait endurance, balance, and quality of life, but not gait speed, after stroke when compared to Sociocultural intervention (board games, cultural discourse and drama).
- Brain-computer interface- controlled pedaling training may be beneficial for improving motor recovery after stroke when compared to Sham brain-computer interface-controlled pedaling training.
- ExoAtlet exoskeleton exercises with rehabilitation may be beneficial for improving muscle strength, activities of daily living, gait speed, and functional mobility, but not spasticity, after stroke when compared to Ortorent MOTO pedal trainer for active-passive training with rehabilitation; the literature is mixed regarding balance.
- Leg cycling with functional electrical stimulation with interval patterns timing may be beneficial for improving spasticity and range of motion, but not gait speed and balance, after stroke when compared to Leg cycling with functional electrical stimulation with linear patterns timing; the literature is mixed regarding functional mobility.
- High-frequency repetitive transcranial magnetic stimulation with Hesed coil during active cycling may be beneficial for improving motor recovery, spasticity, and neurophysiological measures, but not gait speed and gait endurance, after stroke when compared to Sham repetitive transcranial magnetic stimulation during cycling.
- Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not be beneficial for improving gait speed, gait endurance, functional mobility, and quality of life after stroke when compared to Sham Combined aerobic and resistance training with Sham Cognitive training.
- Protein supplement with Cycle ergometer exercise may be beneficial for improving motor recovery, neurophysiological measures, aerobic measures, gait endurance, functional mobility, and balance after stroke when compared to Carbohydrate supplement with Cycle ergometer exercise.
- Aerobic training on cycle ergometer may not be beneficial for improving muscle strength, aerobic measures, gait speed, gait endurance, and balance after stroke when compared to Sham training of upper extremities.
- Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer) may be beneficial for improving motor recovery, but not gait speed, gait endurance, and functional mobility, after stroke when compared to Conventional Care.
- Cycling with functional electrical stimulation and conventional care may not be beneficial for improving muscle strength, spasticity, and activities of daily living after stroke when compared to Conventional care.
- Active cycling with functional electrical stimulation may be beneficial for improving aerobic measures, but not biomechanical gait measures, activities of daily living, gait speed, and gait endurance, after stroke when compared to Physiotherapy.
- Active Leg Cycling with functional electrical stimulation (unilaterally on the paretic lower limb) may be beneficial for improving functional mobility, but not muscle strength and spasticity, after stroke when compared to Active Leg Cycling; Active Leg Cycling with functional electrical stimulation (unilaterally on the paretic lower limb) may result in lesser improvements in gait speed when compared to Active Leg Cycling.
- Conventional Rehabilitation with Cycling training and biofeedback may be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Conventional Rehabilitation (CR).
- Home-based cycle ergometer exercise may not be beneficial for improving gait speed, gait endurance, balance, and quality of life after stroke when compared to Home-based overground walking exercise.
- Functional electrical stimulation with cycling may not be beneficial for improving biomechanical balance measures, spasticity, and gait speed after stroke when compared to Cycling.
- Cycling induced by functional electrical stimulation with Conventional Rehabilitation may be beneficial for improving muscle strength, but not gait speed, after stroke when compared to Cycling placebo functional electrical stimulation with Conventional Rehabilitation.
- Cycling with functional electrical stimulation may be beneficial for improving motor recovery and gait speed, but not aerobic measures, gait endurance, and functional mobility, after stroke when compared to Cycling with Sham functional electrical stimulation; the literature is mixed regarding muscle strength and balance.

- Aerobic cycling with progressive resistance training (PRT) may not be beneficial for improving aerobic measures, gait speed, gait endurance, and quality of life after stroke when compared to Sham cycling with Sham PRT.
- Functional electrical stimulation with Cycling Ergometer and Conventional Care may not be beneficial for improving motor recovery, gait speed, and balance after stroke when compared to Conventional Care; the literature is mixed regarding muscle strength.
- Body weight supported treadmill with upper extremity ergometry training may be beneficial for improving gait speed, but not muscle strength and gait endurance, after stroke when compared to Resistive leg cycling with upper extremity ergometry training.
- Body weight supported treadmill with upper extremity ergometry training may not be beneficial for improving muscle strength, gait speed, and gait endurance after stroke when compared to body weight supported treadmill with resistive leg cycling training or body weight supported treadmill with lower extremity progressive resistive exercise.

Summary of Key Points: Cycle Ergometer Training

Intervention	Control(s)	Function domain(s)	Effect
Cycle Ergometer Training	Conventional Therapy	Motor recovery, muscle strength, range of motion, gait speed, gait endurance, functional mobility, balance	+
Cycle Ergometer Training	Conventional Therapy	Spasticity, aerobic measures, activities of daily living	–
Cycle Ergometer Training	Sham or No Treatment	Functional mobility, balance	+
Cycle Ergometer Training	Sham or No Treatment	Motor recovery, muscle strength, quality of life	–
Cycle Ergometer Training	Sham or No Treatment	Aerobic measures, gait speed, gait endurance	=
Cycle Ergometer	Stretching	Aerobic measures, functional mobility	+
Cycle Ergometer	Stretching	Motor recovery, balance	–
In-Bed Cycling	Usual Care	Activities of daily living, gait endurance	–
Active Cycling with Education and Coaching	Active Cycling with Education or Passive Mobilization	Muscle strength, aerobic measures, gait speed, functional mobility	–
Cycle Ergometer and Treadmill Training	Conventional Therapy	Aerobic measures, gait endurance, functional mobility, balance	–
Cycle Ergometer Training	Overground Walking	Gait speed	+
Cycle Ergometer Training	Overground Walking	Biomechanical gait measures	–
Cycle Ergometer Training	Overground Walking	Range of motion	–
Aerobic training (Ergometer bicycle training)	Aerobic training (sliding machine)	Biomechanical balance measures	+
Aerobic training (Ergometer bicycle training)	Aerobic training (sliding machine)	Gait speed	–
Sham progressive resistance training with Cycling	Sham progressive resistance training with Sham cycling	Gait endurance	+
Progressive Resistance Training and Cycling	Sham Progressive Resistance Training and Cycling	Muscle strength, gait endurance	+

Progressive Resistance Training and Cycling	Sham Progressive Resistance Training and Cycling	Quality of life	–
Progressive Resistance Training and Cycling	Sham Progressive Resistance Training and Cycling	Aerobic measures, gait speed, functional mobility	=
Interlimb Coupling Training	Conventional Therapy	Motor recovery, functional mobility	+
Interlimb Coupling Training	Conventional Therapy	Activities of daily living	–
Cycle Ergometry with virtual reality	Cycle Ergometry	Motor recovery, biomechanical gait measures, gait speed, balance	+
Electromyography-triggered Pedalling Training	Pedalling Training	Motor recovery, biomechanical gait measures, gait speed	+
Electromyography-triggered Pedalling Training	Pedalling Training	Neurophysiological measures	=
Aerobic cycling exercise training	Computerized cognitive training or Aerobic exercise with computerized cognitive training	Activities of daily living, gait speed, functional mobility, quality of life	–
Therapist-supervised in home Cycle ergometer with 30min pedaling	No treatment	Neurophysiological measures	–
Repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise	Sham repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise	Motor recovery, biomechanical gait measures, gait speed, balance	+
Circuit walking, balance, cycling and strength training (CBCS)	Sociocultural intervention (board games, cultural discourse and drama)	Motor recovery, gait endurance, balance, quality of life	+
Circuit walking, balance, cycling and strength training (CBCS)	Sociocultural intervention (board games, cultural discourse and drama)	Gait speed	–
Brain-computer interface- controlled pedaling training	Sham brain-computer interface-controlled pedaling training	Motor recovery	+
ExoAtlet exoskeleton exercises with rehabilitation	Ortorent MOTO pedal trainer for active-passive training with rehabilitation	Muscle strength, activities of daily living, gait speed, functional mobility	+
ExoAtlet exoskeleton exercises with rehabilitation	Ortorent MOTO pedal trainer for active-passive training with rehabilitation	Spasticity	–
ExoAtlet exoskeleton exercises with rehabilitation	Ortorent MOTO pedal trainer for active-passive training with rehabilitation	Balance	=
Leg cycling with functional electrical stimulation with interval patterns timing	Leg cycling with functional electrical stimulation with linear patterns timing	Spasticity, range of motion	+
Leg cycling with functional electrical stimulation with interval patterns timing	Leg cycling with functional electrical stimulation with linear patterns timing	Gait speed, balance	–
Leg cycling with functional electrical stimulation with interval patterns timing	Leg cycling with functional electrical stimulation with linear patterns timing	Functional mobility	=
High-frequency repetitive transcranial magnetic stimulation with Hesed coil during active cycling	Sham repetitive transcranial magnetic stimulation during cycling	Motor recovery, spasticity, neurophysiological measures	+

High-frequency repetitive transcranial magnetic stimulation with Hesed coil during active cycling	Sham repetitive transcranial magnetic stimulation during cycling	Gait speed, gait endurance	–
Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training	Sham Combined aerobic and resistance training with Sham Cognitive training	Gait speed, gait endurance, functional mobility, quality of life	–
Protein supplement with Cycle ergometer exercise	Carbohydrate supplement with Cycle ergometer exercise	Motor recovery, neurophysiological measures, aerobic measures, gait endurance, functional mobility, balance	+
Aerobic training on cycle ergometer	Sham training of upper extremities	Muscle strength, aerobic measures, gait speed, gait endurance, balance	–
Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer)	Conventional Care	Motor recovery	+
Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer)	Conventional Care	Gait speed, gait endurance, functional mobility	–
Cycling with functional electrical stimulation and conventional care	Conventional care	Muscle strength, spasticity, activities of daily living	–
Active cycling with functional electrical stimulation	Physiotherapy	Aerobic measures	+
Active cycling with functional electrical stimulation	Physiotherapy	Biomechanical gait measures, activities of daily living, gait speed, gait endurance	–
Active Leg Cycling with functional electrical stimulation (unilaterally on the paretic lower limb)	Active Leg Cycling	Functional mobility	+
Active Leg Cycling with functional electrical stimulation (unilaterally on the paretic lower limb)	Active Leg Cycling	Muscle strength, spasticity	–
Active Leg Cycling with functional electrical stimulation (unilaterally on the paretic lower limb)	Active Leg Cycling	Gait speed	–
Conventional Rehabilitation with Cycling training and biofeedback	Conventional Rehabilitation (CR)	Motor recovery, spasticity, gait speed, gait endurance	+
Home-based cycle ergometer exercise	Home-based overground walking exercise	Gait speed, gait endurance, balance, quality of life	–
Functional electrical stimulation with cycling	Cycling	Biomechanical balance measures, spasticity, gait speed	–
Cycling induced by functional electrical stimulation with Conventional Rehabilitation	Cycling placebo functional electrical stimulation with Conventional Rehabilitation	Muscle strength	+
Cycling induced by functional electrical stimulation with Conventional Rehabilitation	Cycling placebo functional electrical stimulation with Conventional Rehabilitation	Gait speed	–
Cycling with functional electrical stimulation	Cycling with Sham functional electrical stimulation	Motor recovery, gait speed	+
Aerobic cycling with progressive resistance training (PRT)	Sham cycling with Sham PRT	Aerobic measures, gait speed, gait endurance, quality of life	–
Functional electrical stimulation with Cycling Ergometer and Conventional Care	Conventional Care	Motor recovery, gait speed, balance	–

Functional electrical stimulation with Cycling Ergometer and Conventional Care	Conventional Care	Muscle strength	=
Cycling with functional electrical stimulation	Cycling with Sham functional electrical stimulation	Aerobic measures, gait endurance, functional mobility	–
Body weight supported treadmill with upper extremity ergometry training	Resistive leg cycling with upper extremity ergometry training	Gait speed	+
Body weight supported treadmill with upper extremity ergometry training	Resistive leg cycling with upper extremity ergometry training	Muscle strength, gait endurance	–
Body weight supported treadmill with upper extremity ergometry training	body weight supported treadmill with resistive leg cycling training or body weight supported treadmill with lower extremity progressive resistive exercise	Muscle strength, gait speed, gait endurance	–
Cycling with functional electrical stimulation	Cycling with Sham functional electrical stimulation	Muscle strength, balance	=

Treadmill Training

Adopted from: http://www.ptproductsonline.com/2016/01/accentuate-negative/

Treadmill walking is a common rehabilitation intervention used for patients with walking impairments after stroke. It has been shown to increase the total number of steps taken within a training session as compared to a conventional physiotherapy approach (Hesse et al., 2003). As such, treadmill training can be used to encourage intensive, repetitive, task-specific training, which is suggested to be an ideal form of gait training to optimize lower limb rehabilitation after stroke (French et al., 2016; Langhorne et al., 2009). Body weight support (BWS), provided through a harness above the treadmill, is an increasingly popular approach within rehabilitation programs that

attempts to optimize locomotor-related sensory inputs to all neural regions involved in walking (Charalambous et al., 2013; Hassid et al., 1997; Langhorne et al., 2009).

Treadmill training can also be administered with support from Nordic poles or handrails, and training can be modified through adding additional load, applying a horizontal force, encouraging walking sideways, backwards, or through changing the treadmill surface to make it unstable or inclined. Additionally, speed of the treadmill can be changed to increase or decrease intensity.

A total of 106 RCTs were found that evaluated treadmill training for lower extremity motor rehabilitation. Six RCTs compared Treadmill Training with Conventional Therapy (Hu et al. 2023; Baer et al. 2018; Globas et al. 2012; Kuys et al. 2011; Macko et al. 2005; Laufer et al. 2001). Seven RCTs compared Treadmill Training with Overground Training (Van Bladel et al. 2023; Brauer et al. 2022; Aguiar et al. 2020; Bonnyaud et al. 2014b; Bonnyaud et al. 2013b; Park et al. 2013; Langhammer & Stanghelle 2010). Fifteen RCTs compared BWS Treadmill Training with Conventional Therapy (Tarihci Cakmak et al. 2024; Duran et al. 2023; Banjara et al. 2022; Ramakrishna et al. 2021; Lura et al., 2019; Nave et al. 2019; Sukonthamarn et al. 2019; Mustafaoglu et al. 2018; Takao et al. 2015; Mackay-Lyons et al. 2013; Yang et al. 2010; Yen et al. 2008; Eich et al. 2004; Da Cunha et al. 2002; Teixeira da Cunha Filho et al. 2001). Thirteen RCTs compared BWS Treadmill Training with Overground Walking (Gangopadhyay et al. 2021; Gama et al. 2017; DePaul et al. 2015; Mao et al. 2015; Combs-Miller et al. 2014; Middleton et al. 2014; Hoyer et al. 2012; Ada et al. 2010; Dean et al. 2010; Franceschini et al. 2009; Suputtitada et al. 2004; Nilsson et al. 2001; Kosak & Reding 2000). Five RCTs compared BWS Treadmill Training with Treadmill Training (Calabro et al. 2020; Ullah et al. 2017; Srivastava et al. 2016; Lee et al. 2015f; Visintin et al. 1998). One RCT compared BWS Treadmill Training with Mobility Skills with BWS Treadmill Training (Graham et al. 2018). One RCT evaluated BWS Treadmill Training with Cycle Ergometry or Resistive Training (Sullivan et al. 2007). One RCT compared BWS Treadmill Training with Facilitation Technique with BWS Training with Mechanical Assistance (Yagura et al. 2006). One RCT compared BWS Treadmill Training for Different Durations with Home Exercise (Duncan et al. 2011). Two RCTs compared Treadmill Training with Nordic Poles with Treadmill Training (Kang et al. 2016; Shin et al. 2015). Four RCTs compared Treadmill Training with Load with Treadmill Training without Load or Conventional Therapy (Kim & Yim 2017c; de Lima Gomes et al. 2017; Ribeiro et al. 2017; Park et al. 2014c). Three RCTs compared Treadmill Training with Incline with Treadmill Training with Decline or Level Treadmill Training (Cheng et al. 2022; Gama et al. 2015; Carda et al. 2013). One RCT compared Treadmill Training with Increased Speed with Treadmill Training with Increased Incline (Alipsatici et al. 2020). One RCT compared Constraint Induced Movement with Home Exercise with Treadmill Training (Silva et al. 2017). One RCT compared Treadmill Training with Foot Drop Stimulator with Foot Drop Stimulator (Peishun et al. 2021). Two RCTs compared Perturbation Treadmill Training with Treadmill Training (Krause et al. 2024; Esmaeili et al. 2020). One RCT compared Turning Treadmill Training with Treadmill Training (Chen et al. 2014). One RCT compared Treadmill Training with Mirror Therapy with Treadmill Training (Broderick et al. 2019). One RCT compared Treadmill Training with Proprioceptive Neuromuscular Facilitation with Treadmill Training (Kim & Kang 2018c). One RCT compared BWS Treadmill Training with Proprioceptive Neuromuscular Facilitation (Ribeiro et al. 2013). One RCT compared Treadmill Training with Obstacles with Treadmill Training (Jeong et al. 2016). One RCT compared Treadmill Training on Unstable Surface with Treadmill Training (Bang et al. 2014). One RCT compared Treadmill Training with Handrails with Treadmill Training (Kang et al. 2015). One RCT compared Treadmill Training with Horizontal Force with Treadmill Training (Na et al. 2015). Three RCTs compared Treadmill Training with VR with Other Training (Timmermans et al. 2021; Cho et al. 2014; Cho et al. 2013c). One RCT compared Treadmill Training with Smartphone Application with Treadmill Training (Lee et al. 2017a). One RCT compared Treadmill Training with Visual Deprivation with Treadmill Training (Kim et al. 2014c). Six RCTs compared Backward Treadmill Training with Standard Treadmill or Conventional Rehabilitation (Bansal et al. 2023; Chang et al. 2021; Munari et al. 2020; Kim et al. 2017b; Kim et al. 2014c; Takami et al. 2010). Three RCTs compared Treadmill Training with Overground Training with Home Exercise/ no treatment (Ada et al. 2013; Moore et al. 2010; Ada et al. 2003). Four RCTs compared High Intensity Treadmill Training with Low Intensity Treadmill Training (Munari et al., 2018; Holleran et al. 2015; Ivey et al. 2015; Kuys et al. 2011). One RCT compared Fast Speed Treadmill Training with FES with Self-selected or Fast Speed Treadmill Training (Awad et al. 2016). Five RCTs compared Speed Dependent Treadmill Training with Other Treadmill Training (Van Bladel et al. 2022; Helm et al. 2019; Lau & Mak 2011; Pohl et al. 2002; Sullivan et al. 2002). One RCT compared Speed-dependent Treadmill Training with Task-oriented Training (Sharma et al. 2014). One RCT compared Error Augmentation Treadmill Training with Treadmill Training (Lewek et al. 2018). Two RCTs compared Treadmill Training with Stretching (Serra et al. 2022; Luft et al. 2008). Two RCTs compared Treadmill Training with Orthotic Devices with Treadmill Training (Park et al. 2024b; In et al. 2017). One RCT compared Electromechanical gait trainer with Body weight-supported treadmill training (Werner et al. 2002b). One RCT compared Treadmill Training with Action Observation with Treadmill Training (Bang et al. 2013).

In addition, 63 RCTs in which treadmill training formed part of a combined or comparative intervention are cross-referenced at the end of Table 9; their primary listings appear in other tables.

The methodological details and results of all 106 RCTs are presented in Table 9.

Table 9. RCTs Evaluating Treadmill Training for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Treadmill Training vs Conventional Therapy		
Hu et al. (2023) Feasibility/pilot RCT (7) Nstart=33 Nend=33 TPS=Chronic A1 vs A2 Also in Table 11 (Balance Training)	E: Treadmill gait and balance training + Traditional gait and balance training C: Traditional gait + balance training Duration: 90min/d, 5d/wk, 4wks	E vs C: 5MWT (-) Compensatory stepping test (no stat) TUG (-) FTSTS (-) ABC (-) RPE (no stat) HR (no stat)
Baer et al. (2018) RCT (7) Nstart=77 Nend=69 TPS=Subacute A + B vs B	E: Treadmill Training + normal gait re-education C: Normal gait re-education Duration: minimum of 1 session physiotherapy and 2 sessions gait training/wk for 8wks	E vs C: Rivermead Mobility Index(-) Functional Ambulation Category(-) 10-metre walk(-) 6-minute walk(-) Barthel Index(-) Motor Assessment Scale(-) Stroke Impact Scale(-) Vertical 10-cm Visual Analogue Scale (-) Timed Up and Go (-)
Globas et al. (2012) RCT (7) Nstart=38 Nend=36 TPS=Chronic A vs 0 vs B	E: High intensity Treadmill training C: Conventional therapy C: 1h/d, 1-3d/wk, for 13wks Duration: E: 30-50min, 3x/wk, 13wk; C: 1h/ 1-3x/wk, 13wk	E vs C: VO2 Peak (+exp) 6 minute walk (+exp) 10 metre walk test maximum walking speed (+exp) comfortable walking speed (-) Berg Balance Scale(+exp) 5 chair rise (-) SF-12 physical (-) mental (+exp) Rivermead Mobility Index(+exp)
Kuys et al. (2011) RCT (8) Nstart=30 Nend=28 TPS=Subacute A vs 0	E: High intensity treadmill training + usual physiotherapy C: Conventional rehabilitation Duration: 30min/d, 3d/wk for 6wks	E vs C: 6-Minute Walk Test (+exp) 10-Metre Walk Test (+exp) Walking capacity (-) Walking speed (-) Cadence (-) Step length Paretic (-) Non paretic (-) Angular kinematics of knee (-)

		Angular kinematics of hip (-) Angular kinematics of ankle (-) Walking quality (-)
Macko et al. (2005) RCT (5) Nstart=61 Nend=45 TPS=Chronic A vs 0	E: Treadmill training C: Conventional rehabilitation Duration: 40min/d, 3d/wk for 24wks	E vs C: VO2 peak (+exp) Economy of gait (-) 6-Minute Walk Test (+exp) 30-ft timed walk (-) Walking Impairment Questionnaire Distance (+exp) Speed (-) Stair-climbing (-) Rivermead Mobility Index (-)
Laufer et al. (2001) RCT (6) Nstart=29 Nend=25 TPS=Subacute A vs B	E: Treadmill training + Conventional physical therapy C: Overground gait training + Conventional physical therapy Duration: 8-20min/d, 5d/wk for 3wks	E vs C: Functional Ambulation Category (+exp) Standing Balance Test (-) 10-Meter Walk Test (-) Stride length (+exp) Percentage of Swing (-) percentage of paretic single stance period (+exp) Double stance (-) AT muscular activity (-) gastrocnemius muscular activity (+exp)
Treadmill Training vs Overground Training		
Van Bladel et al. (2023) RCT crossover (4) Nstart=25 Nend=25 TPS=Chronic A vs B Also in Table 26 (Virtual Reality)	E: Selfpaced treadmill walking in VR environment C:Self Placed Overground Platform walking Duration: E: 9 minutes (6 min familrization time + 3 minutes of testing) C: NR	E vs C: Gait speed (+exp) cadence (-) Step Width (+exp) Step length paretic (+exp) non paretic (+exp) Stance phase paretic (+exp) non paretic (+exp) Swing phase paretic (+exp) non paretic (+exp) Double Limb Support (+exp) Single Limb Support paretic (+exp) non-paretic (+exp) Step length symmetry (-) Stance phase symmetry (-) Swing phase symmetry (-)
Brauer et al. (2022) RCT (8) Nstart=119 Nend=108 TPS=Acute A + B vs 0	E: Treadmill training + Self- management education C: Conventional gait training Duration: Experimental group: Treadmill + self management education (30 mins/d, 3ds/wk, 8wks) and usual gait training (30 mins/d, 2ds/wk, 8wks). Control group:	E vs C: 10 meter walk test preferred speed (-) fast speed (-) 6 minute walk test (-) VO2 peak(-) Lipid profile

	Usual gait training (30 mins/d, 2ds/wk, 8wks)	LDL (-) TC (-) HDL (-) C-Reactive protein (-) Hospital axiety and depression scale (-) Ambulatory self-confidence questionnaire (-) Physical activity scale for individuals with disabilities (-) Impact on participation and autonomy (-) EuroQual-5D (-)
Aguiar et al. (2020) RCT (7) Nstart=22 Nend=18 TPS=Chronic A vs B	E: Aerobic Treadmill Training (at 60-80% of heart rate reserve) C: Outdoor Overground Walking (below 40% of heart rate reserve) Duration: 40min, 3d/wk, for 12wks	E vs C: Physical Activity Levels Energy Expenditure (-) Human Activity Profile (-) Time Spent in Low-energy Expenditure Activities (-) Stroke-Specific Quality of Life Scale (-) Stroke Impact Scale (-) 10-Meter Walk Speed Test (-) Incremental Shuttle-Walk Test (-) 6-Minute Walk Distance Test (-) Patient Health Questionnaire 2 and 9 (-) VO2 Peak (-) VO2 Ventilatory Threshold (-)
Bonnyaud et al. (2014b) RCT (7) Nstart=56 Nend=56 TPS=Chronic A vs B	E: Treadmill training C: Overground gait training (on a 50-m-long corridor with turns) Duration: 20min single session	E vs C: Timed Up and Go (-)
Bonnyaud et al. (2013a) RCT (4) Nstart=26 Nend=26 TPS=Chronic A vs B Also in Table 7 (Non-Technological Overground Walking and Gait Training)	E: Overground gait training C: Treadmill gait training Duration: 20min, single session	E vs C: Gait Speed (-) Gait Cadence (-) Single limb support phase paretic (-) non-paretic (-) Step length paretic (-) non-paretic (-) Peak hip flexion/extension (-) Peak knee extension/flexion (-) Peak ankle dorsi/plantar flexion (-) Vertical ground reaction force Total support phase-both sides (-) single support phase-both sides (-) Peak propulsion-both sides (-) Peak braking-both sides (-)
Park et al. (2013b) RCT (4) Nstart=40 Nend=40 TPS=Chronic	E: Treadmill training C: Overground gait training Duration: 60min/d, 5d/wk, for 2wks	E vs C: 10-Metre Walk Test (-) 6-Minute Walk Test (-) Berg Balance Scale (-)

A vs B		
Langhammer & Stanghelle (2010) RCT (8) Nstart=40 Nend=34 TPS=Chronic A vs B Also in Table 7 (Non-Technological Overground Walking and Gait Training)	E1: Treadmill training + Rehabilitation program E2: Overground gait training + Rehabilitation program Duration: 30min/d, 5d/wk, treadmill or overground gait & 3hr & 50min/d, 5d/wk, rehabilitation program	E1 vs E2: 6-minute walk test (+exp) 10-meter walk test (+exp) Stride length right leg (+exp) Stride length left leg (+exp) step width (+exp) cadence (-) pulse at rest (-) pulse in activity (-)
BWS Treadmill Training vs Conventional Therapy		
Tarihci Cakmak et al. (2024) RCT (5) Nstart=33 Nend=30 TPS=Subacute A vs 0	E: Bodyweight-supported treadmill training + Conventional rehab C: Conventional rehab Duration: 60min (30min BWSTT + 30min CT)/d, 5d/wk, 3wks	E vs C: 10MWT comfortable speed (+exp) 10MWT fast (-) 6MWT (-) Tinetti balance (-) gait (-) total (-) TUG (+exp) Rivermead mobility index (-) SS-QOL (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Body weight supported Treadmill Training may produce greater improvements in motor recovery than Conventional Therapy.	2	Yang et al. 2010; Eich et al. 2004
1a	Body weight supported Treadmill Training may not have a difference in efficacy when compared to Overground Walking for improving motor recovery.	4	Gama et al. 2017; Mao et al. 2015; Middleton et al. 2014; Nilsson et al. 2001
1b	Body weight supported Treadmill Training may not have a difference in efficacy when compared to Treadmill Training for improving motor recovery.	1	Srivastava et al. 2016
1b	Body weight supported Treadmill Training with Facilitation Technique may not have a difference in efficacy when compared to body weight supported Training with Mechanical Assistance for improving motor recovery.	1	Yagura et al. 2006
1b	Body weight supported Treadmill Training for Different Durations may not have a difference in efficacy when compared to Home Exercise for improving motor recovery.	1	Duncan et al. 2011
2	Treadmill Training with Load may not have a difference in efficacy when compared to Treadmill Training without Load or Conventional Therapy for improving motor recovery.	1	de Lima Gomes et al. 2017
1b	Treadmill Training with Incline may not have a difference in efficacy when compared to Treadmill Training with Decline or Level Treadmill Training for improving motor recovery.	1	Gama et al. 2015

1b	Treadmill Training with Mirror Therapy may not have a difference in efficacy when compared to Treadmill Training for improving motor recovery.	1	Broderick et al. 2019
1b	Backward Treadmill Training may not have a difference in efficacy when compared to Treadmill or Conventional Rehabilitation for improving motor recovery.	1	Bansal et al. 2023
1b	Treadmill Training with Orthotic Devices may produce greater improvements in motor recovery than Treadmill Training.	1	In et al. 2017
1b	Electromechanical gait trainer therapy with Conventional rehabilitation may not have a difference in efficacy when compared to Body weight-supported treadmill training with Conventional rehabilitation for improving motor recovery.	1	Werner et al. 2002b
2	Overground gait training + visual cue feedback may not have a difference in efficacy when compared to Standard physiotherapy for improving motor recovery.	1	Hollands et al. 2015
1b	Bilateral transcranial direct current stimulation and Treadmill may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Treadmill for improving motor recovery.	1	Wong et al. 2023
1b	Bilateral transcranial direct current stimulation and Treadmill may produce greater improvements in motor recovery than Cathodal transcranial direct current stimulation and Treadmill.	1	Wong et al. 2023
1b	Functional electrical stimulation with treadmill gait training may produce greater improvements in motor recovery than Sham Functional electrical stimulation with treadmill gait training.	1	Lee et al. 2022d
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving motor recovery.	1	Madhavan et al. 2020
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High- intensity speed-based treadmill training for improving motor recovery.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High-intensity speed-based treadmill training for improving motor recovery.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving motor recovery.	1	Madhavan et al. 2020
1b	Treadmill Training with Mirror Therapy may not have a difference in efficacy when compared to Treadmill Training with Sham for improving motor recovery.	1	Broderick et al. 2019

2	Gait training program (treadmill + overground walking) wearing a hip-assist robot may produce greater improvements in motor recovery than Gait training (treadmill training + over ground walking).	1	Lee et al. 2019a
1b	High Frequency repetitive transcranial magnetic stimulation (5Hz) with Treadmill Training may produce greater improvements in motor recovery than Sham repetitive transcranial magnetic stimulation with Treadmill Training.	1	Wang et al. 2019b
1b	Water-based aerobic exercise on a motorized aquatic treadmill with Conventional rehabilitation therapy may not have a difference in efficacy when compared to Aerobic Exercise (by upper and lower body ergometers) with Conventional rehabilitation therapy for improving motor recovery.	1	Lee et al. 2018d
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may produce greater improvements in motor recovery than Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.	1	Park et al. 2018a
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may produce greater improvements in motor recovery than Conventional physical therapy with treadmill training.	1	Park et al. 2018a
1b	Body weight supported treadmill training with anodal transcranial direct current stimulation may not have a difference in efficacy when compared to Body weight supported treadmill training with sham transcranial direct current stimulation for improving motor recovery.	1	Manji et al. 2018
1b	Specialized task oriented locomotor training (includes using Tilt table, limb-load monitor, isokinetic device and treadmill training) with Conventional physiotherapy may not have a difference in efficacy when compared to Conventional physiotherapy for improving motor recovery.	1	Richards et al. 2004
2	Treadmill training with Virtual reality may not have a difference in efficacy when compared to Stepping over real objects on 10m walkway for improving motor recovery.	1	Jaffe et al. 2004
1b	Baseline conventional therapy with Treadmill training with partial body weight supported and Individual physical therapy may not have a difference in efficacy when compared to Baseline conventional therapy with Treadmill training with partial body weight supported for improving motor recovery.	1	Werner et al. 2002a

BIOMECHANICAL GAIT MEASURES

1a	Treadmill Training with virtual reality may produce greater improvements in biomechanical gait measures than Other Training.	2	Cho et al. 2014; Cho et al. 2013c
1b	Treadmill Training with Smartphone Application may produce greater improvements in biomechanical gait measures than Treadmill Training.	1	Lee et al. 2017a
2	There is conflicting evidence about the effect of Treadmill Training with Visual Deprivation when compared to Treadmill Training for improving biomechanical gait measures.	1	Kim et al. 2014a
1a	Backward Treadmill Training may not have a difference in efficacy when compared to Treadmill or Conventional Rehabilitation for improving biomechanical gait measures.	3	Munari et al. 2020; Kim et al. 2017b; Takami et al. 2010
2	Body weight supported, backward and forward treadmill training may not have a difference in efficacy when compared to body weight supported, forward treadmill training or body weight supported, backward treadmill training for improving biomechanical gait measures.	1	Kim et al. 2014c

2	Backward treadmill with partial body weight supported may not have a difference in efficacy when compared to Forward treadmill with partial body weight supported treadmill for improving biomechanical gait measures.	1	Takami et al. 2010
2	Forward treadmill with partial BWS treadmill may not have a difference in efficacy when compared to Conventional rehabilitation for improving biomechanical gait measures.	1	Takami et al. 2010
1a	Treadmill Training with Overground Training may not have a difference in efficacy when compared to Home Exercise/ no treatment for improving biomechanical gait measures.	2	Ada et al. 2013; Ada et al. 2003
1b	Long-term Treadmill and Overground Walking may not have a difference in efficacy when compared to Short-term Treadmill and Overground Walking for improving biomechanical gait measures.	1	Ada et al. 2013
1b	High Intensity Treadmill Training may produce greater improvements in biomechanical gait measures than Low Intensity Treadmill Training.	1	Munari et al. 2018
1a	Speed Dependent Treadmill Training may produce greater improvements in biomechanical gait measures than Other Treadmill Training.	4	Van Bladel et al. 2022; Helm et al. 2019; Lau & Mak 2011; Pohl et al. 2002
2	Error Augmentation Treadmill Training may not have a difference in efficacy when compared to Treadmill Training for improving biomechanical gait measures.	1	Lewek et al. 2018
1b	Treadmill Training with Orthotic Devices may produce greater improvements in biomechanical gait measures than Treadmill Training.	1	Park et al. 2024b
1b	Treadmill Training with Action Observation may produce greater improvements in biomechanical gait measures than Treadmill Training.	1	Bang et al. 2013
1b	Circular treadmill training with ambulation training may produce greater improvements in biomechanical gait measures than Regular treadmill training+ ambulation training.	1	Chen et al. 2019b
2	Overground gait training + visual cue feedback may not have a difference in efficacy when compared to Standard physiotherapy for improving biomechanical gait measures.	1	Hollands et al. 2015
1b	There is conflicting evidence about the effect of Rhythmic Auditory Stimulation with Custom Physiotherapy program and Treadmill gait training when compared to Custom physiotherapy program with Treadmill gait training for improving biomechanical gait measures.	1	Ahmed et al. 2023
2	There is conflicting evidence about the effect of Treadmill training with HEALBOT exoskeleton when compared to Treadmill training for improving biomechanical gait measures.	1	Yoo et al. 2023a
1b	Anodal transcranial direct current stimulation with Treadmill training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Treadmill training for improving biomechanical gait measures.	1	Dumont et al. 2023
1b	Bilateral transcranial direct current stimulation and Treadmill may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Treadmill for improving biomechanical gait measures.	1	Wong et al. 2023
1b	Bilateral transcranial direct current stimulation and Treadmill may produce greater improvements in biomechanical gait measures than Cathodal transcranial direct current stimulation and Treadmill.	1	Wong et al. 2023
1b	Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not have a	1	Wang et al. 2022c

	difference in efficacy when compared to Sham taping with exercise training for improving biomechanical gait measures.		
1b	Underwater Treadmill gait training with conventional rehabilitation may not have a difference in efficacy when compared to Overground gait training with conventional rehabilitation for improving biomechanical gait measures.	1	Kim et al. 2022a
1b	Functional electrical stimulation with treadmill gait training may produce greater improvements in biomechanical gait measures than Sham Functional electrical stimulation with treadmill gait training.	1	Lee et al. 2022d
1b	Body weight supported treadmill training (BWST) with conventional rehabilitation may produce greater improvements in biomechanical gait measures than Overground gait training with conventional rehabilitation.	1	Gangopadhyay et al. 2021
1b	Dual-task gait training with treadmill may not have a difference in efficacy when compared to Single-task gait training with treadmill for improving biomechanical gait measures.	1	Baek et al. 2021
2	Treadmill training using insole on less affected side may produce greater improvements in biomechanical gait measures than Treadmill training.	1	An et al. 2020
1b	Gait training with Gait Exercise Assist Robot (GEAR) may not have a difference in efficacy when compared to Gait training with treadmill for improving biomechanical gait measures.	1	Ogino et al. 2020
1b	Cerebellar transcranial direct current stimulation with split-belt treadmill training may not have a difference in efficacy when compared to Sham cerebellar transcranial direct current stimulation with split-belt treadmill training for improving biomechanical gait measures.	1	Kumari et al. 2020
1b	Backward treadmill training with botulinum toxin type A therapy may not have a difference in efficacy when compared to forward treadmill training with botulinum toxin type A therapy for improving biomechanical gait measures.	1	Munari et al. 2020
2	Gait training program (treadmill + overground walking) wearing a hip-assist robot may produce greater improvements in biomechanical gait measures than Gait training (treadmill training + over ground walking).	1	Lee et al. 2019a
1b	Body weight support treadmill training with visual biofeedback may not have a difference in efficacy when compared to Body weight support treadmill training for improving biomechanical gait measures.	1	Druzbicki et al. 2018
1b	Rhythmic auditory stimulation with treadmill training and conventional physical therapy may not have a difference in efficacy when compared to Treadmill training with conventional physical therapy for improving biomechanical gait measures.	1	Mainka et al. 2018
1b	There is conflicting evidence about the effect of Rhythmic auditory stimulation with treadmill training and conventional physical therapy when compared to Neurodevelopmental treatment with conventional physical therapy for improving biomechanical gait measures.	1	Mainka et al. 2018
1b	Whole body vibration with Treadmill training may produce greater improvements in biomechanical gait measures than Exercises on platform without vibration with Treadmill training.	1	Choi et al. 2017b
1b	There is conflicting evidence about the effect of High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc) when compared to Conventional physical therapy care for improving biomechanical gait measures.	1	Hornby et al. 2016

1b	Treadmill training with visual biofeedback and physiotherapy exercises may not have a difference in efficacy when compared to Treadmill training with physiotherapy exercises for improving biomechanical gait measures.	1	Druzbicki et al. 2016a
2	Treadmill training with Rhythmic auditory stimulation may produce greater improvements in biomechanical gait measures than Treadmill training.	1	Song & Ryu 2016
1b	Treadmill training with Rhythmic auditory feedback may produce greater improvements in biomechanical gait measures than Treadmill training.	1	Yang et al. 2016
2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in biomechanical gait measures than Treadmill training.	1	Yoon & Kang 2016
2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in biomechanical gait measures than Inclined treadmill training.	1	Yoon & Kang 2016
2	There is conflicting evidence about the effect of Inclined treadmill training when compared to Treadmill training for improving biomechanical gait measures.	1	Yoon & Kang 2016
1b	Virtual reality treadmill training-based community ambulation may not have a difference in efficacy when compared to Community ambulation training for improving biomechanical gait measures.	1	Kim et al. 2016c
1b	Virtual reality treadmill training-based community ambulation may not have a difference in efficacy when compared to Conventional rehabilitation for improving biomechanical gait measures.	1	Kim et al. 2016c
2	Treadmill training with Virtual reality and Ankle robotics may not have a difference in efficacy when compared to Seated training with Virtual reality and Ankle robotics for improving biomechanical gait measures.	1	Forrester et al. 2016
2	Task-oriented treadmill training with conventional therapy may produce greater improvements in biomechanical gait measures than Treadmill training with conventional therapy.	1	Kwon et al. 2015
1b	Partial body-weight support treadmill training with Visual biofeedback may not have a difference in efficacy when compared to Partial body-weight support treadmill training for improving biomechanical gait measures.	1	Brasileiro et al. 2015
1b	Treadmill training with visual biofeedback and basic physiotherapy may not have a difference in efficacy when compared to Treadmill training with basic physiotherapy for improving biomechanical gait measures.	1	Druzbicki et al. 2015
2	There is conflicting evidence about the effect of Treadmill training with Rhythmic auditory stimulation when compared to Overground training with Rhythmic auditory stimulation for improving biomechanical gait measures.	1	Park et al. 2015a
1b	There is conflicting evidence about the effect of Treadmill training with functional electrical stimulation on gluteus medius and tibialis anterior when compared to Treadmill training for improving biomechanical gait measures.	1	Cho et al. 2015c
2	Overground gait training with ankle mass may not have a difference in efficacy when compared to Overground gait training without mass or Treadmill gait training without mass for improving biomechanical gait measures.	1	Bonnyaud et al. 2013b
1b	Body Weight-Supported Treadmill Training with functional electrical stimulation may produce greater improvements in biomechanical gait measures than Body Weight Supported Treadmill Training.	1	Lee et al. 2013g

2	Underwater treadmill walking may produce greater improvements in biomechanical gait measures than Overground treadmill walking.	1	Park et al. 2012
2	Treadmill training with Virtual reality and Conventional rehabilitation may not have a difference in efficacy when compared to Treadmill training with Conventional rehabilitation for improving biomechanical gait measures.	1	Yang et al. 2011
2	Treadmill training with Virtual reality may not have a difference in efficacy when compared to Stepping over real objects on 10m walkway for improving biomechanical gait measures.	1	Jaffe et al. 2004
1b	There is conflicting evidence about the effect of Treadmill training and overground gait training when compared to Placebo program of low- intensity home exercise program with Telerehabilitation for improving biomechanical gait measures.	1	Ada et al. 2003

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Treadmill Training with Load may not have a difference in efficacy when compared to Treadmill Training without Load or Conventional Therapy for improving biomechanical balance measures.	1	Park et al. 2014c
1b	Turning Treadmill Training may not have a difference in efficacy when compared to Treadmill Training for improving biomechanical balance measures.	1	Chen et al. 2014
1b	Treadmill Training with virtual reality may not have a difference in efficacy when compared to Other Training for improving biomechanical balance measures.	1	Cho et al. 2014
1b	Backward Treadmill Training may produce greater improvements in biomechanical balance measures than Treadmill or Conventional Rehabilitation.	1	Munari et al. 2020
1b	Backward treadmill training with botulinum toxin type A therapy may produce greater improvements in biomechanical balance measures than forward treadmill training with botulinum toxin type A therapy.	1	Munari et al. 2020
1b	Rhythmic auditory stimulation with treadmill training and conventional physical therapy may not have a difference in efficacy when compared to Treadmill training with conventional physical therapy for improving biomechanical balance measures.	1	Mainka et al. 2018
1b	Rhythmic auditory stimulation with treadmill training and conventional physical therapy may not have a difference in efficacy when compared to Neurodevelopmental treatment with conventional physical therapy for improving biomechanical balance measures.	1	Mainka et al. 2018
1b	Treadmill training with Gait Trainer 2 Biodex biofeedback (30-45min/d) with Conventional individual exercises may not have a difference in efficacy when compared to Treadmill training without biofeedback with Conventional individual exercises for improving biomechanical balance measures.	1	Druzbicki et al. 2016b
2	Treadmill training with Virtual reality and Ankle robotics may not have a difference in efficacy when compared to Seated training with Virtual reality and Ankle robotics for improving biomechanical balance measures.	1	Forrester et al. 2016
2	Treadmill training with Virtual reality may produce greater improvements in biomechanical balance measures than Conventional rehabilitation.	1	Kim et al. 2015a
2	Treadmill training with Virtual reality and Conventional rehabilitation may not have a difference in efficacy when compared to Treadmill	1	Yang et al. 2011

	training with Conventional rehabilitation for improving biomechanical balance measures.		

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Body weight supported Treadmill Training may not have a difference in efficacy when compared to Conventional Therapy for improving muscle strength.	2	Nave et al. 2019; Sukonthamarn et al. 2019
1b	Body weight supported Treadmill Training may not have a difference in efficacy when compared to Overground Walking for improving muscle strength.	1	Franceschini et al. 2009
1b	Body weight supported treadmill with upper extremity ergometry training may not have a difference in efficacy when compared to Resistive leg cycling with upper extremity ergometry training for improving muscle strength.	1	Sullivan et al. 2007
1b	Body weight supported treadmill with upper extremity ergometry training may not have a difference in efficacy when compared to body weight supported treadmill with resistive leg cycling training or body weight supported treadmill with lower extremity progressive resistive exercise for improving muscle strength.	1	Sullivan et al. 2007
1b	Treadmill Training with Incline may not have a difference in efficacy when compared to Treadmill Training with Decline or Level Treadmill Training for improving muscle strength.	1	Cheng et al. 2022
1b	Perturbation Treadmill Training may not have a difference in efficacy when compared to Treadmill Training for improving muscle strength.	1	Esmaeili et al. 2020
1b	Turning Treadmill Training may produce greater improvements in muscle strength than Treadmill Training.	1	Chen et al. 2014
2	Gait training program (treadmill + overground walking) wearing a hip-assist robot may produce greater improvements in muscle strength than Gait training (treadmill training + over ground walking).	1	Lee et al. 2019a
1b	There is conflicting evidence about the effect of Water-based aerobic exercise on a motorized aquatic treadmill with Conventional rehabilitation therapy when compared to Aerobic Exercise (by upper and lower body ergometers) with Conventional rehabilitation therapy for improving muscle strength.	1	Lee et al. 2018d
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may produce greater improvements in muscle strength than Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.	1	Park et al. 2018a
1b	Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy or Auditory stimulation with robot-assisted gait training (Treadmill) with conventional physical therapy may produce greater improvements in muscle strength than Conventional physical therapy with treadmill training.	1	Park et al. 2018a
1b	There is conflicting evidence about the effect of Aquatic therapy (physical therapy exercises) with aquatic treadmill when compared to Conventional physical therapy exercise with land-based treadmill for improving muscle strength.	1	Zhang et al. 2016
1b	There is conflicting evidence about the effect of Treadmill training with functional electrical stimulation on gluteus medius and tibialis anterior when compared to Treadmill training for improving muscle strength.	1	Cho et al. 2015c
1b	Treadmill training with Tilt sensor functional electrical stimulation with conventional physical therapy may not have a difference in	1	Hwang et al. 2015

	efficacy when compared to Treadmill training with Placebo Tilt sensor functional electrical stimulation with conventional physical therapy for improving muscle strength.		

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Body weight supported Treadmill Training may not have a difference in efficacy when compared to Overground Walking for improving spasticity.	1	Franceschini et al. 2009

2	Treadmill Training on Unstable Surface may not have a difference in efficacy when compared to Treadmill Training for improving gait speed.	1	Bang et al. 2014
2	Treadmill Training with Horizontal Force may produce greater improvements in gait speed than Treadmill Training.	1	Na et al. 2015
2	Treadmill-based C-Mill (using gait-dependent augmented reality) may not have a difference in efficacy when compared to Overground walking therapy (walking-adaptability exercises with physical obstacles) for improving gait speed.	1	Timmermans et al. 2021
1a	Treadmill Training with virtual reality may produce greater improvements in gait speed than Other Training.	2	Cho et al. 2014; Cho et al. 2013c

1b	Treadmill Training with Smartphone Application may produce greater improvements in gait speed than Treadmill Training.	1	Lee et al. 2017a
2	Treadmill Training with Visual Deprivation may produce greater improvements in gait speed than Treadmill Training.	1	Kim et al. 2014a
1a	Backward Treadmill Training may not have a difference in efficacy when compared to Treadmill or Conventional Rehabilitation for improving gait speed.	5	Bansal et al. 2023; Chang et al. 2021; Munari et al. 2020; Kim et al. 2017b; Takami et al. 2010
2	Backward treadmill with partial body weight supported may not have a difference in efficacy when compared to Forward treadmill with partial body weight supported treadmill for improving gait speed.	1	Takami et al. 2010
2	Forward treadmill with partial BWS treadmill may not have a difference in efficacy when compared to Conventional rehabilitation for improving gait speed.	1	Takami et al. 2010
1a	Treadmill Training with Overground Training may produce greater improvements in gait speed than Home Exercise/ no treatment.	3	Ada et al. 2013; Moore et al. 2010; Ada et al. 2003
1b	Long-term Treadmill and Overground Walking may not have a difference in efficacy when compared to Short-term Treadmill and Overground Walking for improving gait speed.	1	Ada et al. 2013
1b	High Intensity Treadmill Training may not have a difference in efficacy when compared to Low Intensity Treadmill Training for improving gait speed.	2	Munari et al. 2018; Holleran et al. 2015
1b	Fast Speed Treadmill Training with functional electrical stimulation may produce greater improvements in gait speed than Self-selected or Fast Speed Treadmill Training.	1	Awad et al. 2016
1a	Speed Dependent Treadmill Training may produce greater improvements in gait speed than Other Treadmill Training.	3	Van Bladel et al. 2022; Lau & Mak 2011; Pohl et al. 2002
2	Body weight supported treadmill training (fast speed) may result in lesser improvements in gait speed when compared to body weight supported treadmill training (slow speed) or body weight supported treadmill training (variable speed).	1	Sullivan et al. 2002
2	Error Augmentation Treadmill Training may not have a difference in efficacy when compared to Treadmill Training for improving gait speed.	1	Lewek et al. 2018
2	Treadmill Training may not have a difference in efficacy when compared to Stretching for improving gait speed.	2	Serra et al. 2022; Luft et al. 2008
1a	Treadmill Training with Orthotic Devices may produce greater improvements in gait speed than Treadmill Training.	2	Park et al. 2024b; In et al. 2017
1b	Electromechanical gait trainer therapy with Conventional rehabilitation may not have a difference in efficacy when compared to Body weight-supported treadmill training with Conventional rehabilitation for improving gait speed.	1	Werner et al. 2002b
1b	Treadmill Training with Action Observation may produce greater improvements in gait speed than Treadmill Training.	1	Bang et al. 2013
1b	Circular treadmill training with ambulation training may produce greater improvements in gait speed than Regular treadmill training+ ambulation training.	1	Chen et al. 2019b
2	Overground gait training + visual cue feedback may not have a difference in efficacy when compared to Standard physiotherapy for improving gait speed.	1	Hollands et al. 2015
2	Treadmill walking training + conventional PT may not have a difference in efficacy when compared to conventional PT for improving gait speed.	1	Olawale et al. 2011

1b	There is conflicting evidence about the effect of Augmented reality treadmill-based gait adaptation training when compared to Treadmill training with overground walking for improving gait speed.	1	Yang et al. 2024a
1b	Rhythmic Auditory Stimulation with Custom Physiotherapy program and Treadmill gait training may produce greater improvements in gait speed than Custom physiotherapy program with Treadmill gait training.	1	Ahmed et al. 2023
2	There is conflicting evidence about the effect of Treadmill training with HEALBOT exoskeleton when compared to Treadmill training for improving gait speed.	1	Yoo et al. 2023a
2	Functional electrical stimulation with treadmill training may not have a difference in efficacy when compared to Treadmill training for improving gait speed.	1	Dantas et al. 2023
1b	Anodal transcranial direct current stimulation with Treadmill training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Treadmill training for improving gait speed.	1	Dumont et al. 2023
1b	Bilateral transcranial direct current stimulation and Treadmill may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Treadmill for improving gait speed.	1	Wong et al. 2023
1b	Bilateral transcranial direct current stimulation and Treadmill may produce greater improvements in gait speed than Cathodal transcranial direct current stimulation and Treadmill.	1	Wong et al. 2023
1b	Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not have a difference in efficacy when compared to Sham taping with exercise training for improving gait speed.	1	Wang et al. 2022c
1b	There is conflicting evidence about the effect of Underwater Treadmill gait training with conventional rehabilitation when compared to Overground gait training with conventional rehabilitation for improving gait speed.	1	Kim et al. 2022a
1b	Functional electrical stimulation with treadmill gait training may produce greater improvements in gait speed than Sham Functional electrical stimulation with treadmill gait training.	1	Lee et al. 2022d
1b	Body weight supported treadmill training (BWST) with conventional rehabilitation may produce greater improvements in gait speed than Overground gait training with conventional rehabilitation.	1	Gangopadhyay et al. 2021
1b	Dual-task gait training with treadmill may produce greater improvements in gait speed than Single-task gait training with treadmill.	1	Baek et al. 2021
2	Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not have a difference in efficacy when compared to Sham Combined aerobic and resistance training with Sham Cognitive training for improving gait speed.	1	Koch et al. 2020
2	Treadmill training using insole on less affected side may produce greater improvements in gait speed than Treadmill training.	1	An et al. 2020
1b	Gait training with Gait Exercise Assist Robot (GEAR) may not have a difference in efficacy when compared to Gait training with treadmill for improving gait speed.	1	Ogino et al. 2020
1b	High frequency repetitive transcranial magnetic stimulation with Treadmill Training may produce greater improvements in gait speed than Sham repetitive transcranial magnetic stimulation with Treadmill Training.	1	Lee et al. 2020a

1b	Cerebellar transcranial direct current stimulation with split-belt treadmill training may not have a difference in efficacy when compared to Sham cerebellar transcranial direct current stimulation with split-belt treadmill training for improving gait speed.	1	Kumari et al. 2020
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving gait speed.	1	Madhavan et al. 2020
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High- intensity speed-based treadmill training for improving gait speed.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High-intensity speed-based treadmill training for improving gait speed.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving gait speed.	1	Madhavan et al. 2020
1b	Backward treadmill training with botulinum toxin type A therapy may produce greater improvements in gait speed than forward treadmill training with botulinum toxin type A therapy.	1	Munari et al. 2020
2	There is conflicting evidence about the effect of High-Intensity Interval Training – Treadmill when compared to Moderate-intensity Continuous Exercise - Treadmill for improving gait speed.	1	Boyne et al. 2019
1b	Dual-task (virtual reality-based UL training while walking on treadmill) may produce greater improvements in gait speed than Single task treadmill walking.	1	Fishbein et al. 2019
1b	Treadmill Training with Mirror Therapy may not have a difference in efficacy when compared to Treadmill Training with Sham for improving gait speed.	1	Broderick et al. 2019
2	Gait training program (treadmill + overground walking) wearing a hip-assist robot may produce greater improvements in gait speed than Gait training (treadmill training + over ground walking).	1	Lee et al. 2019a
2	Hybrid Assistive Limb (HAL) exoskeleton with Bodyweight supported treadmill training may not have a difference in efficacy when compared to Conventional Physical therapy for improving gait speed.	1	Sczesny-Kaiser et al. 2019
1b	High Frequency repetitive transcranial magnetic stimulation (5Hz) with Treadmill Training may produce greater improvements in gait speed than Sham repetitive transcranial magnetic stimulation with Treadmill Training.	1	Wang et al. 2019b
1b	There is conflicting evidence about the effect of Body weight support treadmill training with visual biofeedback when compared to Body weight support treadmill training for improving gait speed.	1	Druzbicki et al. 2018

1b	There is conflicting evidence about the effect of Rhythmic auditory stimulation with treadmill training and conventional physical therapy when compared to Treadmill training with conventional physical therapy for improving gait speed.	1	Mainka et al. 2018
1b	There is conflicting evidence about the effect of Rhythmic auditory stimulation with treadmill training and conventional physical therapy when compared to Neurodevelopmental treatment with conventional physical therapy for improving gait speed.	1	Mainka et al. 2018
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may not have a difference in efficacy when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy for improving gait speed.	1	Park et al. 2018a
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may produce greater improvements in gait speed than Conventional physical therapy with treadmill training.	1	Park et al. 2018a
1b	Body weight supported treadmill training with anodal transcranial direct current stimulation may produce greater improvements in gait speed than Body weight supported treadmill training with sham transcranial direct current stimulation.	1	Manji et al. 2018
1b	Whole body vibration with Treadmill training may produce greater improvements in gait speed than Exercises on platform without vibration with Treadmill training.	1	Choi et al. 2017b
1b	High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc) may produce greater improvements in gait speed than Conventional physical therapy care.	1	Hornby et al. 2016
2	Treadmill training with Rhythmic auditory stimulation may produce greater improvements in gait speed than Treadmill training.	1	Song & Ryu 2016
1b	Treadmill training with Rhythmic auditory feedback may produce greater improvements in gait speed than Treadmill training.	1	Yang et al. 2016
2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in gait speed than Treadmill training.	1	Yoon & Kang 2016
2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in gait speed than Inclined treadmill training.	1	Yoon & Kang 2016
2	Inclined treadmill training may produce greater improvements in gait speed than Treadmill training.	1	Yoon & Kang 2016
1b	Virtual reality treadmill training-based community ambulation may not have a difference in efficacy when compared to Community ambulation training for improving gait speed.	1	Kim et al. 2016c
1b	Virtual reality treadmill training-based community ambulation may not have a difference in efficacy when compared to Conventional rehabilitation for improving gait speed.	1	Kim et al. 2016c
2	Treadmill training with Virtual reality and Ankle robotics may not have a difference in efficacy when compared to Seated training with Virtual reality and Ankle robotics for improving gait speed.	1	Forrester et al. 2016
2	Task-oriented treadmill training with conventional therapy may produce greater improvements in gait speed than Treadmill training with conventional therapy.	1	Kwon et al. 2015
1b	Treadmill training with visual biofeedback and basic physiotherapy may not have a difference in efficacy when compared to Treadmill training with basic physiotherapy for improving gait speed.	1	Druzbicki et al. 2015

1b	Cognitive-motor dual task training while treadmill walking with Conventional rehabilitation may produce greater improvements in gait speed than Single task training on Treadmill walking with Conventional rehabilitation.	1	Choi et al. 2015a
2	Treadmill training with Rhythmic auditory stimulation may produce greater improvements in gait speed than Overground training with Rhythmic auditory stimulation.	1	Park et al. 2015a
1b	Treadmill training with functional electrical stimulation on gluteus medius and tibialis anterior may produce greater improvements in gait speed than Treadmill training.	1	Cho et al. 2015c
1b	Treadmill training with Tilt sensor functional electrical stimulation with conventional physical therapy may produce greater improvements in gait speed than Treadmill training with Placebo Tilt sensor functional electrical stimulation with conventional physical therapy.	1	Hwang et al. 2015
2	Overground gait training with ankle mass may not have a difference in efficacy when compared to Overground gait training without mass or Treadmill gait training without mass for improving gait speed.	1	Bonnyaud et al. 2013b
1b	Body Weight-Supported Treadmill Training with functional electrical stimulation may produce greater improvements in gait speed than Body Weight Supported Treadmill Training.	1	Lee et al. 2013g
1b	Treadmill with optic flow with conventional physical therapy may produce greater improvements in gait speed than Treadmill with conventional physical therapy.	1	Kang et al. 2012
1b	There is conflicting evidence about the effect of Treadmill with optic flow with conventional physical therapy when compared to Conventional therapy for improving gait speed.	1	Kang et al. 2012
1b	Treadmill training with Virtual reality may produce greater improvements in gait speed than Treadmill training.	1	Yang et al. 2008
1b	Specialized task oriented locomotor training (includes using Tilt table, limb-load monitor, isokinetic device and treadmill training) with Conventional physiotherapy may not have a difference in efficacy when compared to Conventional physiotherapy for improving gait speed.	1	Richards et al. 2004
1b	Treadmill training and overground gait training may produce greater improvements in gait speed than Placebo program of low- intensity home exercise program with Telerehabilitation.	1	Ada et al. 2003
1b	Baseline conventional therapy with Treadmill training with partial body weight supported and Individual physical therapy may not have a difference in efficacy when compared to Baseline conventional therapy with Treadmill training with partial body weight supported for improving gait speed.	1	Werner et al. 2002a
1b	Early, intensive, gait- oriented Task specific training (isokinetic device, treadmill, tilt table) with conventional hospital care may not have a difference in efficacy when compared to Early, intensive traditional physical therapy approach with conventional hospital care or Conventional physical therapy and conventional hospital care or 60min/d, 5d/wk, 5wks for improving gait speed.	1	Richards et al. 1993

1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High-intensity speed-based treadmill training for improving gait endurance.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving gait endurance.	1	Madhavan et al. 2020
1b	Treadmill Training with Mirror Therapy may not have a difference in efficacy when compared to Treadmill Training with Sham for improving gait endurance.	1	Broderick et al. 2019
2	Hybrid Assistive Limb (HAL) exoskeleton with Bodyweight supported treadmill training may not have a difference in efficacy when compared to Conventional Physical therapy for improving gait endurance.	1	Sczesny-Kaiser et al. 2019
2	Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may produce greater improvements in gait endurance than Sham taping with treadmill training.	1	Kim & Kang 2018c
1b	Body weight support treadmill training with visual biofeedback may produce greater improvements in gait endurance than Body weight support treadmill training.	1	Druzbicki et al. 2018
1b	Aquatic-based treadmill aerobic training with conventional care may not have a difference in efficacy when compared to Land-based aerobic exercises on cycle ergometer with conventional care for improving gait endurance.	1	Han et al. 2018
1b	Rhythmic auditory stimulation with treadmill training and conventional physical therapy may produce greater improvements in gait endurance than Treadmill training with conventional physical therapy.	1	Mainka et al. 2018
1b	Rhythmic auditory stimulation with treadmill training and conventional physical therapy may not have a difference in efficacy when compared to Neurodevelopmental treatment with conventional physical therapy for improving gait endurance.	1	Mainka et al. 2018
1b	Whole body vibration with Treadmill training may not have a difference in efficacy when compared to Exercises on platform without vibration with Treadmill training for improving gait endurance.	1	Choi et al. 2017b
1b	There is conflicting evidence about the effect of High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc) when compared to Conventional physical therapy care for improving gait endurance.	1	Hornby et al. 2016

2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in gait endurance than Treadmill training.	1	Yoon & Kang 2016
2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in gait endurance than Inclined treadmill training.	1	Yoon & Kang 2016
2	Inclined treadmill training may produce greater improvements in gait endurance than Treadmill training.	1	Yoon & Kang 2016
1b	Virtual reality treadmill training-based community ambulation may not have a difference in efficacy when compared to Community ambulation training for improving gait endurance.	1	Kim et al. 2016c
1b	Virtual reality treadmill training-based community ambulation may not have a difference in efficacy when compared to Conventional rehabilitation for improving gait endurance.	1	Kim et al. 2016c
2	Task-oriented treadmill training with conventional therapy may produce greater improvements in gait endurance than Treadmill training with conventional therapy.	1	Kwon et al. 2015
1b	Treadmill training with visual biofeedback and basic physiotherapy may not have a difference in efficacy when compared to Treadmill training with basic physiotherapy for improving gait endurance.	1	Druzbicki et al. 2015
2	Treadmill training with Rhythmic auditory stimulation may produce greater improvements in gait endurance than Overground training with Rhythmic auditory stimulation.	1	Park et al. 2015a
1b	Treadmill training with functional electrical stimulation on gluteus medius and tibialis anterior may not have a difference in efficacy when compared to Treadmill training for improving gait endurance.	1	Cho et al. 2015c
1b	Treadmill with optic flow with conventional physical therapy may produce greater improvements in gait endurance than Treadmill with conventional physical therapy.	1	Kang et al. 2012
1b	There is conflicting evidence about the effect of Treadmill with optic flow with conventional physical therapy when compared to Conventional therapy for improving gait endurance.	1	Kang et al. 2012
1b	Aerobic training (treadmill and cycle ergometer) may not have a difference in efficacy when compared to Conventional rehabilitation for improving gait endurance.	1	Toledano-Zarhi et al. 2011
2	Treadmill training with Virtual reality may not have a difference in efficacy when compared to Stepping over real objects on 10m walkway for improving gait endurance.	1	Jaffe et al. 2004
1b	Treadmill training and overground gait training may produce greater improvements in gait endurance than Placebo program of low-intensity home exercise program with Telerehabilitation.	1	Ada et al. 2003

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Treadmill Training may not have a difference in efficacy when compared to Conventional Therapy for improving functional mobility.	6	Hu et al. 2023; Baer et al. 2018; Globas et al. 2012; Kuys et al. 2011; Macko et al. 2005; Laufer et al. 2001

1b	Treadmill Training with Incline may not have a difference in efficacy when compared to Treadmill Training with Decline or Level Treadmill Training for improving functional mobility.	2	Cheng et al. 2022; Carda et al. 2013
1b	Constraint Induced Movement with Home Exercise may not have a difference in efficacy when compared to Treadmill Training for improving functional mobility.	1	Silva et al. 2017
2	Treadmill Training with Foot Drop Stimulator may produce greater improvements in functional mobility than Foot Drop Stimulator.	1	Peishun et al. 2021
2	Treadmill Training with Proprioceptive Neuromuscular Facilitation may produce greater improvements in functional mobility than Treadmill Training.	1	Kim & Kang 2018c
1b	Treadmill Training with Obstacles may not have a difference in efficacy when compared to Treadmill Training for improving functional mobility.	1	Jeong et al. 2016
2	Treadmill Training on Unstable Surface may produce greater improvements in functional mobility than Treadmill Training.	1	Bang et al. 2014
2	Treadmill Training with Horizontal Force may produce greater improvements in functional mobility than Treadmill Training.	1	Na et al. 2015
2	Treadmill-based C-Mill (using gait-dependent augmented reality) may not have a difference in efficacy when compared to Overground walking therapy (walking-adaptability exercises with physical obstacles) for improving functional mobility.	1	Timmermans et al. 2021
1a	Treadmill Training with virtual reality may produce greater improvements in functional mobility than Other Training.	2	Cho et al. 2014; Cho et al. 2013c
2	Treadmill Training with Visual Deprivation may not have a difference in efficacy when compared to Treadmill Training for improving functional mobility.	1	Kim et al. 2014a
1a	Backward Treadmill Training may produce greater improvements in functional mobility than Treadmill or Conventional Rehabilitation.	3	Chang et al. 2021; Kim et al. 2017b; Takami et al. 2010

2	Backward treadmill with partial body weight supported may produce greater improvements in functional mobility than Forward treadmill with partial body weight supported treadmill.	1	Takami et al. 2010
2	Forward treadmill with partial BWS treadmill may produce greater improvements in functional mobility than Conventional rehabilitation.	1	Takami et al. 2010
1b	Treadmill Training with Overground Training may not have a difference in efficacy when compared to Home Exercise/ no treatment for improving functional mobility.	2	Ada et al. 2013; Moore et al. 2010
1b	Long-term Treadmill and Overground Walking may produce greater improvements in functional mobility than Short-term Treadmill and Overground Walking.	1	Ada et al. 2013
1b	High Intensity Treadmill Training may not have a difference in efficacy when compared to Low Intensity Treadmill Training for improving functional mobility.	1	Munari et al. 2018
1b	Speed Dependent Treadmill Training may produce greater improvements in functional mobility than Other Treadmill Training.	1	Pohl et al. 2002
2	Speed-dependent Treadmill Training may not have a difference in efficacy when compared to Task-oriented Training for improving functional mobility.	1	Sharma et al. 2014
2	Treadmill Training may not have a difference in efficacy when compared to Stretching for improving functional mobility.	1	Serra et al. 2022
1b	Treadmill Training with Orthotic Devices may produce greater improvements in functional mobility than Treadmill Training.	1	In et al. 2017
1b	Electromechanical gait trainer therapy with Conventional rehabilitation may produce greater improvements in functional mobility than Body weight-supported treadmill training with Conventional rehabilitation.	1	Werner et al. 2002b
1b	Treadmill Training with Action Observation may produce greater improvements in functional mobility than Treadmill Training.	1	Bang et al. 2013
2	Overground gait training + visual cue feedback may not have a difference in efficacy when compared to Standard physiotherapy for improving functional mobility.	1	Hollands et al. 2015
1b	Augmented reality treadmill-based gait adaptation training may produce greater improvements in functional mobility than Treadmill training with overground walking.	1	Yang et al. 2024a
1b	Rhythmic Auditory Stimulation with Custom Physiotherapy program and Treadmill gait training may produce greater improvements in functional mobility than Custom physiotherapy program with Treadmill gait training.	1	Ahmed et al. 2023
2	Treadmill training with HEALBOT exoskeleton may produce greater improvements in functional mobility than Treadmill training.	1	Yoo et al. 2023a
2	Functional electrical stimulation with treadmill training may produce greater improvements in functional mobility than Treadmill training.	1	Dantas et al. 2023
1b	Bilateral transcranial direct current stimulation and Treadmill may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Treadmill for improving functional mobility.	1	Wong et al. 2023
1b	Bilateral transcranial direct current stimulation and Treadmill may not have a difference in efficacy when compared to Cathodal transcranial direct current stimulation and Treadmill for improving functional mobility.	1	Wong et al. 2023

1b	Functional electrical stimulation with treadmill gait training may produce greater improvements in functional mobility than Sham Functional electrical stimulation with treadmill gait training.	1	Lee et al. 2022d
1b	Bicephalic Transcranial direct-current stimulation with Footdrop stimulator and Treadmill gait training may not have a difference in efficacy when compared to Sham transcranial direct-current stimulation with Footdrop stimulator and treadmill gait training for improving functional mobility.	1	da Cunha et al. 2022
1b	Body weight supported treadmill training (BWST) with conventional rehabilitation may produce greater improvements in functional mobility than Overground gait training with conventional rehabilitation.	1	Gangopadhyay et al. 2021
1b	Dual-task gait training with treadmill may not have a difference in efficacy when compared to Single-task gait training with treadmill for improving functional mobility.	1	Baek et al. 2021
2	Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not have a difference in efficacy when compared to Sham Combined aerobic and resistance training with Sham Cognitive training for improving functional mobility.	1	Koch et al. 2020
2	Treadmill training using insole on less affected side may produce greater improvements in functional mobility than Treadmill training.	1	An et al. 2020
1b	Gait training with Gait Exercise Assist Robot (GEAR) may produce greater improvements in functional mobility than Gait training with treadmill.	1	Ogino et al. 2020
1b	High frequency repetitive transcranial magnetic stimulation with Treadmill Training may produce greater improvements in functional mobility than Sham repetitive transcranial magnetic stimulation with Treadmill Training.	1	Lee et al. 2020a
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving functional mobility.	1	Madhavan et al. 2020
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High- intensity speed-based treadmill training for improving functional mobility.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High-intensity speed-based treadmill training for improving functional mobility.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving functional mobility.	1	Madhavan et al. 2020

1b	Dual-task (virtual reality-based UL training while walking on treadmill) may not have a difference in efficacy when compared to Single task treadmill walking for improving functional mobility.	1	Fishbein et al. 2019
2	Hybrid Assistive Limb (HAL) exoskeleton with Bodyweight supported treadmill training may not have a difference in efficacy when compared to Conventional Physical therapy for improving functional mobility.	1	Sczesny-Kaiser et al. 2019
2	Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may produce greater improvements in functional mobility than Sham taping with treadmill training.	1	Kim & Kang 2018c
1b	Body weight support treadmill training with visual biofeedback may not have a difference in efficacy when compared to Body weight support treadmill training for improving functional mobility.	1	Druzbicki et al. 2018
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may not have a difference in efficacy when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy for improving functional mobility.	1	Park et al. 2018a
1b	There is conflicting evidence about the effect of Body weight supported treadmill training with anodal transcranial direct current stimulation when compared to Body weight supported treadmill training with sham transcranial direct current stimulation for improving functional mobility.	1	Manji et al. 2018
1b	High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc) may not have a difference in efficacy when compared to Conventional physical therapy care for improving functional mobility.	1	Hornby et al. 2016
1b	Treadmill training with Gait Trainer 2 Biodex biofeedback (30-45min/d) with Conventional individual exercises may not have a difference in efficacy when compared to Treadmill training without biofeedback with Conventional individual exercises for improving functional mobility.	1	Druzbicki et al. 2016b
1b	Aquatic therapy (physical therapy exercises) with aquatic treadmill may produce greater improvements in functional mobility than Conventional physical therapy exercise with land-based treadmill.	1	Zhang et al. 2016
2	Treadmill training with Rhythmic auditory stimulation may produce greater improvements in functional mobility than Treadmill training.	1	Song & Ryu 2016
1b	Treadmill training with Rhythmic auditory feedback may produce greater improvements in functional mobility than Treadmill training.	1	Yang et al. 2016
2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in functional mobility than Treadmill training.	1	Yoon & Kang 2016
2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in functional mobility than Inclined treadmill training.	1	Yoon & Kang 2016
2	Inclined treadmill training may produce greater improvements in functional mobility than Treadmill training.	1	Yoon & Kang 2016
1b	Virtual reality treadmill training-based community ambulation may not have a difference in efficacy when compared to Community ambulation training for improving functional mobility.	1	Kim et al. 2016c
1b	Virtual reality treadmill training-based community ambulation may produce greater improvements in functional mobility than Conventional rehabilitation.	1	Kim et al. 2016c

2	Task-oriented treadmill training with conventional therapy may produce greater improvements in functional mobility than Treadmill training with conventional therapy.	1	Kwon et al. 2015
1b	Treadmill training with visual biofeedback and basic physiotherapy may not have a difference in efficacy when compared to Treadmill training with basic physiotherapy for improving functional mobility.	1	Druzbicki et al. 2015
1b	Cognitive-motor dual task training while treadmill walking with Conventional rehabilitation may not have a difference in efficacy when compared to Single task training on Treadmill walking with Conventional rehabilitation for improving functional mobility.	1	Choi et al. 2015a
2	Treadmill training with Rhythmic auditory stimulation may produce greater improvements in functional mobility than Overground training with Rhythmic auditory stimulation.	1	Park et al. 2015a
1b	Treadmill training with Tilt sensor functional electrical stimulation with conventional physical therapy may produce greater improvements in functional mobility than Treadmill training with Placebo Tilt sensor functional electrical stimulation with conventional physical therapy.	1	Hwang et al. 2015
1b	Body Weight-Supported Treadmill Training with functional electrical stimulation may produce greater improvements in functional mobility than Body Weight Supported Treadmill Training.	1	Lee et al. 2013g
2	Underwater treadmill walking may not have a difference in efficacy when compared to Overground treadmill walking for improving functional mobility.	1	Park et al. 2012
1b	There is conflicting evidence about the effect of Treadmill training with Virtual reality when compared to Treadmill training for improving functional mobility.	2	Jung et al. 2012; Yang et al. 2008
1b	Treadmill with optic flow with conventional physical therapy may produce greater improvements in functional mobility than Treadmill with conventional physical therapy.	1	Kang et al. 2012
1b	There is conflicting evidence about the effect of Treadmill with optic flow with conventional physical therapy when compared to Conventional therapy for improving functional mobility.	1	Kang et al. 2012
1b	Aerobic training (treadmill and cycle ergometer) may not have a difference in efficacy when compared to Conventional rehabilitation for improving functional mobility.	1	Toledano-Zarhi et al. 2011
2	Treadmill training with Virtual reality and Conventional rehabilitation may not have a difference in efficacy when compared to Treadmill training with Conventional rehabilitation for improving functional mobility.	1	Yang et al. 2011
1b	Specialized task oriented locomotor training (includes using Tilt table, limb-load monitor, isokinetic device and treadmill training) with Conventional physiotherapy may not have a difference in efficacy when compared to Conventional physiotherapy for improving functional mobility.	1	Richards et al. 2004
2	Treadmill training with Virtual reality may not have a difference in efficacy when compared to Stepping over real objects on 10m walkway for improving functional mobility.	1	Jaffe et al. 2004
1b	Baseline conventional therapy with Treadmill training with partial body weight supported and Individual physical therapy may produce greater improvements in functional mobility than Baseline conventional therapy with Treadmill training with partial body weight supported.	1	Werner et al. 2002a

1b	Treadmill training with BWS via overhead harness may not have a difference in efficacy when compared to Overground gait training for improving functional mobility.	1	Ada et al. 2010

BALANCE

1b	Treadmill training with Tilt sensor functional electrical stimulation with conventional physical therapy may produce greater improvements in balance than Treadmill training with Placebo Tilt sensor functional electrical stimulation with conventional physical therapy.	1	Hwang et al. 2015
1b	Body Weight-Supported Treadmill Training with functional electrical stimulation may produce greater improvements in balance than Body Weight Supported Treadmill Training.	1	Lee et al. 2013g
1b	Treadmill with optic flow with conventional physical therapy may not have a difference in efficacy when compared to Treadmill with conventional physical therapy for improving balance.	1	Kang et al. 2012
1b	Treadmill with optic flow with conventional physical therapy may produce greater improvements in balance than Conventional therapy.	1	Kang et al. 2012
1b	Aerobic training (treadmill and cycle ergometer) may not have a difference in efficacy when compared to Conventional rehabilitation for improving balance.	1	Toledano-Zarhi et al. 2011
1b	Specialized task oriented locomotor training (includes using Tilt table, limb-load monitor, isokinetic device and treadmill training) with Conventional physiotherapy may not have a difference in efficacy when compared to Conventional physiotherapy for improving balance.	1	Richards et al. 2004
1b	Early, intensive, gait- oriented Task specific training (isokinetic device, treadmill, tilt table) with conventional hospital care may not have a difference in efficacy when compared to Early, intensive traditional physical therapy approach with conventional hospital care or Conventional physical therapy and conventional hospital care or 60min/d, 5d/wk, 5wks for improving balance.	1	Richards et al. 1993

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Treadmill Training may not have a difference in efficacy when compared to Conventional Therapy for improving falls and fear of falling.	1	Hu et al. 2023
1b	Body weight supported Treadmill Training may produce greater improvements in falls and fear of falling than Conventional Therapy.	1	Mustafaoglu et al. 2018
1b	Body weight supported treadmill training may result in lesser improvements in falls and fear of falling when compared to body weight supported treadmill training with Conventional care.	1	Mustafaoglu et al. 2018
1b	BWS treadmill training with Conventional care may produce greater improvements in falls and fear of falling than Conventional training.	1	Mustafaoglu et al. 2018
1a	Body weight supported Treadmill Training may not have a difference in efficacy when compared to Overground Walking for improving falls and fear of falling.	3	DePaul et al. 2015; Middleton et al. 2014; Dean et al. 2010
2	Body weight supported Treadmill Training with Mobility Skills may not have a difference in efficacy when compared to body weight supported Treadmill Training for improving falls and fear of falling.	1	Graham et al. 2018
1b	Body weight supported Treadmill Training for Different Durations may not have a difference in efficacy when compared to Home Exercise for improving falls and fear of falling.	1	Duncan et al. 2011

2	Treadmill Training with Load may not have a difference in efficacy when compared to Treadmill Training without Load or Conventional Therapy for improving falls and fear of falling.	1	de Lima Gomes et al. 2017
1b	Perturbation Treadmill Training may not have a difference in efficacy when compared to Treadmill Training for improving falls and fear of falling.	1	Esmaeili et al. 2020
1b	Treadmill Training with Obstacles may not have a difference in efficacy when compared to Treadmill Training for improving falls and fear of falling.	1	Jeong et al. 2016
1b	Backward Treadmill Training may not have a difference in efficacy when compared to Treadmill or Conventional Rehabilitation for improving falls and fear of falling.	1	Bansal et al. 2023
1b	Treadmill Training with Overground Training may not have a difference in efficacy when compared to Home Exercise/ no treatment for improving falls and fear of falling.	1	Ada et al. 2013
2	Overground gait training + visual cue feedback may not have a difference in efficacy when compared to Standard physiotherapy for improving falls and fear of falling.	1	Hollands et al. 2015
1b	Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not have a difference in efficacy when compared to Sham taping with exercise training for improving falls and fear of falling.	1	Wang et al. 2022c
1b	Dual-task gait training with treadmill may not have a difference in efficacy when compared to Single-task gait training with treadmill for improving falls and fear of falling.	1	Baek et al. 2021
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving falls and fear of falling.	1	Madhavan et al. 2020
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High- intensity speed-based treadmill training for improving falls and fear of falling.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High-intensity speed-based treadmill training for improving falls and fear of falling.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving falls and fear of falling.	1	Madhavan et al. 2020
1b	Dual-task (virtual reality-based UL training while walking on treadmill) may produce greater improvements in falls and fear of falling than Single task treadmill walking.	1	Fishbein et al. 2019

2	Gait training program (treadmill + overground walking) wearing a hip-assist robot may produce greater improvements in falls and fear of falling than Gait training (treadmill training + over ground walking).	1	Lee et al. 2019a
1b	High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc) may not have a difference in efficacy when compared to Conventional physical therapy care for improving falls and fear of falling.	1	Hornby et al. 2016
1b	Virtual reality treadmill training-based community ambulation may not have a difference in efficacy when compared to Community ambulation training for improving falls and fear of falling.	1	Kim et al. 2016c
1b	Virtual reality treadmill training-based community ambulation may produce greater improvements in falls and fear of falling than Conventional rehabilitation.	1	Kim et al. 2016c
1b	There is conflicting evidence about the effect of Treadmill training with Virtual reality when compared to Treadmill training for improving falls and fear of falling.	2	Jung et al. 2012; Yang et al. 2008

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**

1b	Bicephalic Transcranial direct-current stimulation with Footdrop stimulator and Treadmill gait training may not have a difference in efficacy when compared to Sham transcranial direct-current stimulation with Footdrop stimulator and treadmill gait training for improving quality of life.	1	da Cunha et al. 2022

2	Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not have a difference in efficacy when compared to Sham Combined aerobic and resistance training with Sham Cognitive training for improving quality of life.	1	Koch et al. 2020
1b	Gait training with Gait Exercise Assist Robot (GEAR) may not have a difference in efficacy when compared to Gait training with treadmill for improving quality of life.	1	Ogino et al. 2020
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving quality of life.	1	Madhavan et al. 2020
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may produce greater improvements in quality of life than 15min rest with High- intensity speed-based treadmill training.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High-intensity speed-based treadmill training for improving quality of life.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving quality of life.	1	Madhavan et al. 2020
1b	Water-based aerobic exercise on a motorized aquatic treadmill with Conventional rehabilitation therapy may not have a difference in efficacy when compared to Aerobic Exercise (by upper and lower body ergometers) with Conventional rehabilitation therapy for improving quality of life.	1	Lee et al. 2018d
1b	High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc) may produce greater improvements in quality of life than Conventional physical therapy care.	1	Hornby et al. 2016
1b	Treadmill training and overground gait training may not have a difference in efficacy when compared to Placebo program of low-intensity home exercise program with Telerehabilitation for improving quality of life.	1	Ada et al. 2003

Other Associated Outcome Measures

MOOD			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Treadmill Training with Increased Speed may not have a difference in efficacy when compared to Treadmill Training with Increased Incline for improving mood.	1	Alipsatici et al. 2020

FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Body weight supported Treadmill Training may not have a difference in efficacy when compared to Conventional Therapy for improving fatigue and sleep.	1	Nave et al. 2019
2	Treadmill Training may not have a difference in efficacy when compared to Stretching for improving fatigue and sleep.	1	Serra et al. 2022

COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Body weight supported Treadmill Training may not have a difference in efficacy when compared to Conventional Therapy for improving cognition.	1	Nave et al. 2019
2	Treadmill Training with Load may not have a difference in efficacy when compared to Treadmill Training without Load or Conventional Therapy for improving cognition.	1	Kim & Yim 2017c
2	Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not have a difference in efficacy when compared to Sham Combined aerobic and resistance training with Sham Cognitive training for improving cognition.	1	Koch et al. 2020

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Body weight supported Treadmill Training may not have a difference in efficacy when compared to Conventional Therapy for improving upper extremity function.	1	Nave et al. 2019
2	Treadmill Training with Load may not have a difference in efficacy when compared to Treadmill Training without Load or Conventional Therapy for improving upper extremity function.	1	Kim & Yim 2017c
1b	Treadmill Training with Orthotic Devices may produce greater improvements in upper extremity function than Treadmill Training.	1	Park et al. 2024b
2	Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not have a difference in efficacy when compared to Sham Combined aerobic and resistance training with Sham Cognitive training for improving upper extremity function.	1	Koch et al. 2020
2	Gait training program (treadmill + overground walking) wearing a hip-assist robot may produce greater improvements in upper extremity function than Gait training (treadmill training + over ground walking).	1	Lee et al. 2019a
1b	Specialized task oriented locomotor training (includes using Tilt table, limb-load monitor, isokinetic device and treadmill training) with Conventional physiotherapy may not have a difference in efficacy when compared to Conventional physiotherapy for improving upper extremity function.	1	Richards et al. 2004

Key Points

- Treadmill Training may be beneficial for improving aerobic measures and gait endurance, but not biomechanical gait measures, activities of daily living, gait speed, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy.

- Treadmill Training may not be beneficial for improving biomechanical gait measures, range of motion, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Overground Training.
- Treadmill training with Rehabilitation program may be beneficial for improving gait speed and gait endurance after stroke when compared to Overground gait training with Rehabilitation program; the literature is mixed regarding biomechanical gait measures.
- Body weight supported Treadmill Training may be beneficial for improving motor recovery, gait speed, and falls and fear of falling, but not biomechanical gait measures, muscle strength, aerobic measures, activities of daily living, functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy; the literature is mixed regarding neurophysiological measures and gait endurance.
- Body weight supported treadmill training may not be beneficial for improving gait speed after stroke when compared to body weight supported treadmill training with Conventional care; Body weight supported treadmill training may result in lesser improvements in functional mobility, balance, and falls and fear of falling when compared to body weight supported treadmill training with Conventional care.
- Body weight supported Treadmill Training may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, aerobic measures, sensory and proprioceptive function, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Overground Walking.
- Body weight supported Treadmill Training may be beneficial for improving biomechanical gait measures, neurophysiological measures, and functional mobility, but not motor recovery and gait endurance, after stroke when compared to Treadmill Training; the literature is mixed regarding gait speed and balance.
- Body weight supported Treadmill Training with Mobility Skills may not be beneficial for improving gait speed, gait endurance, balance, and falls and fear of falling after stroke when compared to body weight supported Treadmill Training.
- Body weight supported treadmill with upper extremity ergometry training may be beneficial for improving gait speed, but not muscle strength and gait endurance, after stroke when compared to Resistive leg cycling with upper extremity ergometry training.
- Body weight supported treadmill with upper extremity ergometry training may not be beneficial for improving muscle strength, gait speed, and gait endurance after stroke when compared to body weight supported treadmill with resistive leg cycling training or body weight supported treadmill with lower extremity progressive resistive exercise.
- Body weight supported Treadmill Training with Facilitation Technique may not be beneficial for improving motor recovery, biomechanical gait measures, activities of daily living, and gait speed after stroke when compared to body weight supported Training with Mechanical Assistance.
- Body weight supported Treadmill Training for Different Durations may not be beneficial for improving motor recovery, gait speed, gait endurance, balance, falls and fear of falling, and quality of life after stroke when compared to Home Exercise.
- Treadmill Training with Nordic Poles may be beneficial for improving activities of daily living, gait endurance, functional mobility, and balance, but not gait speed, after stroke when compared to Treadmill Training.
- Treadmill Training with Load may not be beneficial for improving motor recovery, biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, activities of daily living, gait speed, and falls and fear of falling after stroke when compared to Treadmill Training without Load or Conventional Therapy; the literature is mixed regarding functional mobility.
- Treadmill Training with Incline may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, spasticity, activities of daily living, functional mobility, and balance after stroke when compared to Treadmill Training with Decline or Level Treadmill Training; Treadmill Training with Incline may result in lesser improvements in gait endurance when compared to Treadmill Training with Decline or Level Treadmill Training; the literature is mixed regarding range of motion and gait speed.
- Treadmill Training with Increased Speed may be beneficial for improving biomechanical gait measures, gait speed, and gait endurance, but not balance, after stroke when compared to Treadmill Training with Increased Incline.
- Constraint Induced Movement with Home Exercise may not be beneficial for improving biomechanical gait measures, functional mobility, and balance after stroke when compared to Treadmill Training.

- Treadmill Training with Foot Drop Stimulator may be beneficial for improving biomechanical gait measures, spasticity, range of motion, neurophysiological measures, and functional mobility after stroke when compared to Foot Drop Stimulator.
- Perturbation Treadmill Training may be beneficial for improving balance, but not muscle strength, activities of daily living, gait speed, and falls and fear of falling, after stroke when compared to Treadmill Training.
- Turning Treadmill Training may be beneficial for improving muscle strength, gait speed, and balance, but not biomechanical gait measures and biomechanical balance measures, after stroke when compared to Treadmill Training.
- Treadmill Training with Mirror Therapy may not be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Treadmill Training.
- Treadmill Training with Proprioceptive Neuromuscular Facilitation may be beneficial for improving gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill Training.
- Body weight supported Treadmill Training may not be beneficial for improving biomechanical gait measures, range of motion, activities of daily living, and gait speed after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Treadmill Training with Obstacles may be beneficial for improving gait endurance and balance, but not gait speed, functional mobility, and falls and fear of falling, after stroke when compared to Treadmill Training.
- Treadmill Training on Unstable Surface may be beneficial for improving gait endurance and functional mobility, but not gait speed, after stroke when compared to Treadmill Training.
- Treadmill Training with Handrails may be beneficial for improving biomechanical gait measures after stroke when compared to Treadmill Training.
- Treadmill Training with Horizontal Force may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Treadmill Training; the literature is mixed regarding balance.
- Treadmill-based C-Mill (using gait-dependent augmented reality) may not be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Overground walking therapy (walking-adaptability exercises with physical obstacles).
- Treadmill Training with virtual reality may be beneficial for improving biomechanical gait measures, gait speed, functional mobility, and balance, but not biomechanical balance measures, after stroke when compared to Other Training.
- Treadmill Training with Smartphone Application may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Treadmill Training.
- Treadmill Training with Visual Deprivation may be beneficial for improving gait speed, but not gait endurance and functional mobility, after stroke when compared to Treadmill Training; the literature is mixed regarding biomechanical gait measures.
- Backward Treadmill Training may be beneficial for improving biomechanical balance measures and functional mobility, but not motor recovery, biomechanical gait measures, spasticity, gait speed, balance, and falls and fear of falling, after stroke when compared to Treadmill or Conventional Rehabilitation; the literature is mixed regarding aerobic measures and gait endurance.
- Body weight supported, backward and forward treadmill training may not be beneficial for improving biomechanical gait measures after stroke when compared to body weight supported, forward treadmill training or body weight supported, backward treadmill training.
- Backward treadmill with partial body weight supported may be beneficial for improving functional mobility, but not biomechanical gait measures, gait speed, and balance, after stroke when compared to Forward treadmill with partial body weight supported treadmill.
- Treadmill Training with Overground Training may be beneficial for improving gait speed and gait endurance, but not biomechanical gait measures, aerobic measures, activities of daily living, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Home Exercise/ no treatment.

- Long-term Treadmill and Overground Walking may be beneficial for improving gait endurance, functional mobility, and quality of life, but not biomechanical gait measures, activities of daily living, and gait speed, after stroke when compared to Short-term Treadmill and Overground Walking.
- High Intensity Treadmill Training may be beneficial for improving biomechanical gait measures, but not aerobic measures, gait speed, gait endurance, functional mobility, and quality of life, after stroke when compared to Low Intensity Treadmill Training.
- Fast Speed Treadmill Training with functional electrical stimulation may be beneficial for improving gait speed, but not gait endurance, after stroke when compared to Self-selected or Fast Speed Treadmill Training.
- Speed Dependent Treadmill Training may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility, but not balance, after stroke when compared to Other Treadmill Training.
- Body weight supported treadmill training (fast speed) may result in lesser improvements in gait speed when compared to body weight supported treadmill training (slow speed) or body weight supported treadmill training (variable speed).
- Speed-dependent Treadmill Training may not be beneficial for improving functional mobility and balance after stroke when compared to Task-oriented Training.
- Error Augmentation Treadmill Training may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Treadmill Training.
- Treadmill Training may be beneficial for improving aerobic measures and balance, but not neurophysiological measures, gait speed, and functional mobility, after stroke when compared to Stretching; the literature is mixed regarding gait endurance.
- Treadmill Training with Orthotic Devices may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Treadmill Training; the literature is mixed regarding balance.
- Electromechanical gait trainer therapy with Conventional rehabilitation may be beneficial for improving functional mobility, but not motor recovery, spasticity, and gait speed, after stroke when compared to Body weight-supported treadmill training with Conventional rehabilitation.
- Treadmill Training with Action Observation may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill Training.
- Circular treadmill training with ambulation training may be beneficial for improving biomechanical gait measures, neurophysiological measures, and gait speed after stroke when compared to Regular treadmill training+ ambulation training.
- Overground gait training + visual cue feedback may not be beneficial for improving motor recovery, biomechanical gait measures, gait speed, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Standard physiotherapy.
- Treadmill walking training + conventional PT may not be beneficial for improving gait speed and gait endurance after stroke when compared to conventional PT.
- Augmented reality treadmill-based gait adaptation training may be beneficial for improving functional mobility and balance after stroke when compared to Treadmill training with overground walking; the literature is mixed regarding gait speed.
- Rhythmic Auditory Stimulation with Custom Physiotherapy program and Treadmill gait training may be beneficial for improving gait speed and functional mobility after stroke when compared to Custom physiotherapy program with Treadmill gait training; the literature is mixed regarding biomechanical gait measures.
- Treadmill training with HEALBOT exoskeleton may be beneficial for improving neurophysiological measures and functional mobility, but not balance, after stroke when compared to Treadmill training; the literature is mixed regarding biomechanical gait measures and gait speed.
- Functional electrical stimulation with treadmill training may be beneficial for improving gait endurance and functional mobility, but not gait speed, after stroke when compared to Treadmill training.
- Anodal transcranial direct current stimulation with Treadmill training may not be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to Sham transcranial direct current stimulation with Treadmill training.

- Bilateral transcranial direct current stimulation and Treadmill may not be beneficial for improving motor recovery, biomechanical gait measures, neurophysiological measures, gait speed, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with Treadmill.
- Bilateral transcranial direct current stimulation and Treadmill may be beneficial for improving motor recovery, biomechanical gait measures, neurophysiological measures, and gait speed, but not functional mobility, after stroke when compared to Cathodal transcranial direct current stimulation and Treadmill.
- Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, balance, and falls and fear of falling after stroke when compared to Sham taping with exercise training.
- Underwater Treadmill gait training with conventional rehabilitation may not be beneficial for improving biomechanical gait measures after stroke when compared to Overground gait training with conventional rehabilitation; the literature is mixed regarding gait speed.
- Functional electrical stimulation with treadmill gait training may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Sham Functional electrical stimulation with treadmill gait training.
- Bicephalic Transcranial direct-current stimulation with Footdrop stimulator and Treadmill gait training may not be beneficial for improving spasticity, gait endurance, functional mobility, and quality of life after stroke when compared to Sham transcranial direct-current stimulation with Footdrop stimulator and treadmill gait training.
- Body weight supported treadmill training (BWST) with conventional rehabilitation may be beneficial for improving biomechanical gait measures, gait speed, functional mobility, and balance after stroke when compared to Overground gait training with conventional rehabilitation.
- Dual-task gait training with treadmill may be beneficial for improving gait speed, but not biomechanical gait measures, functional mobility, and falls and fear of falling, after stroke when compared to Single-task gait training with treadmill.
- Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not be beneficial for improving gait speed, gait endurance, functional mobility, and quality of life after stroke when compared to Sham Combined aerobic and resistance training with Sham Cognitive training.
- Treadmill training using insole on less affected side may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill training.
- Gait training with Gait Exercise Assist Robot (GEAR) may be beneficial for improving functional mobility, but not biomechanical gait measures, gait speed, and quality of life, after stroke when compared to Gait training with treadmill; the literature is mixed regarding gait endurance.
- High frequency repetitive transcranial magnetic stimulation with Treadmill Training may be beneficial for improving gait speed, gait endurance, and functional mobility after stroke when compared to Sham repetitive transcranial magnetic stimulation with Treadmill Training.
- Cerebellar transcranial direct current stimulation with split-belt treadmill training may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Sham cerebellar transcranial direct current stimulation with split-belt treadmill training.
- Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training).
- Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may be beneficial for improving quality of life, but not motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, after stroke when compared to 15min rest with High- intensity speed-based treadmill training.

- Backward treadmill training with botulinum toxin type A therapy may be beneficial for improving biomechanical balance measures and gait speed, but not biomechanical gait measures and spasticity, after stroke when compared to forward treadmill training with botulinum toxin type A therapy.
- High-Intensity Interval Training – Treadmill may be beneficial for improving neurophysiological measures after stroke when compared to Moderate-intensity Continuous Exercise - Treadmill; the literature is mixed regarding gait speed.
- Dual-task (virtual reality-based UL training while walking on treadmill) may be beneficial for improving gait speed, balance, and falls and fear of falling, but not functional mobility, after stroke when compared to Single task treadmill walking.
- Treadmill Training with Mirror Therapy may not be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Treadmill Training with Sham.
- Gait training program (treadmill + overground walking) wearing a hip-assist robot may be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, gait speed, and falls and fear of falling, but not balance, after stroke when compared to Gait training (treadmill training + over ground walking).
- Hybrid Assistive Limb (HAL) exoskeleton with Bodyweight supported treadmill training may not be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Conventional Physical therapy.
- High Frequency repetitive transcranial magnetic stimulation (5Hz) with Treadmill Training may be beneficial for improving motor recovery and gait speed, but not neurophysiological measures, after stroke when compared to Sham repetitive transcranial magnetic stimulation with Treadmill Training.
- Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may be beneficial for improving gait endurance and functional mobility after stroke when compared to Sham taping with treadmill training.
- Body weight support treadmill training with visual biofeedback may be beneficial for improving gait endurance, but not biomechanical gait measures and functional mobility, after stroke when compared to Body weight support treadmill training; the literature is mixed regarding gait speed.
- Water-based aerobic exercise on a motorized aquatic treadmill with Conventional rehabilitation therapy may not be beneficial for improving motor recovery, aerobic measures, activities of daily living, balance, and quality of life after stroke when compared to Aerobic Exercise (by upper and lower body ergometers) with Conventional rehabilitation therapy; the literature is mixed regarding muscle strength.
- Aquatic-based treadmill aerobic training with conventional care may be beneficial for improving aerobic measures, but not activities of daily living and gait endurance, after stroke when compared to Land-based aerobic exercises on cycle ergometer with conventional care.
- Rhythmic auditory stimulation with treadmill training and conventional physical therapy may be beneficial for improving gait endurance, but not biomechanical gait measures and biomechanical balance measures, after stroke when compared to Treadmill training with conventional physical therapy; the literature is mixed regarding gait speed.
- Rhythmic auditory stimulation with treadmill training and conventional physical therapy may not be beneficial for improving biomechanical balance measures and gait endurance after stroke when compared to Neurodevelopmental treatment with conventional physical therapy; the literature is mixed regarding biomechanical gait measures and gait speed.
- Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may be beneficial for improving motor recovery and muscle strength, but not activities of daily living, gait speed, functional mobility, and balance, after stroke when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.
- Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may be beneficial for improving motor recovery, gait speed, and muscle strength, but not activities of daily living, after stroke when compared to Conventional physical therapy with treadmill training.
- Body weight supported treadmill training with anodal transcranial direct current stimulation may be beneficial for improving gait speed, but not motor recovery and balance, after stroke when compared to Body weight supported treadmill training with sham transcranial direct current stimulation; the literature is mixed regarding functional mobility.

- Whole body vibration with Treadmill training may be beneficial for improving biomechanical gait measures and gait speed, but not gait endurance, after stroke when compared to Exercises on platform without vibration with Treadmill training.
- High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc) may be beneficial for improving gait speed and quality of life, but not functional mobility, balance, and falls and fear of falling, after stroke when compared to Conventional physical therapy care; the literature is mixed regarding biomechanical gait measures and gait endurance.
- Treadmill training with visual biofeedback and physiotherapy exercises may not be beneficial for improving biomechanical gait measures and range of motion after stroke when compared to Treadmill training with physiotherapy exercises.
- Treadmill training with Gait Trainer 2 Biodex biofeedback (30-45min/d) with Conventional individual exercises may not be beneficial for improving biomechanical balance measures, functional mobility, and balance after stroke when compared to Treadmill training without biofeedback with Conventional individual exercises.
- Aquatic therapy (physical therapy exercises) with aquatic treadmill may be beneficial for improving activities of daily living and functional mobility, but not spasticity and neurophysiological measures, after stroke when compared to Conventional physical therapy exercise with land-based treadmill; the literature is mixed regarding muscle strength and range of motion.
- Treadmill training with Rhythmic auditory stimulation may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Treadmill training.
- Treadmill training with Rhythmic auditory feedback may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Treadmill training.
- Inclined treadmill training with Rhythmic auditory stimulation may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Treadmill training.
- Virtual reality treadmill training-based community ambulation may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and falls and fear of falling after stroke when compared to Community ambulation training.
- Virtual reality treadmill training-based community ambulation may be beneficial for improving functional mobility and falls and fear of falling, but not biomechanical gait measures, gait speed, and gait endurance, after stroke when compared to Conventional rehabilitation.
- Treadmill training with Virtual reality and Ankle robotics may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, range of motion, and gait speed after stroke when compared to Seated training with Virtual reality and Ankle robotics.
- Task-oriented treadmill training with conventional therapy may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill training with conventional therapy.
- Partial body-weight support treadmill training with Visual biofeedback may not be beneficial for improving biomechanical gait measures and range of motion after stroke when compared to Partial body-weight support treadmill training.
- Treadmill training with visual biofeedback and basic physiotherapy may not be beneficial for improving biomechanical gait measures, activities of daily living, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill training with basic physiotherapy.
- Cognitive-motor dual task training while treadmill walking with Conventional rehabilitation may be beneficial for improving gait speed, but not functional mobility, after stroke when compared to Single task training on Treadmill walking with Conventional rehabilitation.
- Treadmill training with Rhythmic auditory stimulation may be beneficial for improving gait speed, gait endurance, and functional mobility after stroke when compared to Overground training with Rhythmic auditory stimulation; the literature is mixed regarding biomechanical gait measures.
- Treadmill training with Virtual reality may be beneficial for improving biomechanical balance measures after stroke when compared to Conventional rehabilitation.

- Treadmill training with functional electrical stimulation on gluteus medius and tibialis anterior may be beneficial for improving gait speed, but not gait endurance and balance, after stroke when compared to Treadmill training; the literature is mixed regarding biomechanical gait measures and muscle strength.
- Treadmill training with Tilt sensor functional electrical stimulation with conventional physical therapy may be beneficial for improving gait speed, functional mobility, and balance, but not muscle strength, after stroke when compared to Treadmill training with Placebo Tilt sensor functional electrical stimulation with conventional physical therapy.
- Overground gait training with ankle mass may not be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to Overground gait training without mass or Treadmill gait training without mass.
- Body Weight-Supported Treadmill Training with functional electrical stimulation may be beneficial for improving biomechanical gait measures, gait speed, functional mobility, and balance after stroke when compared to Body Weight Supported Treadmill Training.
- Underwater treadmill walking may be beneficial for improving biomechanical gait measures and neurophysiological measures, but not functional mobility, after stroke when compared to Overground treadmill walking.
- Treadmill training with Virtual reality may be beneficial for improving gait speed after stroke when compared to Treadmill training; the literature is mixed regarding functional mobility and falls and fear of falling.
- Treadmill with optic flow with conventional physical therapy may be beneficial for improving gait speed, gait endurance, and functional mobility, but not balance, after stroke when compared to Treadmill with conventional physical therapy.
- Treadmill with optic flow with conventional physical therapy may be beneficial for improving balance after stroke when compared to Conventional therapy; the literature is mixed regarding gait speed, gait endurance, and functional mobility.
- Aerobic training (treadmill and cycle ergometer) may not be beneficial for improving aerobic measures, gait endurance, functional mobility, and balance after stroke when compared to Conventional rehabilitation.
- Treadmill training with Virtual reality and Conventional rehabilitation may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, and functional mobility after stroke when compared to Treadmill training with Conventional rehabilitation.
- Aerobic training (cycle ergometer, treadmill, balance) may be beneficial for improving aerobic measures and activities of daily living after stroke when compared to Conventional rehabilitation.
- Specialized task oriented locomotor training (includes using Tilt table, limb-load monitor, isokinetic device and treadmill training) with Conventional physiotherapy may not be beneficial for improving motor recovery, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Conventional physiotherapy.
- Treadmill training with Virtual reality may not be beneficial for improving motor recovery, biomechanical gait measures, gait endurance, and functional mobility after stroke when compared to Stepping over real objects on 10m walkway.
- Treadmill training and overground gait training may be beneficial for improving gait speed and gait endurance, but not quality of life, after stroke when compared to Placebo program of low- intensity home exercise program with Telerehabilitation; the literature is mixed regarding biomechanical gait measures.
- Baseline conventional therapy with Treadmill training with partial body weight supported and Individual physical therapy may be beneficial for improving functional mobility, but not motor recovery and gait speed, after stroke when compared to Baseline conventional therapy with Treadmill training with partial body weight supported.
- Early, intensive, gait- oriented Task specific training (isokinetic device, treadmill, tilt table) with conventional hospital care may not be beneficial for improving activities of daily living, gait speed, and balance after stroke when compared to Early, intensive traditional physical therapy approach with conventional hospital care or Conventional physical therapy and conventional hospital care or 60min/d, 5d/wk, 5wks.
- BWS treadmill training with Conventional care may be beneficial for improving gait speed, functional mobility, balance, and falls and fear of falling after stroke when compared to Conventional training.

- Forward treadmill with partial BWS treadmill may be beneficial for improving functional mobility, but not biomechanical gait measures, gait speed, and balance, after stroke when compared to Conventional rehabilitation.
- Auditory stimulation with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to 15min rest with High- intensity speed-based treadmill training.
- AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training).
- Inclined treadmill training may be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Treadmill training; the literature is mixed regarding biomechanical gait measures.
- Inclined treadmill training with Rhythmic auditory stimulation may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Inclined treadmill training.
- Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to 15min rest with High- intensity speed-based treadmill training.
- Treadmill training with BWS via overhead harness may not be beneficial for improving functional mobility after stroke when compared to Overground gait training.
- Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.

Summary of Key Points: Treadmill Training

Intervention	Control(s)	Function domain(s)	Effect
Treadmill Training	Conventional Therapy	Aerobic measures, gait endurance	+
Treadmill Training	Conventional Therapy	Biomechanical gait measures, activities of daily living, gait speed, functional mobility, balance, falls and fear of falling, quality of life	–
Treadmill Training	Overground Training	Biomechanical gait measures, range of motion, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, quality of life	–
Treadmill training with Rehabilitation program	Overground gait training with Rehabilitation program	Gait speed, gait endurance	+
Treadmill training with Rehabilitation program	Overground gait training with Rehabilitation program	Biomechanical gait measures	=
Body weight supported Treadmill Training	Conventional Therapy	Motor recovery, gait speed, falls and fear of falling	+
Body weight supported Treadmill Training	Conventional Therapy	Biomechanical gait measures, muscle strength, aerobic measures, activities	–

		of daily living, functional mobility, balance, quality of life	
Body weight supported Treadmill Training	Conventional Therapy	Neurophysiological measures, gait endurance	=
Body weight supported treadmill training	body weight supported treadmill training with Conventional care	Gait speed	–
Body weight supported treadmill training	body weight supported treadmill training with Conventional care	Functional mobility, balance, falls and fear of falling	–
Body weight supported Treadmill Training	Overground Walking	Motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, aerobic measures, sensory and proprioceptive function, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Body weight supported Treadmill Training	Treadmill Training	Biomechanical gait measures, neurophysiological measures, functional mobility	+
Body weight supported Treadmill Training	Treadmill Training	Motor recovery, gait endurance	–
Body weight supported Treadmill Training	Treadmill Training	Gait speed, balance	=
Body weight supported Treadmill Training with Mobility Skills	body weight supported Treadmill Training	Gait speed, gait endurance, balance, falls and fear of falling	–
Body weight supported treadmill with upper extremity ergometry training	Resistive leg cycling with upper extremity ergometry training	Gait speed	+
Body weight supported treadmill with upper extremity ergometry training	Resistive leg cycling with upper extremity ergometry training	Muscle strength, gait endurance	–
Body weight supported treadmill with upper extremity ergometry training	body weight supported treadmill with resistive leg cycling training or body weight supported treadmill with lower extremity progressive resistive exercise	Muscle strength, gait speed, gait endurance	–
Body weight supported Treadmill Training with Facilitation Technique	body weight supported Training with Mechanical Assistance	Motor recovery, biomechanical gait measures, activities of daily living, gait speed	–
Body weight supported Treadmill Training for Different Durations	Home Exercise	Motor recovery, gait speed, gait endurance, balance, falls and fear of falling, quality of life	–
Treadmill Training with Nordic Poles	Treadmill Training	Activities of daily living, gait endurance, functional mobility, balance	+
Treadmill Training with Nordic Poles	Treadmill Training	Gait speed	–
Treadmill Training with Load	Treadmill Training without Load or Conventional Therapy	Motor recovery, biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, activities of daily living, gait speed, falls and fear of falling	–
Treadmill Training with Load	Treadmill Training without Load or Conventional Therapy	Functional mobility	=
Treadmill Training with Incline	Treadmill Training with Decline or Level Treadmill Training	Motor recovery, biomechanical gait measures, muscle strength, spasticity,	–

		activities of daily living, functional mobility, balance	
Treadmill Training with Incline	Treadmill Training with Decline or Level Treadmill Training	Gait endurance	–
Treadmill Training with Incline	Treadmill Training with Decline or Level Treadmill Training	Range of motion, gait speed	=
Treadmill Training with Increased Speed	Treadmill Training with Increased Incline	Biomechanical gait measures, gait speed, gait endurance	+
Treadmill Training with Increased Speed	Treadmill Training with Increased Incline	Balance	–
Constraint Induced Movement with Home Exercise	Treadmill Training	Biomechanical gait measures, functional mobility, balance	–
Treadmill Training with Foot Drop Stimulator	Foot Drop Stimulator	Biomechanical gait measures, spasticity, range of motion, neurophysiological measures, functional mobility	+
Perturbation Treadmill Training	Treadmill Training	Balance	+
Perturbation Treadmill Training	Treadmill Training	Muscle strength, activities of daily living, gait speed, falls and fear of falling	–
Turning Treadmill Training	Treadmill Training	Muscle strength, gait speed, balance	+
Turning Treadmill Training	Treadmill Training	Biomechanical gait measures, biomechanical balance measures	–
Treadmill Training with Mirror Therapy	Treadmill Training	Motor recovery, spasticity, gait speed, gait endurance	–
Treadmill Training with Proprioceptive Neuromuscular Facilitation	Treadmill Training	Gait speed, gait endurance, functional mobility	+
Body weight supported Treadmill Training	Proprioceptive Neuromuscular Facilitation	Biomechanical gait measures, range of motion, activities of daily living, gait speed	–
Treadmill Training with Obstacles	Treadmill Training	Gait endurance, balance	+
Treadmill Training with Obstacles	Treadmill Training	Gait speed, functional mobility, falls and fear of falling	–
Treadmill Training on Unstable Surface	Treadmill Training	Gait endurance, functional mobility	+
Treadmill Training on Unstable Surface	Treadmill Training	Gait speed	–
Treadmill Training with Handrails	Treadmill Training	Biomechanical gait measures	+
Treadmill Training with Horizontal Force	Treadmill Training	Biomechanical gait measures, gait speed, functional mobility	+
Treadmill Training with Horizontal Force	Treadmill Training	Balance	=
Treadmill-based C-Mill (using gait-dependent augmented reality)	Overground walking therapy (walking-adaptability exercises with physical obstacles)	Activities of daily living, gait speed, functional mobility	–
Treadmill Training with virtual reality	Other Training	Biomechanical gait measures, gait speed, functional mobility, balance	+

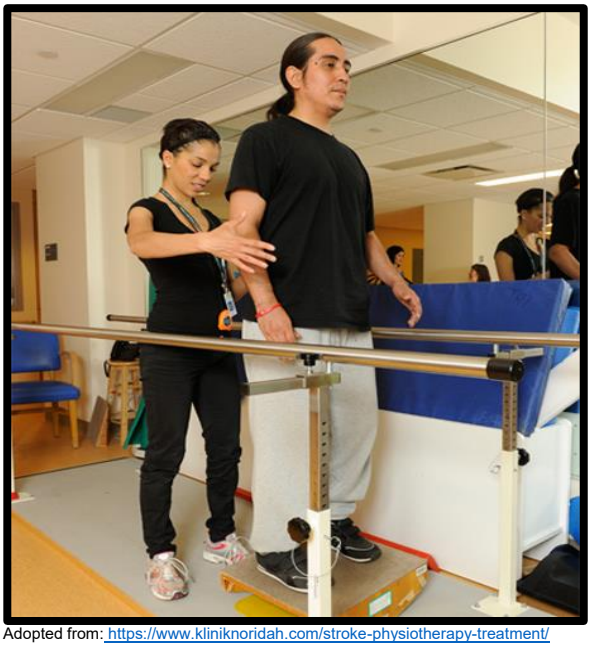
Treadmill Training with virtual reality	Other Training	Biomechanical balance measures	–
Treadmill Training with Smartphone Application	Treadmill Training	Biomechanical gait measures, gait speed	+
Treadmill Training with Visual Deprivation	Treadmill Training	Gait speed	+
Treadmill Training with Visual Deprivation	Treadmill Training	Gait endurance, functional mobility	–
Treadmill Training with Visual Deprivation	Treadmill Training	Biomechanical gait measures	=
Backward Treadmill Training	Treadmill or Conventional Rehabilitation	Biomechanical balance measures, functional mobility	+
Backward Treadmill Training	Treadmill or Conventional Rehabilitation	Motor recovery, biomechanical gait measures, spasticity, gait speed, balance, falls and fear of falling	–
Backward Treadmill Training	Treadmill or Conventional Rehabilitation	Aerobic measures, gait endurance	=
Body weight supported, backward and forward treadmill training	body weight supported, forward treadmill training or body weight supported, backward treadmill training	Biomechanical gait measures	–
Backward treadmill with partial body weight supported	Forward treadmill with partial body weight supported treadmill	Functional mobility	+
Backward treadmill with partial body weight supported	Forward treadmill with partial body weight supported treadmill	Biomechanical gait measures, gait speed, balance	–
Treadmill Training with Overground Training	Home Exercise/ no treatment	Gait speed, gait endurance	+
Treadmill Training with Overground Training	Home Exercise/ no treatment	Biomechanical gait measures, aerobic measures, activities of daily living, functional mobility, balance, falls and fear of falling, quality of life	–
Long-term Treadmill and Overground Walking	Short-term Treadmill and Overground Walking	Gait endurance, functional mobility, quality of life	+
Long-term Treadmill and Overground Walking	Short-term Treadmill and Overground Walking	Biomechanical gait measures, activities of daily living, gait speed	–
High Intensity Treadmill Training	Low Intensity Treadmill Training	Biomechanical gait measures	+
High Intensity Treadmill Training	Low Intensity Treadmill Training	Aerobic measures, gait speed, gait endurance, functional mobility, quality of life	–
Fast Speed Treadmill Training with functional electrical stimulation	Self-selected or Fast Speed Treadmill Training	Gait speed	+
Fast Speed Treadmill Training with functional electrical stimulation	Self-selected or Fast Speed Treadmill Training	Gait endurance	–
Speed Dependent Treadmill Training	Other Treadmill Training	Biomechanical gait measures, gait speed, functional mobility	+
Speed Dependent Treadmill Training	Other Treadmill Training	Balance	–
Body weight supported treadmill training (fast speed)	body weight supported treadmill training (slow speed) or body weight supported treadmill training (variable speed)	Gait speed	–

Speed-dependent Treadmill Training	Task-oriented Training	Functional mobility, balance	–
Error Augmentation Treadmill Training	Treadmill Training	Biomechanical gait measures, gait speed	–
Treadmill Training	Stretching	Aerobic measures, balance	+
Treadmill Training	Stretching	Neurophysiological measures, gait speed, functional mobility	–
Treadmill Training	Stretching	Gait endurance	=
Treadmill Training with Orthotic Devices	Treadmill Training	Motor recovery, biomechanical gait measures, gait speed, functional mobility	+
Treadmill Training with Orthotic Devices	Treadmill Training	Balance	=
Electromechanical gait trainer therapy with Conventional rehabilitation	Body weight-supported treadmill training with Conventional rehabilitation	Functional mobility	+
Electromechanical gait trainer therapy with Conventional rehabilitation	Body weight-supported treadmill training with Conventional rehabilitation	Motor recovery, spasticity, gait speed	–
Treadmill Training with Action Observation	Treadmill Training	Biomechanical gait measures, gait speed, gait endurance, functional mobility	+
Circular treadmill training with ambulation training	Regular treadmill training+ ambulation training	Biomechanical gait measures, neurophysiological measures, gait speed	+
Overground gait training + visual cue feedback	Standard physiotherapy	Motor recovery, biomechanical gait measures, gait speed, functional mobility, balance, falls and fear of falling, quality of life	–
Treadmill walking training + conventional PT	conventional PT	Gait speed, gait endurance	–
Augmented reality treadmill-based gait adaptation training	Treadmill training with overground walking	Functional mobility, balance	+
Augmented reality treadmill-based gait adaptation training	Treadmill training with overground walking	Gait speed	=
Rhythmic Auditory Stimulation with Custom Physiotherapy program and Treadmill gait training	Custom physiotherapy program with Treadmill gait training	Gait speed, functional mobility	+
Rhythmic Auditory Stimulation with Custom Physiotherapy program and Treadmill gait training	Custom physiotherapy program with Treadmill gait training	Biomechanical gait measures	=
Treadmill training with HEALBOT exoskeleton	Treadmill training	Neurophysiological measures, functional mobility	+
Treadmill training with HEALBOT exoskeleton	Treadmill training	Balance	–
Treadmill training with HEALBOT exoskeleton	Treadmill training	Biomechanical gait measures, gait speed	=
Functional electrical stimulation with treadmill training	Treadmill training	Gait endurance, functional mobility	+

Functional electrical stimulation with treadmill training	Treadmill training	Gait speed	–
Anodal transcranial direct current stimulation with Treadmill training	Sham transcranial direct current stimulation with Treadmill training	Biomechanical gait measures, range of motion, gait speed	–
Bilateral transcranial direct current stimulation and Treadmill	Sham transcranial direct current stimulation with Treadmill	Motor recovery, biomechanical gait measures, neurophysiological measures, gait speed, functional mobility	–
Bilateral transcranial direct current stimulation and Treadmill	Cathodal transcranial direct current stimulation and Treadmill	Motor recovery, biomechanical gait measures, neurophysiological measures, gait speed	+
Bilateral transcranial direct current stimulation and Treadmill	Cathodal transcranial direct current stimulation and Treadmill	Functional mobility	–
Bilateral transcranial direct current stimulation and Treadmill	Sham transcranial direct current stimulation with Treadmill	Motor recovery, biomechanical gait measures, functional mobility	–
Bilateral transcranial direct current stimulation and Treadmill	Sham transcranial direct current stimulation with Treadmill	Neurophysiological measures, gait speed	–
Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training)	Sham taping with exercise training	Biomechanical gait measures, gait speed, gait endurance, balance, falls and fear of falling	–
Underwater Treadmill gait training with conventional rehabilitation	Overground gait training with conventional rehabilitation	Biomechanical gait measures	–
Underwater Treadmill gait training with conventional rehabilitation	Overground gait training with conventional rehabilitation	Gait speed	=
Functional electrical stimulation with treadmill gait training	Sham Functional electrical stimulation with treadmill gait training	Motor recovery, biomechanical gait measures, gait speed, functional mobility	+
Bicephalic Transcranial direct-current stimulation with Footdrop stimulator and Treadmill gait training	Sham transcranial direct-current stimulation with Footdrop stimulator and treadmill gait training	Spasticity, gait endurance, functional mobility, quality of life	–
Body weight supported treadmill training (BWST) with conventional rehabilitation	Overground gait training with conventional rehabilitation	Biomechanical gait measures, gait speed, functional mobility, balance	+
Dual-task gait training with treadmill	Single-task gait training with treadmill	Gait speed	+
Dual-task gait training with treadmill	Single-task gait training with treadmill	Biomechanical gait measures, functional mobility, falls and fear of falling	–
Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training	Sham Combined aerobic and resistance training with Sham Cognitive training	Gait speed, gait endurance, functional mobility, quality of life	–
Treadmill training using insole on less affected side	Treadmill training	Biomechanical gait measures, gait speed, gait endurance, functional mobility	+
Gait training with Gait Exercise Assist Robot (GEAR)	Gait training with treadmill	Functional mobility	+
Gait training with Gait Exercise Assist Robot (GEAR)	Gait training with treadmill	Biomechanical gait measures, gait speed, quality of life	–
Gait training with Gait Exercise Assist Robot (GEAR)	Gait training with treadmill	Gait endurance	=

High frequency repetitive transcranial magnetic stimulation with Treadmill Training	Sham repetitive transcranial magnetic stimulation with Treadmill Training	Gait speed, gait endurance, functional mobility	+
Cerebellar transcranial direct current stimulation with split-belt treadmill training	Sham cerebellar transcranial direct current stimulation with split-belt treadmill training	Biomechanical gait measures, gait speed	–
Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training)	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training)	Motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training)	15min rest with High- intensity speed-based treadmill training	Motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling	–
Backward treadmill training with botulinum toxin type A therapy	forward treadmill training with botulinum toxin type A therapy	Biomechanical balance measures, gait speed	+
Backward treadmill training with botulinum toxin type A therapy	forward treadmill training with botulinum toxin type A therapy	Biomechanical gait measures, spasticity	–
High-Intensity Interval Training – Treadmill	Moderate-intensity Continuous Exercise - Treadmill	Neurophysiological measures	+
High-Intensity Interval Training – Treadmill	Moderate-intensity Continuous Exercise - Treadmill	Gait speed	=
Dual-task (virtual reality-based UL training while walking on treadmill)	Single task treadmill walking	Gait speed, balance, falls and fear of falling	+
Dual-task (virtual reality-based UL training while walking on treadmill)	Single task treadmill walking	Functional mobility	–
Treadmill Training with Mirror Therapy	Treadmill Training with Sham	Motor recovery, spasticity, gait speed, gait endurance	–
Gait training program (treadmill + overground walking) wearing a hip-assist robot	Gait training (treadmill training + over ground walking)	Motor recovery, biomechanical gait measures, muscle strength, gait speed, falls and fear of falling	+
Gait training program (treadmill + overground walking) wearing a hip-assist robot	Gait training (treadmill training + over ground walking)	Balance	–
Hybrid Assistive Limb (HAL) exoskeleton with Bodyweight supported treadmill training	Conventional Physical therapy	Gait speed, gait endurance, functional mobility, balance	–
High Frequency repetitive transcranial magnetic stimulation (5Hz) with Treadmill Training	Sham repetitive transcranial magnetic stimulation with Treadmill Training	Motor recovery, gait speed	+
High Frequency repetitive transcranial magnetic stimulation (5Hz) with Treadmill Training	Sham repetitive transcranial magnetic stimulation with Treadmill Training	Neurophysiological measures	–
Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT)	Sham taping with treadmill training	Gait endurance, functional mobility	+
Body weight support treadmill training with visual biofeedback	Body weight support treadmill training	Gait endurance	+

Body weight support treadmill training with visual biofeedback	Body weight support treadmill training	Biomechanical gait measures, functional mobility	–
Body weight support treadmill training with visual biofeedback	Body weight support treadmill training	Gait speed	=
Water-based aerobic exercise on a motorized aquatic treadmill with Conventional rehabilitation therapy	Aerobic Exercise (by upper and lower body ergometers) with Conventional rehabilitation therapy	Motor recovery, aerobic measures, activities of daily living, balance, quality of life	–
Water-based aerobic exercise on a motorized aquatic treadmill with Conventional rehabilitation therapy	Aerobic Exercise (by upper and lower body ergometers) with Conventional rehabilitation therapy	Muscle strength	=
Aquatic-based treadmill aerobic training with conventional care	Land-based aerobic exercises on cycle ergometer with conventional care	Aerobic measures	+
Aquatic-based treadmill aerobic training with conventional care	Land-based aerobic exercises on cycle ergometer with conventional care	Activities of daily living, gait endurance	–
Rhythmic auditory stimulation with treadmill training and conventional physical therapy	Treadmill training with conventional physical therapy	Gait endurance	+
Rhythmic auditory stimulation with treadmill training and conventional physical therapy	Treadmill training with conventional physical therapy	Biomechanical gait measures, biomechanical balance measures	–
Rhythmic auditory stimulation with treadmill training and conventional physical therapy	Treadmill training with conventional physical therapy	Gait speed	=
Rhythmic auditory stimulation with treadmill training and conventional physical therapy	Neurodevelopmental treatment with conventional physical therapy	Biomechanical balance measures, gait endurance	–
Rhythmic auditory stimulation with treadmill training and conventional physical therapy	Neurodevelopmental treatment with conventional physical therapy	Biomechanical gait measures, gait speed	=
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy	Motor recovery, muscle strength	+
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy	Activities of daily living, gait speed, functional mobility, balance	–
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Conventional physical therapy with treadmill training	Motor recovery, gait speed, muscle strength	+
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Conventional physical therapy with treadmill training	Activities of daily living	–
Body weight supported treadmill training with anodal transcranial direct current stimulation	Body weight supported treadmill training with sham transcranial direct current stimulation	Gait speed	+
Body weight supported treadmill training with anodal transcranial direct current stimulation	Body weight supported treadmill training with sham transcranial direct current stimulation	Motor recovery, balance	–
Body weight supported treadmill training with anodal transcranial direct current stimulation	Body weight supported treadmill training with sham transcranial direct current stimulation	Functional mobility	=



Whole body vibration with Treadmill training	Exercises on platform without vibration with Treadmill training	Biomechanical gait measures, gait speed	+
Whole body vibration with Treadmill training	Exercises on platform without vibration with Treadmill training	Gait endurance	–
High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc)	Conventional physical therapy care	Gait speed, quality of life	+
High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc)	Conventional physical therapy care	Functional mobility, balance, falls and fear of falling	–
High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc)	Conventional physical therapy care	Biomechanical gait measures, gait endurance	=
Treadmill training with visual biofeedback and physiotherapy exercises	Treadmill training with physiotherapy exercises	Biomechanical gait measures, range of motion	–
Treadmill training with Gait Trainer 2 Biodex biofeedback (30-45min/d) with Conventional individual exercises	Treadmill training without biofeedback with Conventional individual exercises	Biomechanical balance measures, functional mobility, balance	–
Aquatic therapy (physical therapy exercises) with aquatic treadmill	Conventional physical therapy exercise with land-based treadmill	Activities of daily living, functional mobility	+
Aquatic therapy (physical therapy exercises) with aquatic treadmill	Conventional physical therapy exercise with land-based treadmill	Spasticity, neurophysiological measures	–
Aquatic therapy (physical therapy exercises) with aquatic treadmill	Conventional physical therapy exercise with land-based treadmill	Muscle strength, range of motion	=
Treadmill training with Rhythmic auditory stimulation	Treadmill training	Biomechanical gait measures, gait speed, functional mobility, gait endurance, balance	+
Treadmill training with Rhythmic auditory feedback	Treadmill training	Biomechanical gait measures, gait speed, functional mobility	+
Inclined treadmill training with Rhythmic auditory stimulation	Treadmill training	Biomechanical gait measures, gait speed, gait endurance, functional mobility, balance	+
Virtual reality treadmill training-based community ambulation	Community ambulation training	Biomechanical gait measures, gait speed, gait endurance, functional mobility, falls and fear of falling	–
Virtual reality treadmill training-based community ambulation	Conventional rehabilitation	Functional mobility, falls and fear of falling	+
Virtual reality treadmill training-based community ambulation	Conventional rehabilitation	Biomechanical gait measures, gait speed, gait endurance	–
Treadmill training with Virtual reality and Ankle robotics	Seated training with Virtual reality and Ankle robotics	Biomechanical gait measures, biomechanical balance measures, range of motion, gait speed	–
Task-oriented treadmill training with conventional therapy	Treadmill training with conventional therapy	Biomechanical gait measures, gait speed, gait endurance, functional mobility	+
Partial body-weight support treadmill training with Visual biofeedback	Partial body-weight support treadmill training	Biomechanical gait measures, range of motion	–

Treadmill training with visual biofeedback and basic physiotherapy	Treadmill training with basic physiotherapy	Biomechanical gait measures, activities of daily living, gait speed, gait endurance, functional mobility	–
Cognitive-motor dual task training while treadmill walking with Conventional rehabilitation	Single task training on Treadmill walking with Conventional rehabilitation	Gait speed	+
Cognitive-motor dual task training while treadmill walking with Conventional rehabilitation	Single task training on Treadmill walking with Conventional rehabilitation	Functional mobility	–
Treadmill training with Rhythmic auditory stimulation	Overground training with Rhythmic auditory stimulation	Gait speed, gait endurance, functional mobility	+
Treadmill training with Rhythmic auditory stimulation	Overground training with Rhythmic auditory stimulation	Biomechanical gait measures	=
Treadmill training with Virtual reality	Conventional rehabilitation	Biomechanical balance measures	+
Treadmill training with functional electrical stimulation on gluteus medius and tibialis anterior	Treadmill training	Gait speed	+
Treadmill training with functional electrical stimulation on gluteus medius and tibialis anterior	Treadmill training	Biomechanical gait measures, muscle strength	=
Treadmill training with functional electrical stimulation on gluteus medius and tibialis anterior	Treadmill training	Gait endurance, balance	–
Treadmill training with Tilt sensor functional electrical stimulation with conventional physical therapy	Treadmill training with Placebo Tilt sensor functional electrical stimulation with conventional physical therapy	Gait speed, functional mobility, balance	+
Treadmill training with Tilt sensor functional electrical stimulation with conventional physical therapy	Treadmill training with Placebo Tilt sensor functional electrical stimulation with conventional physical therapy	Muscle strength	–
Overground gait training with ankle mass	Overground gait training without mass or Treadmill gait training without mass	Biomechanical gait measures, range of motion, gait speed	–
Body Weight-Supported Treadmill Training with functional electrical stimulation	Body Weight Supported Treadmill Training	Biomechanical gait measures, gait speed, functional mobility, balance	+
Underwater treadmill walking	Overground treadmill walking	Biomechanical gait measures, neurophysiological measures	+
Underwater treadmill walking	Overground treadmill walking	Functional mobility	–
Treadmill training with Virtual reality	Treadmill training	Gait speed	+
Treadmill with optic flow with conventional physical therapy	Treadmill with conventional physical therapy	Gait speed, gait endurance, functional mobility	+
Treadmill with optic flow with conventional physical therapy	Treadmill with conventional physical therapy	Balance	–
Treadmill with optic flow with conventional physical therapy	Conventional therapy	Balance	+
Aerobic training (treadmill and cycle ergometer)	Conventional rehabilitation	Aerobic measures, gait endurance, functional mobility, balance	–

Treadmill training with Virtual reality and Conventional rehabilitation	Treadmill training with Conventional rehabilitation	Biomechanical gait measures, biomechanical balance measures, functional mobility	–
Aerobic training (cycle ergometer, treadmill, balance)	Conventional rehabilitation	Aerobic measures, activities of daily living	+
Treadmill training with Virtual reality	Treadmill training	Functional mobility, falls and fear of falling	=
Specialized task oriented locomotor training (includes using Tilt table, limb-load monitor, isokinetic device and treadmill training) with Conventional physiotherapy	Conventional physiotherapy	Motor recovery, activities of daily living, gait speed, functional mobility, balance	–
Treadmill training with Virtual reality	Stepping over real objects on 10m walkway	Motor recovery, biomechanical gait measures, gait endurance, functional mobility	–
Treadmill training and overground gait training	Placebo program of low- intensity home exercise program with Telerehabilitation	Gait speed, gait endurance	+
Treadmill training and overground gait training	Placebo program of low- intensity home exercise program with Telerehabilitation	Quality of life	–
Treadmill training and overground gait training	Placebo program of low- intensity home exercise program with Telerehabilitation	Biomechanical gait measures	=
Baseline conventional therapy with Treadmill training with partial body weight supported and Individual physical therapy	Baseline conventional therapy with Treadmill training with partial body weight supported	Functional mobility	+
Baseline conventional therapy with Treadmill training with partial body weight supported and Individual physical therapy	Baseline conventional therapy with Treadmill training with partial body weight supported	Motor recovery, gait speed	–
Early, intensive, gait- oriented Task specific training (isokinetic device, treadmill, tilt table) with conventional hospital care	Early, intensive traditional physical therapy approach with conventional hospital care or Conventional physical therapy and conventional hospital care or 60min/d, 5d/wk, 5wks	Activities of daily living, gait speed, balance	–
BWS treadmill training with Conventional care	Conventional training	Gait speed, functional mobility, balance, falls and fear of falling	+
Forward treadmill with partial BWS treadmill	Conventional rehabilitation	Functional mobility	+
Forward treadmill with partial BWS treadmill	Conventional rehabilitation	Biomechanical gait measures, gait speed, balance	–
Auditory stimulation with robot-assisted gait training (Treadmill) with conventional physical therapy	Conventional physical therapy with treadmill training	Muscle strength	+
Treadmill with optic flow with conventional physical therapy	Conventional therapy	Gait speed, gait endurance, functional mobility	=
AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training)	15min rest with High- intensity speed-based treadmill training	Motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–

AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training)	Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training)	Motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	−
Inclined treadmill training	Treadmill training	Biomechanical gait measures	=
Inclined treadmill training	Treadmill training	Gait speed, gait endurance, functional mobility, balance	+
Inclined treadmill training with Rhythmic auditory stimulation	Inclined treadmill training	Biomechanical gait measures, gait speed, gait endurance, functional mobility, balance	+
Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training)	15min rest with High- intensity speed-based treadmill training	Motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	−
Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training)	15min rest with High- intensity speed-based treadmill training	Quality of life	+
Treadmill training with BWS via overhead harness	Overground gait training	Functional mobility	−
Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy	Conventional physical therapy with treadmill training	Muscle strength	+

Physiotherapy and Exercise Programs

Adopted from: https://www.kliniknoridah.com/stroke-physiotherapy-treatment/

Exercise can be defined as planned physical activity that is structured and repetitive and is performed deliberately with the intention of improving physical fitness. Major factors of physical fitness are cardiovascular fitness, strength and power. After a stroke, individuals are impaired in all three of these attributes, to significant but varying degrees (Saunders et al., 2014). Physiotherapy and exercise are the primary method for regaining any of these deficits

experienced after the injury. Although it is well known that physiotherapy and exercise are effective for rehabilitation, it is still not clear as to what type is most effective (Cho & Cha, 2016; Langhorne et al., 1996). Therefore, there is always an effort to identify when, where and how physiotherapy should be applied to maximize its benefit to the patient's recovery. Besides the more obvious physical benefits associated with exercise, psycho-social benefits also exist, and attempts are made to maximize these residual benefits as well (Saunders et al., 2014).

A total of 84 RCTs were found that evaluated physiotherapy and exercise programs for lower extremity motor rehabilitation. One RCT compared Body Weight Shift Technique with Conventional Therapy (Krishna et al. 2018). One RCT compared Neurorestoration Protocol Physiotherapy with Conventional Physiotherapy (Rahayu et al. 2020). One RCT compared Leisure-time Physical Activity with Nonleisure-time Physical Activity (Ashizawa et al. 2021). One RCT compared Self-regulation Rehabilitation with Conventional Therapy (Liu et al. 2014). One RCT compared Range of Motion / mobilization Exercise with Conventional Therapy (Tseng et al. 2007). One RCT compared Agility Exercise with Stretching (Marigold et al. 2005). Two RCTs compared Physio equipment with Conventional Therapy (Huang et al. 2022a; Gul et al. 2021). One RCT compared Cross-training Physiotherapy with Conventional Physiotherapy (Park et al. 2021b). Seventeen RCTs compared Early Rehabilitation Programs with Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke (Garcia-Perez et al. 2024; Xu 2022; Ning et al. 2022; Wang et al. 2022b; Liu et al. 2021b; Yen et al. 2020; Wu et al. 2020a; Wu et al. 2020b; Yu et al. 2020b; Rahayu et al. 2019; Pan 2018; Langhorne et al. 2017; Yelnik et al. 2017; Bernhardt et al. 2015; Bai et al. 2012; Fang et al. 2003; Wade et al. 1992). Two RCTs compared Physical Therapy with No Treatment (Hoseinabadi et al. 2013; Werner et al. 1996). One RCT compared Occupational Therapy with No Treatment (Logan et al. 2004). Eight RCTs compared Custom Exercise Programs with Conventional Therapy (Swank et al. 2020; Xia et al. 2020; Medina-Rincon et al. 2019; Askim et al. 2018; Sackley et al. 2015; Askim et al. 2010; Allen et al. 2009; Werner et al. 2002a). One RCT compared Aerobic and Resistance Training with Aerobic Training (Marzolini et al. 2018). Two RCTs compared Aerobic and Resistance Training with Conventional Care (Rizvi et al. 2023; Lee et al. 2015d). Two RCTs compared Closed Chain Exercise with Open Chain Exercise or Standard Rehabilitation (Krawczyk et al. 2014; Lee et al. 2013f). Three RCTs compared Sling Exercise Therapy with Conventional Therapy (Wang et al. 2022a; Liu et al. 2020; Lou et al. 2019). Two RCTs compared Aerobic Exercise with Cognitive Training with Nonaerobic Exercise with Unstructured Mental Activities or Sham (Koch et al. 2020; Yeh et al. 2019). One RCT compared Virtual Reality Exercise Program with Customized Physiotherapy or Conventional Physiotherapy (Cannell et al. 2018). One RCT compared High-intensity Functional Exercise Program with Education (Holmgren et al. 2010). One RCT compared High Repetitive Weight Bearing Exercises with Low Repetitive Weight Bearing Exercises (Agarwal et al. 2008). Eleven RCTs compared Higher Intensity Training with Lower Intensity Training or Conventional Care (Chen et al. 2024a; Moncion et al. 2024; Marzolini et al. 2023; Reynolds et al. 2021; Gjellesvik et al. 2021; Boyne et al. 2019; Hornby et al. 2019; Hornby et al. 2016; Boyne et al. 2016; Langhammer et al. 2008; Sivenius et al. 1985). Four RCTs compared Increased Duration of Exercise with Conventional Care/Exercise (Klassen et al. 2020; Hesse et al. 2011; Glasgow Augmented Physiotherapy Study GAPS group 2004; Partridge et al. 2000). Four RCTs compared Community-based Physical Activity with No Intervention (Kang et al. 2023; Aravind et al. 2022; Marsden et al. 2010; Green et al. 2002). Four RCTs compared Community-based Exercise Program with Other Care (Nindorera et al. 2023; Stuart et al. 2019; Harrington et al. 2010; Olney et al. 2006). Two RCTs compared Community-based Exercise Program with Upper Extremity Exercise Program (Dean et al. 2012; Pang et al. 2005). One RCT compared Non-Paretic Side Training with Conventional Therapy (Pandian et al. 2014). One RCT compared Falls Prevention Program with Usual Care (Batchelor et al. 2012). One RCT compared Skating Exercise with Treadmill Training (Soh et al. 2020). One RCT compared High-Intensity Training with Acute Intermittent Hypoxia with High-Intensity Training Alone (Hornby et al. 2024). One RCT compared Implicit Motor Learning with Conventional Therapy (Johnson et al. 2024). One RCT compared Aerobic Exercise with Task-Specific Training with Task-Specific Training Alone (Linder et al. 2024). One RCT compared Motivational Interviewing with Occupational Therapy with Occupational Therapy Alone (Gholipour et al. 2024).

The methodological details and results of all 84 RCTs are presented in Table 10.

Table 10. RCTs Evaluating Physiotherapy and Exercise Programs for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)

Body Weight Shift Technique vs Conventional Therapy		
Krishna et al. (2018) RCT (8) Nstart=30 Nend=30 TPS=Not reported A vs B	E: Body weight shift technique induced by shoe lift on unaffected side C: No shoe lift technique Duration: 2wks	E vs C: Fugl Meyer Assessment (-) Weight Bearing on affected side (+exp) 10-Meter Walk Test (+exp) Berg Balance Scale (+exp) Lower extremity functional performance (+exp)
Neurorestoration Protocol Physiotherapy vs Conventional Physiotherapy		
Rahayu et al. (2020) RCT (8) Nstart=67 Nend=64 TPS=Acute A vs 0	E: Neurorestoration protocol Physiotherapy C: Conventional Physiotherapy Duration: 60min/d, 7d/wk, for 1wk	E vs C: Brain-derived neurotropic factor (BDNF) biomarker (-) Berg Balance Scale (+exp) Barthel Index (+exp)
Leisure-time Physical Activity vs Nonleisure-time Physical Activity		
Ashizawa et al. (2021) RCT (4) Nstart=45 Nend=33 TPS=Acute A1 vs A2	E: Nonleisure-time physical activity guidance (NLTPAG) C: Leisure-time physical activity guidance Duration: 20min/d, 2d/wk guidance program during hospitalization, 30-40min/d at- home activity for 3mo after discharge	E vs C: Physical activity level (-) Low intensity (-) Moderate Intensity (-) Sedentary Behavior Time (-) 6-min walking distance (-) 30s chair stand test (-) Self-Efficacy for Physical Activity (-)
Self-regulation Rehabilitation vs Conventional Therapy		
Liu et al. (2014) RCT (7) Nstart=46 Nend=44 TPS=Acute A vs 0	E: Self-regulation rehabilitation + physical therapy C: Conventional occupational + physical therapy Duration: 60min/d, 5d/wk, for 1wk intervention sessions & 60min/d physical therapy	E vs C: Functional Independence Measure Motor (+exp) Cognitive (-) Fugl-Meyer Assessment Lower extremity (-) Upper extremity (-) Color Trails Test (-)
Range of Motion / mobilization Exercise vs Conventional Therapy		
Tseng et al. (2007) RCT (6) Nstart=65 Nend=59 TPS=Chronic A vs B vs 0	E1: Range of Motion exercise program by themselves E2: Range of Motion exercise program with physical help C: Usual care Duration: 20-40min/d, 6d/wk, for 4wks ROM exercise	E1/E2 vs C: functional independence (+exp1, +exp2) joint angle (+exp1, +exp2) self-reported pain (+exp1, +exp2) Geriatric Depression Scale -Short Form (+exp1, +exp2) E1 vs E2: functional independence (-) joint angle Shoulder-all directions (exp2) Elbow flexion (+exp2) Elbow Extension (-) Wrist (+exp2) Hip- all directions (+exp2) knee (flexion) (+exp2) knee (Extension) (-) Ankle Dorsal flexion (-)

		Ankle Plantar flexion/eversion/inversion (+exp2) self-reported pain (-) Geriatric Depression Scale -Short Form (-)
Agility Exercise vs Stretching		
Marigold et al. (2005) RCT (6) Nstart=61 Nend=48 TPS=Chronic A vs B	E: Agility exercises C: Stretching and weight-shifting Duration: 60min/d, 3d/wk for 10wks	E vs C: Berg Balance Scale (-) Timed Up and Go(-) step reaction time (+exp) Activity-specific balance confidence (-) Nottingham Health profile (-) Posural reflex onset latency Paretic tibialis anterior (-) paretic rectus femoris (+exp) paretic medial head of gastrocnemius (-) paretic biceps femoris (-) Non-Paretic tibialis anterior (-) Non-paretic rectus femoris (-) Non-paretic medial head of gastrocnemius (+exp) Non-paretic biceps femoris (-)
Physio equipment vs Conventional Therapy		
Huang et al. (2022a) RCT (4) Nstart=38 Nend=32 TPS=Chronic A vs 0	E: Stepper-based training C: Conventional therapy Duration: 35 mins/d, 2-4ds/wk, 36 sessions	E vs C: VO2 peak (+exp) Peak work rate (+exp) Expiratory volume peak (+exp) Heart rate peak (-) Heart rate at rest (-) Oxygen uptake efficiency slope (-) Peak RER (-) Resting systolic blood pressure (+exp) Resting diastolic blood pressure (+exp) Peak systolic blood pressure (-) Peak diastolic blood pressure (-)
Gul et al. (2021) RCT (3) Nstart=40 Nend=40 TPS=Subacute A vs 0	E: Swiss ball exercises + Conventional Treatment C: Conventional training Duration: 60mins/d, 4d/wk, for 3wks	E vs C: Berg Balance Scale (+exp) Trunk Impairment Scale (+exp)
Early Rehabilitation Programs vs Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke		
Garcia-Perez et al. (2024) RCT (8) Nstart=62 Nend=60 TPS=Acute A vs 0	E: Early Occupational Therapy Program (EOTIPS) + conventional rehabilitation C: Conventional rehabilitation Duration: E: 60min inpatient OT + 120min OT at home, then 60min after 1mo; C: 30min/d inpatient physiotherapy + 45min/d, 2-3d/wk outpatient physiotherapy	E vs C: Spanish stroke and aphasia quality of life (+exp) Barthel Index (-) Modified Rankin Scale (-) MOCA (+exp) BBS (-) TUG(-) FMA-UE (-) SIS (-)

		Communicative Activity Log (-) Beck Depression Inventory (+exp) Hamilton anxiety scale (-)
Xu (2022) RCT (4) Nstart=160 Nend=160 TPS=Acute A vs B	E: Conventional stroke medication + Early rehabilitation exercise training (48-72h after stroke) C: Conventional stroke medication Duration: 30-45min/d, 4-6d/wk, for 4wks	E vs C: Fugl-Meyer score (+exp) Barthel Index score (+exp)
Ning et al. (2022) RCT (6) Nstart=70 Nend=70 TPS=Acute A vs 0	E: Early rehabilitation (language, motor, cognitive, daily life nursing) C: Conventional therapy Duration: NR	E vs C: Rehabilitation enthusiasm (+exp) NIH Stroke Scale (+exp) Barthel index (+exp) Berg Balance scale (+exp) Fugl-Meyer assessment (+exp) Nursing satisfaction (+exp)
Wang et al. (2022b) RCT (7) Nstart=120 Nend=115 TPS=Acute A vs B	E1: Early Conventional therapy (after 24-48 hours); E2: Late Conventional therapy (72-96 hours post stroke) Duration: 40 mins/d, 7ds/wk, 12wks (Control group loses 2 days in the first week)	E1 vs E2: modified Rankin Scale (+exp) FMA-UE (-) FMA-LE (+exp) Simple effects of therapeutic interventions (+exp)
Liu et al. (2021b) RCT (5) Nstart=90 Nend=88 TPS=Acute A1 vs A2	E: Ultra early rehabilitation program (started within 72 hours of onset) C: Early rehabilitation program (started from 72 hours to 7 days after onset) Duration: 20-30min/d, 2- 3sessions/d, 4-5d/wk, for 12wks	E vs C: National Institutes of Health Stroke Scale (+exp) Modified Barthel Index (+exp) Fugl-Meyer Assessment (+exp)
Yen et al. (2020) RCT (8) Nstart=60 Nend=60 TPS=Acute A vs B	E: Early Mobilization C: Standard Early Rehabilitation Duration: 30min/wk, 5d/wk till discharge	E vs C: FIM Motor (+exp) Self-care (+exp) Transfers and locomotion (+exp) PASS (-) FAC (+exp)
Yu et al. (2020b) RCT (3) Nstart=82 Nend=82 TPS=Acute A vs B	E: Early Interventional Rehabilitation (2-7 days Post Stroke) C: Late interventional Rehabilitation (3-4 wks Post Stroke) Duration: 45min/d, patient- dependant	E vs C: Fugl-Meyer Assessment (+exp) Barthel Index (+exp) Neurological deficit score (+exp)
Rahayu et al. (2019) RCT (6) Nstart=40 Nend=40 TPS=Acute A1 vs A2	E: Early mobilization training starting at 24h poststroke diagnosis C: Early mobilization training starting at 48h poststroke diagnosis Duration: 30-60min/d for 7d - 24h mobilization, 30-60min/d for 6d - 48h mobilization	E vs C: Berg Balance scale (+exp) Barthel index (+exp)
Pan (2018) RCT (5) Nstart=86 Nend=86	E: Early rehabilitation therapy + routine primary therapy C: Routine Primary Therapy	E vs C: Fugl-Meyer Assessment (+exp) Neurologic Deficit Scale (+exp) Barthel Index (+exp)

TPS=Acute A vs B	Duration: 30 - 60 min/d, 2sessions/d, for 50 days	Clinical Efficacy (+exp) Satisfaction (+exp)
Langhorne et al. (2017) RCT (8) Nstart=2104 Nend=2083 TPS=Acute A vs 0	E: Very early mobilization C: Conventional rehabilitation Duration: 3mo	E vs C: Modified Rankin Scale (+con) 50 Meter Walking (-)
Yelnik et al. (2017) RCT (7) Nstart=104 Nend=82 TPS=Acute A vs B	E: Early and intensive Physiotherapy C: Soft (passive) Physiotherapy Duration: 15 - 20min/d, 5d/wk Soft PT & 45min/d, 5d/wk Intensive PT for 3mo	E vs C: Fugl-Meyer Assessment (-) Postural Assessment Scale for Stroke (-) Days (no) to walk 10 m (-) Modified Rankin Scale (-) Functional Independence Measurement (-) Stroke impact scale (-)
Bernhardt et al. (2015) RCT (8) Nstart=2104 Nend=2083 TPS=Acute A vs 0	E: Early mobilization after stroke C: Conventional rehabilitation Duration: 14d or until discharge	E vs C: Mortality (-) Adverse Effect (-) Favourable Outcome (+con) Modified Rankin Scale (-) Walk 50m Unassisted (-)
Bai et al. (2012) RCT (5) Nstart=364 Nend=345 TPS=Acute A vs 0	E: Early 3-stage ADL-focused rehabilitation plan + Conventional Care C: Conventional care Duration: First stage: 45min/d, 5d/wk, 1mo, Second stage: 2mo, Third stage: 3 mo; Total of 6mo	E vs C: Fugl-Meyer Assessment (+exp) Modified Barthel Index (+exp)
Fang et al. (2003) RCT (6) Nstart=156 Nend=128 TPS=Acute A vs B	E: Early physical therapy during hospitalization C: Conventional hospitalization care Duration: 45min/d, 5d/wk, for 4wks physical therapy	E vs C: Glasgow Coma Scale (-) Mini-Mental State Examination (-) Clinical Neurological Deficit Scale (-) Fugl-Meyer Assessment (-) Modified Barthel Index (+exp)
Wade et al. (1992) RCT crossover (6) Nstart=94 Nend=89 TPS=Chronic A1 vs A2	E: Early individualized physiotherapy program (education and exercise) C: Late individualized physiotherapy program (education and exercise) Duration: 1-11session/12wks	E vs C: 10 m walk time at crossover time (+exp) at the end of 2 phases (+con) Rivermead motor assessment (-) Barthel index (-) Frenchay activities index (-) Rivermead mobility index (-) Nottingham extended activities of daily living index (-) Hospital anxiety depression scale (-) Nine hole peg test (-)
Physical Therapy vs No Treatment		
Hoseinabadi et al. (2013) RCT (4) Nstart=24 Nend=24 TPS=Chronic	E: Practical Physical therapy C: No treatment Duration 60min/d, 3d/wk, for 4wks	E vs C: Berg Balance Scale (+exp) Barthel Index (+exp) Modified Ashworth Scale (+exp)

A vs 0		
Werner et al. (1996) RCT (4) Nstart=49 Nend=40 TPS=Chronic A vs 0	E: Intensive outpatient rehabilitation program (physical + occupational therapy) C: No treatment Duration: 120min/d, 4d/wk, for 12wks	E vs C: Functional Independence Measure (+exp) Jepsen hand function evaluation (-) Brunnstrom's motor rating (-) timed evaluation of stair climbing (-) walking speed (-) Sickness Index Profile (+exp) Beck's Depression Scale (-)
Occupational Therapy vs No Treatment		
Logan et al. (2004) RCT (7) Nstart=168 Nend=168 TPS=Chronic A1 vs A2	E: Occupational Therapy + Leaflets for local transport C: Leaflets for local transport Duration: 7 sessions over 3mth	E vs C: Nottingham Extended Activities of Daily Living (+exp) General Health Questionnaire-12 (-)
Custom Exercise Programs vs Conventional Therapy		
Swank et al. (2020) RCT (7) Nstart=73 Nend=73 TPS=Acute A vs 0	E: Patient Directed Activity Program (PDAP) + Conventional Care C: Conventional Care A Duration: 3h/d, 7d/wk for 1mo (on average) Usual care & 60min/d, 7d/wk Patient-directed Activity	E vs C: steps/day (+exp) Stroke Rehabilitation Assessment of Movement Measure (-) Functional Independence measure (-) Stroke Impact scale memory and thinking (+exp) communication (+exp) recovery from stroke (+exp) physical problems (+exp) mobility in home and community (+exp) Mood (-) Daily activities (-) Use of hand (-)
Xia et al. (2020) RCT (8) Nstart=285 Nend=259 TPS=Acute A vs 0	E: Customized Tiered Conventional Therapy C: Conventional rehabilitation Duration: 3wks	E vs C: Modified Barthel Index (+exp) Fugl-Meyer Assessment (-) Stroke-Specific Quality-of-life Scale (-)
Medina-Rincon et al. (2019) RCT (8) Nstart=14 Nend=14 TPS=Subacute A vs 0 vs B	E: Custom exercise program + Usual care C: Usual Care C: 60 min/d, 5d/wk, for 4wks usual care Duration: E: 45 mins /d , 5d/wk, 4 wks + 15mins/d, 5d/wk, 4 wks ; C: 60 mins/d, 5d/wk, 4 wks	E vs C: Total Mini BESTest (+exp) Anticipatory postural adjustments (+exp) Postural responses (-) Sensory orientation (+exp) Balance during gait (+exp)
Askim et al. (2018) RCT (6) Nstart=380 Nend=329 TPS=Subacute A vs 0	E: Individualized Regular Coaching (on physical activity and exercise) + Standard Physiotherapy C: Standard Physiotherapy Duration: 45min/wk standard physiotherapy; 1d/mo coaching to schedule 45-60min/wk exercise & 30min/d, 7d/wk physical activity as intervention, for 18mo	E vs C: Motor Assessment Scale (-) Barthel Index (-) Modified Rankin Scale (-) Berg Balance scale-item 14 (-) Timed Up and Go Test (+con) Gait Speed (-) 6-minute walk test (-)

		Stroke Impact Scale (-) MMSE (-) Trailmaking A and B (-) Hospital Anxiety and Depression Scale (-) EQ-5D-5L (-) Fatigue Severity Scale (-) Caregiver Strain Index (-)
Sackley et al. (2015) RCT (8) Nstart=1042 Nend=908 TPS=Chronic A + B vs 0 Also in Table 24 (Home-Based and Caregiver-Mediated Exercise Programs)	E: Custom Occupational therapy + Caregiver training workshop C: Usual care alone Duration: 3mo program, frequency and duration of visits depended on patient and therapist	E vs C: Barthel index (-) Rivermead Mobility index (-) Geriatric depression scale-15 (-) EuroQOL-5D-3L questionnaire (-)
Askim et al. (2010) RCT (7) Nstart=62 Nend=59 TPS=Acute A + B vs 0	E: Intensive Motor Training + Home Exercise + Standard Treatment C: Standard Treatment Duration: 30min, 2x/d, 5d/wk, 12wks, Standard Treatment & 30-50min IMT, 3d/wk for first 4wks, and 1d/wk for the next 8wks & 2x/d, 6d/wk Home Exercise	E vs C: Berg Balance Scale (-) Barthel Index (-) Motor Assessment Scale (-) Step Test (-) 5-meter Walk Test (-) Stroke Impact Scale Recovery (-) Mobility (-)
Allen et al. (2009) RCT (7) Nstart=380 Nend=319 TPS=Subacute A vs B	E: Individualized post-discharge care plan (Home visits, Education, Medication, Social Support, Regular telephone assessment) C: Usual post-discharge Care Duration: Total of 6-mo protocol for both groups. 1x/wk, 4wks, then 1x/mo for 5mo periodic calls.	E vs C: NIHSS (-) Timed Up and Go Test (-) Physical Performance Test (-) Stroke-specific QOL scale (-) Risk Management Outcomes SBP (-) DBP (-) HBA1c(-) Fall rate (-) Incontinency (-) Center for Epidemiological Studies of Depression (-) medication appropriateness (-) Stroke Knowledge and Lifestyle Modification (+exp)
Werner et al. (2002a) RCT (7) Nstart=28 Nend=28 TPS=Subacute A + B + C vs A + B Also in Table 9 (Treadmill Training)	E: Baseline conventional therapy + Treadmill training with partial BWS + Individual physical therapy C: Baseline conventional therapy + Treadmill training with partial BWS Duration: 3wks Baseline conventional therapy, 30min/d, 5d/wk, for 3wks BWS-treadmill, 40min/d, 5d/wk, for 3wks Individual physical therapy	E vs C: Functional Ambulation Category (+exp) Rivermead Motor Assessment (-) Gait Velocity (-)
Aerobic and Resistance Training vs Aerobic Training		
Marzolini et al. (2018) RCT (6) Nstart=73 Nend=68	E: Aerobic training (over ground walking) + Resistance training C: Aerobic Training Duration: 20-60mins/d, 5d/wk for 24wks	E vs C: 6 minute walking distance (-) stair climb (-) sit-to-stand (-)

TPS=Chronic A + B vs A Also in Table 21 (Strength and Resistance Training)		cardiopulmonary assessment (-) resting heart rate (-) resting systolic BP (-) resting diastolic BP (-) VO2 peak (-) Peak RER (-) VO2 VT (+exp) Body composition Body mass index (-) Total body lean mass (+exp) Trunk (+exp) Appendicular Nonaffected-side limbs Affected-side limbs (+exp) Total body percentage fat (-) Trunk (-) Appendicular (-) Nonaffected-side limbs (-) Affected-side limbs (-) Muscular strength Elbow flexion, affected side (+exp) elbow flexion nonaffected side (+exp) knee extension, affected side knee extension nonaffected side (+exp) Dietary Analysis (-) kilocalories (-) protein (-)
Aerobic and Resistance Training vs Conventional Care		
Rizvi et al. (2023) RCT (7) Nstart=32 Nend=32 TPS=Subacute A vs B Also in Table 21 (Strength and Resistance Training)	E: Individualized cardio rehabilitation (aerobic & resistance training) + Conventional stroke rehab C: Conventional Stroke Rehabilitation Duration: 30-45min/d aerobic exercise, 4d/wk, +2d/wk body resistance training, for 12 wks	E vs C: BBS (-) TUG (+exp) mean NN (+exp) RMSSD (+exp) LF/HR ratio (-) SDNN (-) pNN50 (-) LF power (-) HF power (-) VLF power (-) total power (-) normalized LF (-) normalized HF (-) resting HR (+exp) peak HR (+exp) SBP (-) DBP (-) VE peak (+exp) RR peak (-) PETCOT2 rest (-) PETCO2 peak (+exp) VE/CO2 slope (+exp) VE/O2 slope (+exp) RER (+exp)

		workload (-) RPE (-) exercise duration (no stat)
Lee et al. (2015d) RCT (7) Nstart=30 Nend=26 TPS=Chronic A + B vs 0 Also in Table 21 (Strength and Resistance Training)	E: Aerobic Training (fast walking and walking up-stairs) + Resistance Training C: Conventional care Duration: 60min/d, 3d/wk, 16wks	E vs C: BP peripheral systolic/diastolic blood pressure (-) central systolic blood pressure (-) central diastolic blood pressure (+exp) augmentation index (+exp) Pulse wave velocity (+exp) 6-min walk test (+exp) 10-m walk test (+exp) Timed Up-and-Go Test (-) grip strength (+exp) flexibility (+exp) Functional Reach test (-) 30-sec chair stand test (+exp) chair sit and reach (+exp)
Closed Chain Exercise vs Open Chain Exercise or Standard Rehabilitation		
Krawczyk et al. (2014) RCT (4) Nstart=51 Nend=51 TPS=Subacute A vs 0	E: Closed chain rehabilitation program C: Standard rehabilitation program Duration: 120 min/d, for 12wks	E vs C: Berg-Balance Scale (-) Rivermead Motor Assessment-Trunk and LE (-) Fugl-Meyer Assessment-LE (-) Gait speed (-) Cadence (-) Stance phase (-) Step length (-) Step width (-) Hip range of motion (-) Range of pelvic tilt (-) Gillette Gait Index (-) Knee range of motion (-)
Lee et al. (2013f) RCT (3) Nstart=33 Nend=33 TPS=Chronic A1 vs A2 vs 0	E1: Closed Chain Kinetic exercise E2: Open Chain Kinetic exercise C: No Treatment Duration: 5d/wk, for 6wks	E1 v C: Muscle activity (+exp) Sway velocity (+exp) E2 v C: Muscle activity Rectus femoris (+exp) Biceps femoris (+exp) Gastrocnemius (-) Tibialis anterior (-) Sway velocity (-) E1 v E2: Muscle activity Rectus femoris (-) Biceps femoris (-) Gastrocnemius (+exp1) Tibialis anterior (+exp1) Sway velocity (+exp1)

Sling Exercise Therapy vs Conventional Therapy		
Wang et al. (2022a) RCT (4) Nstart=100 Nend=100 TPS=Subacute A vs B vs A + B vs 0	E1: Muscle energy technique + conventional therapy E2: Neurac + conventional therapy E3: Muscle energy technique + Neurac + conventional therapy C: Conventional therapy Duration: E: 4wks; C:40 mins/d, 5d/wk, 4wks	E1/E2/E3 vs C: Barthel Index (+exp1/2/3) VAS-pain (+exp1/2/3) BBS (+exp3) Tinetti score (+exp3) FMA (+exp1/2/3) WHO Quality of Life Measurements Short Form (+exp1/2/3) E1/E2 vs E3: BBS (+exp3) Tinetti scale (+exp3) Barthel Index (+exp3) VAS-pain (+exp3) FMA (+exp3) WHO Quality of Life Measurements Short Form (+exp3)
Liu et al. Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Body Weight Shift Technique may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	1	Krishna et al. 2018
1b	Self-regulation Rehabilitation may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	1	Liu et al. 2014
1a	Early Rehabilitation Programs may produce greater improvements in motor recovery than Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke.	11	Xu 2022; Ning et al. 2022; Liu et al. 2021b; Wang et al. 2022b; Yu et al. 2020b; Wu et al. 2020a; Pan 2018; Yelnik et al. 2017; Bai et al. 2012; Fang et al. 2003; Wade et al. 1992

1b	Early Conventional therapy (after 24-48 hours) may produce greater improvements in motor recovery than Late Conventional therapy (72-96 hours post stroke).	1	Wang et al. 2022b
2	Physical Therapy may not have a difference in efficacy when compared to No Treatment for improving motor recovery.	1	Werner et al. 1996
1a	Custom Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	3	Xia et al. 2020; Allen et al. 2009; Werner et al. 2002a
2	Closed Chain Exercise may not have a difference in efficacy when compared to Open Chain Exercise or Rehabilitation for improving motor recovery.	1	Krawczyk et al. 2014
1a	There is conflicting evidence about the effect of Sling Exercise Therapy when compared to Conventional Therapy for improving motor recovery.	2	Liu et al. 2020; Lou et al. 2019
2	Muscle energy technique with conventional therapy may result in lesser improvements in motor recovery when compared to Neurac with conventional therapy or Muscle energy technique, Neurac and conventional therapy.	1	Wang et al. 2022a
1b	Higher Intensity Training may produce greater improvements in motor recovery than Lower Intensity Training or Conventional Care.	2	Chen et al. 2024a; Sivenius et al. 1985
1b	Low-to-Moderate Intensity Continuous Training may not have a difference in efficacy when compared to Moderate Intensity Interval Training for improving motor recovery.	1	Chen et al. 2024a
1b	Low-to-Moderate Intensity Continuous Training may not have a difference in efficacy when compared to Reduced-Exertion High-Intensity Interval Training for improving motor recovery.	1	Chen et al. 2024a
1b	Low-to-Moderate Intensity Continuous Training or Moderate Intensity Interval Training may not have a difference in efficacy when compared to Conventional rehab for improving motor recovery.	1	Chen et al. 2024a
1b	Moderate Intensity Interval Training may not have a difference in efficacy when compared to Reduced-Exertion High-Intensity Interval Training for improving motor recovery.	1	Chen et al. 2024a
1b	Reduced-Exertion High-Intensity Interval Training may produce greater improvements in motor recovery than Conventional rehab.	1	Chen et al. 2024a
1b	Increased Duration of Exercise may not have a difference in efficacy when compared to Conventional Care/Exercise for improving motor recovery.	1	Hesse et al. 2011
1b	Community-based Exercise Program may produce greater improvements in motor recovery than Other Care.	1	Nindorera et al. 2023
1b	There is conflicting evidence about the effect of Motivational Interviewing with Occupational Therapy when compared to Occupational Therapy Alone for improving motor recovery.	1	Gholipour et al. 2024

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Agility Exercise may produce greater improvements in biomechanical gait measures than Stretching.	1	Marigold et al. 2005
2	Closed Chain Exercise may not have a difference in efficacy when compared to Open Chain Exercise or Rehabilitation for improving biomechanical gait measures.	1	Krawczyk et al. 2014
1b	Sling Exercise Therapy may produce greater improvements in biomechanical gait measures than Conventional Therapy.	1	Lou et al. 2019

2	Repetitive weight bearing exercises repeated 40 times may produce greater improvements in biomechanical gait measures than Repetitive weight bearing exercises repeated 20 times.	1	Agarwal et al. 2008
1b	There is conflicting evidence about the effect of Higher Intensity Training when compared to Lower Intensity Training or Conventional Care for improving biomechanical gait measures.	1	Hornby et al. 2016
1b	There is conflicting evidence about the effect of High-Intensity Training with Acute Intermittent Hypoxia when compared to High-Intensity Training Alone for improving biomechanical gait measures.	1	Hornby et al. 2024
1b	There is conflicting evidence about the effect of High-intensity variable stepping training or High-intensity forward stepping training when compared to Low-intensity variable stepping training for improving biomechanical gait measures.	1	Hornby et al. 2019

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Body Weight Shift Technique may produce greater improvements in biomechanical balance measures than Conventional Therapy.	1	Krishna et al. 2018
1b	Specific PT protocol (Techniques aimed to strengthen sensitivity, movement dissociation and balance. Were added based on patients functional level) may not have a difference in efficacy when compared to Conventional PT protocol for improving biomechanical balance measures.	1	Sánchez-Sánchez et al. 2018
1b	Cross-training Physiotherapy may not have a difference in efficacy when compared to Conventional Physiotherapy for improving biomechanical balance measures.	1	Park et al. 2021b

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Higher Intensity Training may not have a difference in efficacy when compared to Lower Intensity Training or Conventional Care for improving muscle strength.	1	Marzolini et al. 2023
1a	Increased Duration of Exercise may not have a difference in efficacy when compared to Conventional Care/Exercise for improving muscle strength.	2	Klassen et al. 2020; Wellwood et al. 2004
1b	There is conflicting evidence about the effect of Community-based Physical Activity when compared to No Intervention for improving muscle strength.	1	Kang et al. 2023
1b	Community-based Exercise Program may not have a difference in efficacy when compared to Other Care for improving muscle strength.	1	Olney et al. 2006
1b	Community-based Exercise Program may not have a difference in efficacy when compared to Upper Extremity Exercise Program for improving muscle strength.	1	Dean et al. 2012

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Physical Therapy may produce greater improvements in spasticity than No Treatment.	1	Hoseinabadi et al. 2013
1b	Increased Duration of Exercise may not have a difference in efficacy when compared to Conventional Care/Exercise for improving spasticity.	1	Hesse et al. 2011

1b	Community-based Exercise Program may not have a difference in efficacy when compared to Other Care for improving spasticity.	1	Harrington et al. 2010

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Range of Motion exercise program by themselves may not have a difference in efficacy when compared to Range of Motion exercise program with physical help for improving range of motion.	1	Tseng et al. 2007
1b	Aerobic and Resistance Training may not have a difference in efficacy when compared to Aerobic Training for improving range of motion.	1	Marzolini et al. 2018
2	Closed Chain Exercise may not have a difference in efficacy when compared to Open Chain Exercise or Rehabilitation for improving range of motion.	1	Krawczyk et al. 2014
1b	Community-based Physical Activity may produce greater improvements in range of motion than No Intervention.	1	Kang et al. 2023

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Neurorestoration Protocol Physiotherapy may not have a difference in efficacy when compared to Conventional Physiotherapy for improving neurophysiological measures.	1	Rahayu et al. 2020
1b	Agility Exercise may not have a difference in efficacy when compared to Stretching for improving neurophysiological measures.	1	Marigold et al. 2005
1b	Aerobic and Resistance Training may not have a difference in efficacy when compared to Aerobic Training for improving neurophysiological measures.	1	Marzolini et al. 2018
2	Closed Chain Exercise may produce greater improvements in neurophysiological measures than Open Chain Exercise or Rehabilitation.	1	Lee et al. 2013f
2	Higher Intensity Training may produce greater improvements in neurophysiological measures than Lower Intensity Training or Conventional Care.	1	Boyne et al. 2019

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Physio equipment may not have a difference in efficacy when compared to Conventional Therapy for improving aerobic measures.	1	Huang et al. 2022a
1b	Aerobic and Resistance Training may not have a difference in efficacy when compared to Aerobic Training for improving aerobic measures.	1	Marzolini et al. 2018
1a	Aerobic and Resistance Training may not have a difference in efficacy when compared to Conventional Care for improving aerobic measures.	2	Rizvi et al. 2023; Lee et al. 2015d
1a	Higher Intensity Training may not have a difference in efficacy when compared to Lower Intensity Training or Conventional Care for improving aerobic measures.	4	Moncion et al. 2024; Marzolini et al. 2023; Reynolds et al. 2021; Boyne et al. 2016
1b	Community-based Physical Activity may produce greater improvements in aerobic measures than No Intervention.	1	Kang et al. 2023

1b	Community-based Exercise Program may not have a difference in efficacy when compared to Other Care for improving aerobic measures.	1	Olney et al. 2006
1b	There is conflicting evidence about the effect of Community-based Exercise Program when compared to Upper Extremity Exercise Program for improving aerobic measures.	1	Pang et al. 2005
2	Skating Exercise may not have a difference in efficacy when compared to Treadmill Training for improving aerobic measures.	1	Soh et al. 2020
1b	High-Intensity Training with Acute Intermittent Hypoxia may not have a difference in efficacy when compared to High-Intensity Training Alone for improving aerobic measures.	1	Hornby et al. 2024
1b	Aerobic Exercise with Task-Specific Training may produce greater improvements in aerobic measures than Task-Specific Training Alone.	1	Linder et al. 2024
1b	High-intensity variable stepping training or High-intensity forward stepping training may not have a difference in efficacy when compared to Low-intensity variable stepping training for improving aerobic measures.	1	Hornby et al. 2019

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Custom Exercise Programs may produce greater improvements in sensory and proprioceptive function than Conventional Therapy.	1	Medina-Rincon et al. 2019

PAIN			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Range of Motion exercise program by themselves may not have a difference in efficacy when compared to Range of Motion exercise program with physical help for improving pain.	1	Tseng et al. 2007
1b	Range of Motion exercise program by themselves or Range of Motion exercise program with physical help may produce greater improvements in pain than Usual care.	1	Tseng et al. 2007
1b	Sling Exercise Therapy may produce greater improvements in pain than Conventional Therapy.	1	Liu et al. 2020
2	Muscle energy technique with conventional therapy may result in lesser improvements in pain when compared to Neurac with conventional therapy or Muscle energy technique, Neurac and conventional therapy.	1	Wang et al. 2022a
2	Muscle energy technique with conventional therapy or Neurac with conventional therapy or Muscle energy technique with Neurac with conventional therapy may produce greater improvements in pain than Conventional therapy.	1	Wang et al. 2022a
1b	Cognitive therapy with graded activity training may not have a difference in efficacy when compared to Cognitive therapy for improving pain.	1	Zedlitz et al. 2012

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Neurorestoration Protocol Physiotherapy may produce greater improvements in activities of daily living than Conventional Physiotherapy.	1	Rahayu et al. 2020
2	Leisure-time Physical Activity may not have a difference in efficacy when compared to Nonleisure-time Physical Activity for improving activities of daily living.	1	Ashizawa et al. 2021
1b	There is conflicting evidence about the effect of Self-regulation Rehabilitation when compared to Conventional Therapy for improving activities of daily living.	1	Liu et al. 2014
1b	Range of Motion exercise program by themselves may not have a difference in efficacy when compared to Range of Motion exercise program with physical help for improving activities of daily living.	1	Tseng et al. 2007
1a	There is conflicting evidence about the effect of Early Rehabilitation Programs when compared to Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke for improving activities of daily living.	16	Garcia-Perez et al. 2024; Xu 2022; Ning et al. 2022; Wang et al. 2022b; Liu et al. 2021b; Yen et al. 2020; Yu et al. 2020b; Wu et al. 2020a; Rahayu et al. 2019; Pan 2018; Langhorne et al. 2017; Yelnik et al. 2017; Bernhardt et al. 2015; Bai et al. 2012; Fang et al. 2003; Wade et al. 1992
1b	Early Conventional therapy (after 24-48 hours) may produce greater improvements in activities of daily living than Late Conventional therapy (72-96 hours post stroke).	1	Wang et al. 2022b
2	Physical Therapy may produce greater improvements in activities of daily living than No Treatment.	2	Hoseinabadi et al. 2013; Werner et al. 1996
1b	Occupational Therapy may produce greater improvements in activities of daily living than No Treatment.	1	Logan et al. 2004
1a	Custom Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	5	Swank et al. 2020; Xia et al. 2020; Askim et al. 2018; Sackley et al. 2015; Askim et al. 2010
1a	There is conflicting evidence about the effect of Sling Exercise Therapy when compared to Conventional Therapy for improving activities of daily living.	2	Liu et al. 2020; Lou et al. 2019
2	Muscle energy technique with conventional therapy may result in lesser improvements in activities of daily living when compared to Neurac with conventional therapy or Muscle energy technique, Neurac and conventional therapy.	1	Wang et al. 2022a
1b	Aerobic Exercise with Cognitive Training may not have a difference in efficacy when compared to Nonaerobic Exercise with Unstructured Mental Activities or Sham for improving activities of daily living.	1	Yeh et al. 2019
1b	High-intensity Functional Exercise Program may not have a difference in efficacy when compared to Education for improving activities of daily living.	1	Holmgren et al. 2010
1a	Higher Intensity Training may not have a difference in efficacy when compared to Lower Intensity Training or Conventional Care for improving activities of daily living.	4	Chen et al. 2024a; Gjellesvik et al. 2021; Langhammer et al. 2008; Sivenius et al. 1985

1b	Low-to-Moderate Intensity Continuous Training may not have a difference in efficacy when compared to Moderate Intensity Interval Training for improving activities of daily living.	1	Chen et al. 2024a
1b	Low-to-Moderate Intensity Continuous Training may result in lesser improvements in activities of daily living when compared to Reduced-Exertion High-Intensity Interval Training.	1	Chen et al. 2024a
1b	Moderate Intensity Interval Training may result in lesser improvements in activities of daily living when compared to Reduced-Exertion High-Intensity Interval Training.	1	Chen et al. 2024a
1b	Low-to-Moderate Intensity Continuous Training or Moderate Intensity Interval Training may not have a difference in efficacy when compared to Conventional rehab for improving activities of daily living.	1	Chen et al. 2024a
1b	Reduced-Exertion High-Intensity Interval Training may produce greater improvements in activities of daily living than Conventional rehab.	1	Chen et al. 2024a
1a	Increased Duration of Exercise may not have a difference in efficacy when compared to Conventional Care/Exercise for improving activities of daily living.	2	Hesse et al. 2011; Wellwood et al. 2004
1a	Community-based Physical Activity may not have a difference in efficacy when compared to No Intervention for improving activities of daily living.	2	Aravind et al. 2022; Green et al. 2002
1a	Community-based Exercise Program may not have a difference in efficacy when compared to Other Care for improving activities of daily living.	2	Harrington et al. 2010; Olney et al. 2006
1a	Community-based Exercise Program may produce greater improvements in activities of daily living than Upper Extremity Exercise Program.	2	Dean et al. 2012; Pang et al. 2005
1b	Non-Paretic Side Training may produce greater improvements in activities of daily living than Conventional Therapy.	1	Pandian et al. 2014
1b	Falls Prevention Program may not have a difference in efficacy when compared to Usual Care for improving activities of daily living.	1	Batchelor et al. 2012
1b	Motivational Interviewing with Occupational Therapy may produce greater improvements in activities of daily living than Occupational Therapy Alone.	1	Gholipour et al. 2024
1b	Team Care may not have a difference in efficacy when compared to conventional care for improving activities of daily living.	1	Wood-Dauphinee et al. 1984

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Body Weight Shift Technique may produce greater improvements in gait speed than Conventional Therapy.	1	Krishna et al. 2018
2	Physical Therapy may not have a difference in efficacy when compared to No Treatment for improving gait speed.	1	Werner et al. 1996
1a	Custom Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy for improving gait speed.	3	Askim et al. 2018; Askim et al. 2010; Werner et al. 2002a
1b	Aerobic and Resistance Training may produce greater improvements in gait speed than Conventional Care.	1	Lee et al. 2015d

1b	High-intensity Functional Exercise Program may produce greater improvements in falls and fear of falling than Education.	1	Holmgren et al. 2010
1b	Higher Intensity Training may not have a difference in efficacy when compared to Lower Intensity Training or Conventional Care for improving falls and fear of falling.	1	Hornby et al. 2016
1b	High-intensity variable stepping training or High-intensity forward stepping training may not have a difference in efficacy when compared to Low-intensity variable stepping training for improving falls and fear of falling.	1	Hornby et al. 2019
1b	Community-based Physical Activity may not have a difference in efficacy when compared to No Intervention for improving falls and fear of falling.	1	Green et al. 2002
1b	Community-based Exercise Program may not have a difference in efficacy when compared to Upper Extremity Exercise Program for improving falls and fear of falling.	1	Dean et al. 2012
1b	Falls Prevention Program may not have a difference in efficacy when compared to Usual Care for improving falls and fear of falling.	1	Batchelor et al. 2012
1b	High-Intensity Training with Acute Intermittent Hypoxia may not have a difference in efficacy when compared to High-Intensity Training Alone for improving falls and fear of falling.	1	Hornby et al. 2024

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Agility Exercise may not have a difference in efficacy when compared to Stretching for improving quality of life.	1	Marigold et al. 2005
1a	Early Rehabilitation Programs may not have a difference in efficacy when compared to Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke for improving quality of life.	2	Garcia-Perez et al. 2024; Yelnik et al. 2017
1b	Occupational Therapy may not have a difference in efficacy when compared to No Treatment for improving quality of life.	1	Logan et al. 2004
1a	Custom Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy for improving quality of life.	4	Swank et al. 2020; Askim et al. 2018; Sackley et al. 2015; Askim et al. 2010
2	Muscle energy technique with conventional therapy may result in lesser improvements in quality of life when compared to Neurac with conventional therapy or Muscle energy technique, Neurac and conventional therapy.	1	Wang et al. 2022a
1b	Aerobic Exercise with Cognitive Training may not have a difference in efficacy when compared to Nonaerobic Exercise with Unstructured Mental Activities or Sham for improving quality of life.	2	Koch et al. 2020; Yeh et al. 2019
1a	Higher Intensity Training may not have a difference in efficacy when compared to Lower Intensity Training or Conventional Care for improving quality of life.	5	Marzolini et al. 2023; Reynolds et al. 2021; Gjellesvik et al. 2021;

			Hornby et al. 2016; Langhammer et al. 2008
1a	Community-based Physical Activity may not have a difference in efficacy when compared to No Intervention for improving quality of life.	2	Marsden et al. 2010; Green et al. 2002
1a	Community-based Exercise Program may not have a difference in efficacy when compared to Other Care for improving quality of life.	4	Nindorera et al. 2023; Stuart et al. 2019; Harrington et al. 2010; Olney et al. 2006
2	Skating Exercise may produce greater improvements in quality of life than Treadmill Training.	1	Soh et al. 2020
1b	High-Intensity Training with Acute Intermittent Hypoxia may not have a difference in efficacy when compared to High-Intensity Training Alone for improving quality of life.	1	Hornby et al. 2024
1b	Motivational Interviewing with Occupational Therapy may not have a difference in efficacy when compared to Occupational Therapy Alone for improving quality of life.	1	Gholipour et al. 2024
1b	If-Then goal setting for exercise may not have a difference in efficacy when compared to Goal setting for improving quality of life.	1	Kersten et al. 2015
1b	Cognitive therapy with graded activity training may produce greater improvements in quality of life than Cognitive therapy.	1	Zedlitz et al. 2012

Other Associated Outcome Measures

MOOD			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Early Rehabilitation Programs may not have a difference in efficacy when compared to Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke for improving mood.	2	Garcia-Perez et al. 2024; Wade et al. 1992
1b	Custom Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy for improving mood.	1	Askim et al. 2018
1a	Higher Intensity Training may not have a difference in efficacy when compared to Lower Intensity Training or Conventional Care for improving mood.	2	Reynolds et al. 2021; Gjellesvik et al. 2021
1a	Increased Duration of Exercise may not have a difference in efficacy when compared to Conventional Care/Exercise for improving mood.	2	Klassen et al. 2020; Partridge et al. 2000
1b	Community-based Physical Activity may not have a difference in efficacy when compared to No Intervention for improving mood.	1	Green et al. 2002
1a	Community-based Exercise Program may not have a difference in efficacy when compared to Other Care for improving mood.	2	Nindorera et al. 2023; Harrington et al. 2010
1b	Motivational Interviewing with Occupational Therapy may not have a difference in efficacy when compared to Occupational Therapy Alone for improving mood.	1	Gholipour et al. 2024
1b	Cognitive therapy with graded activity training may not have a difference in efficacy when compared to Cognitive therapy for improving mood.	1	Zedlitz et al. 2012

FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Custom Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy for improving fatigue and sleep.	1	Askim et al. 2018

1b	Higher Intensity Training may not have a difference in efficacy when compared to Lower Intensity Training or Conventional Care for improving fatigue and sleep.	1	Langhammer et al. 2008
1b	Cognitive therapy with graded activity training may not have a difference in efficacy when compared to Cognitive therapy for improving fatigue and sleep.	1	Zedlitz et al. 2012

COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Early Rehabilitation Programs when compared to Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke for improving cognition.	2	Garcia-Perez et al. 2024; Fang et al. 2003
1b	Custom Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy for improving cognition.	1	Askim et al. 2018
1b	Aerobic Exercise with Cognitive Training may not have a difference in efficacy when compared to Nonaerobic Exercise with Unstructured Mental Activities or Sham for improving cognition.	2	Koch et al. 2020; Yeh et al. 2019
1a	Higher Intensity Training may not have a difference in efficacy when compared to Lower Intensity Training or Conventional Care for improving cognition.	2	Marzolini et al. 2023; Gjellesvik et al. 2021

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Self-regulation Rehabilitation may not have a difference in efficacy when compared to Conventional Therapy for improving upper extremity function.	1	Liu et al. 2014
1b	Range of Motion exercise program by themselves may result in lesser improvements in upper extremity function when compared to Range of Motion exercise program with physical help.	1	Tseng et al. 2007
1b	Agility Exercise may not have a difference in efficacy when compared to Stretching for improving upper extremity function.	1	Marigold et al. 2005
1a	Early Rehabilitation Programs may not have a difference in efficacy when compared to Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke for improving upper extremity function.	2	Garcia-Perez et al. 2024; Wang et al. 2022b
1b	Early Conventional therapy (after 24-48 hours) may not have a difference in efficacy when compared to Late Conventional therapy (72-96 hours post stroke) for improving upper extremity function.	1	Wang et al. 2022b
1b	Aerobic and Resistance Training may produce greater improvements in upper extremity function than Aerobic Training.	1	Marzolini et al. 2018
1b	Aerobic and Resistance Training may produce greater improvements in upper extremity function than Conventional Care.	1	Lee et al. 2015d
2	There is conflicting evidence about the effect of Closed Chain Exercise when compared to Open Chain Exercise or Rehabilitation for improving upper extremity function.	1	Lee et al. 2013f
1b	Sling Exercise Therapy may produce greater improvements in upper extremity function than Conventional Therapy.	1	Liu et al. 2020
2	Aerobic Exercise with Cognitive Training may not have a difference in efficacy when compared to Nonaerobic Exercise with Unstructured Mental Activities or Sham for improving upper extremity function.	1	Koch et al. 2020

1b	Aerobic Exercise with Task-Specific Training may not have a difference in efficacy when compared to Task-Specific Training Alone for improving upper extremity function.	1	Linder et al. 2024

Key Points

- Body Weight Shift Technique may be beneficial for improving biomechanical balance measures, gait speed, and balance, but not motor recovery, after stroke when compared to Conventional Therapy.
- Neurorestoration Protocol Physiotherapy may be beneficial for improving activities of daily living and balance, but not neurophysiological measures, after stroke when compared to Conventional Physiotherapy.
- Leisure-time Physical Activity may not be beneficial for improving activities of daily living, gait endurance, and functional mobility after stroke when compared to Nonleisure-time Physical Activity.
- Self-regulation Rehabilitation may not be beneficial for improving motor recovery after stroke when compared to Conventional Therapy; the literature is mixed regarding activities of daily living.
- Range of Motion exercise program by themselves may not be beneficial for improving range of motion, pain, and activities of daily living after stroke when compared to Range of Motion exercise program with physical help.
- Agility Exercise may be beneficial for improving biomechanical gait measures, but not neurophysiological measures, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Stretching.
- Physio equipment may be beneficial for improving balance, but not aerobic measures, after stroke when compared to Conventional Therapy.
- Early Rehabilitation Programs may be beneficial for improving motor recovery, but not functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke; the literature is mixed regarding activities of daily living.
- Early Conventional therapy (after 24-48 hours) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Late Conventional therapy (72-96 hours post stroke).
- Physical Therapy may be beneficial for improving spasticity, activities of daily living, and balance, but not motor recovery, gait speed, and functional mobility, after stroke when compared to No Treatment.
- Occupational Therapy may be beneficial for improving activities of daily living, but not quality of life, after stroke when compared to No Treatment.
- Custom Exercise Programs may be beneficial for improving sensory and proprioceptive function, but not motor recovery, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy.
- Aerobic and Resistance Training may not be beneficial for improving range of motion, neurophysiological measures, aerobic measures, gait endurance, and functional mobility after stroke when compared to Aerobic Training.
- Aerobic and Resistance Training may be beneficial for improving gait speed and gait endurance, but not aerobic measures, functional mobility, and balance, after stroke when compared to Conventional Care.
- Closed Chain Exercise may be beneficial for improving neurophysiological measures, but not motor recovery, biomechanical gait measures, range of motion, functional mobility, and balance, after stroke when compared to Open Chain Exercise or Rehabilitation; the literature is mixed regarding gait speed.
- Sling Exercise Therapy may be beneficial for improving biomechanical gait measures, pain, gait speed, functional mobility, and balance after stroke when compared to Conventional Therapy; the literature is mixed regarding motor recovery and activities of daily living.
- Muscle energy technique with conventional therapy may result in lesser improvements in motor recovery, pain, activities of daily living, functional mobility, balance, and quality of life when compared to Neurac with conventional therapy or Muscle energy technique, Neurac and conventional therapy.
- Aerobic Exercise with Cognitive Training may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Nonaerobic Exercise with Unstructured Mental Activities or Sham; the literature is mixed regarding gait endurance.

- Virtual Reality Exercise Program may not be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to Customized Physiotherapy or Conventional Physiotherapy.
- High-intensity Functional Exercise Program may be beneficial for improving falls and fear of falling, but not activities of daily living and balance, after stroke when compared to Education.
- Repetitive weight bearing exercises repeated 40 times may be beneficial for improving biomechanical gait measures after stroke when compared to Repetitive weight bearing exercises repeated 20 times.
- Higher Intensity Training may be beneficial for improving motor recovery and neurophysiological measures, but not muscle strength, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Lower Intensity Training or Conventional Care; the literature is mixed regarding biomechanical gait measures.
- Low-to-Moderate Intensity Continuous Training may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Moderate Intensity Interval Training.
- Low-to-Moderate Intensity Continuous Training may not be beneficial for improving motor recovery after stroke when compared to Reduced-Exertion High-Intensity Interval Training; Low-to-Moderate Intensity Continuous Training may result in lesser improvements in activities of daily living when compared to Reduced-Exertion High-Intensity Interval Training.
- Increased Duration of Exercise may not be beneficial for improving motor recovery, muscle strength, spasticity, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Conventional Care/Exercise.
- Community-based Physical Activity may be beneficial for improving range of motion, aerobic measures, and gait speed, but not activities of daily living, gait endurance, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to No Intervention; the literature is mixed regarding muscle strength.
- Community-based Exercise Program may be beneficial for improving motor recovery, but not muscle strength, spasticity, aerobic measures, activities of daily living, gait speed, functional mobility, balance, and quality of life, after stroke when compared to Other Care; the literature is mixed regarding gait endurance.
- Community-based Exercise Program may be beneficial for improving activities of daily living and gait endurance, but not muscle strength, functional mobility, balance, and falls and fear of falling, after stroke when compared to Upper Extremity Exercise Program; the literature is mixed regarding aerobic measures and gait speed.
- Non-Paretic Side Training may be beneficial for improving activities of daily living after stroke when compared to Conventional Therapy; the literature is mixed regarding balance.
- Falls Prevention Program may not be beneficial for improving activities of daily living, functional mobility, and falls and fear of falling after stroke when compared to Usual Care.
- Skating Exercise may be beneficial for improving functional mobility, balance, and quality of life, but not aerobic measures, after stroke when compared to Treadmill Training.
- High-Intensity Training with Acute Intermittent Hypoxia may be beneficial for improving gait speed, but not aerobic measures, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to High-Intensity Training Alone; the literature is mixed regarding biomechanical gait measures.
- Aerobic Exercise with Task-Specific Training may be beneficial for improving aerobic measures and gait endurance after stroke when compared to Task-Specific Training Alone.
- Motivational Interviewing with Occupational Therapy may be beneficial for improving activities of daily living, but not quality of life, after stroke when compared to Occupational Therapy Alone; the literature is mixed regarding motor recovery.
- Specific PT protocol (Techniques aimed to strengthen sensitivity, movement dissociation and balance. Were added based on patients functional level) may not be beneficial for improving biomechanical balance measures and balance after stroke when compared to Conventional PT protocol.
- If-Then goal setting for exercise may not be beneficial for improving gait speed, functional mobility, and quality of life after stroke when compared to Goal setting.

- Cognitive therapy with graded activity training may be beneficial for improving gait endurance and quality of life, but not pain, after stroke when compared to Cognitive therapy.
- Team Care may not be beneficial for improving activities of daily living after stroke when compared to conventional care.
- Cross-training Physiotherapy may not be beneficial for improving biomechanical balance measures, gait speed, and functional mobility after stroke when compared to Conventional Physiotherapy.
- Range of Motion exercise program by themselves may be beneficial for improving pain after stroke when compared to Usual care.
- Range of Motion exercise program with physical help may be beneficial for improving pain after stroke when compared to Usual care.
- Muscle energy technique with conventional therapy may be beneficial for improving pain after stroke when compared to Conventional therapy.
- Neurac with conventional therapy may be beneficial for improving pain after stroke when compared to Conventional therapy.
- Moderate Intensity Interval Training may not be beneficial for improving motor recovery after stroke when compared to Reduced-Exertion High-Intensity Interval Training; Moderate Intensity Interval Training may result in lesser improvements in activities of daily living when compared to Reduced-Exertion High-Intensity Interval Training.
- High-intensity forward stepping training may be beneficial for improving gait speed and gait endurance, but not aerobic measures, functional mobility, and falls and fear of falling, after stroke when compared to Low-intensity variable stepping training; the literature is mixed regarding biomechanical gait measures.
- High-intensity variable stepping training may be beneficial for improving gait speed and gait endurance, but not aerobic measures, functional mobility, and falls and fear of falling, after stroke when compared to Low-intensity variable stepping training; the literature is mixed regarding biomechanical gait measures.
- Muscle energy technique with Neurac with conventional therapy may be beneficial for improving pain after stroke when compared to Conventional therapy.
- Low-to-Moderate Intensity Continuous Training or Moderate Intensity Interval Training may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional rehab.
- Reduced-Exertion High-Intensity Interval Training may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional rehab.

Summary of Key Points: Physiotherapy and Exercise Programs

Intervention	Control(s)	Function domain(s)	Effect
Body Weight Shift Technique	Conventional Therapy	Biomechanical balance measures, gait speed, balance	+
Body Weight Shift Technique	Conventional Therapy	Motor recovery	–
Neurorestoration Protocol Physiotherapy	Conventional Physiotherapy	Activities of daily living, balance	+
Neurorestoration Protocol Physiotherapy	Conventional Physiotherapy	Neurophysiological measures	–
Leisure-time Physical Activity	Nonleisure-time Physical Activity	Activities of daily living, gait endurance, functional mobility	–
Self-regulation Rehabilitation	Conventional Therapy	Motor recovery	–
Self-regulation Rehabilitation	Conventional Therapy	Activities of daily living	=
Range of Motion exercise program by themselves	Range of Motion exercise program with physical help	Range of motion, pain, activities of daily living	–

Agility Exercise	Stretching	Biomechanical gait measures	+
Agility Exercise	Stretching	Neurophysiological measures, functional mobility, balance, falls and fear of falling, quality of life	–
Physio equipment	Conventional Therapy	Balance	+
Physio equipment	Conventional Therapy	Aerobic measures	–
Early Rehabilitation Programs	Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke	Motor recovery	+
Early Rehabilitation Programs	Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke	Functional mobility, balance, quality of life	–
Early Conventional therapy (after 24-48 hours)	Late Conventional therapy (72-96 hours post stroke)	Motor recovery, activities of daily living	+
Physical Therapy	No Treatment	Spasticity, activities of daily living, balance	+
Physical Therapy	No Treatment	Motor recovery, gait speed, functional mobility	–
Occupational Therapy	No Treatment	Activities of daily living	+
Occupational Therapy	No Treatment	Quality of life	–
Custom Exercise Programs	Conventional Therapy	Sensory and proprioceptive function	+
Custom Exercise Programs	Conventional Therapy	Motor recovery, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Aerobic and Resistance Training	Aerobic Training	Range of motion, neurophysiological measures, aerobic measures, gait endurance, functional mobility	–
Aerobic and Resistance Training	Conventional Care	Gait speed, gait endurance	+
Aerobic and Resistance Training	Conventional Care	Aerobic measures, functional mobility, balance	–
Closed Chain Exercise	Open Chain Exercise or Rehabilitation	Neurophysiological measures	+
Closed Chain Exercise	Open Chain Exercise or Rehabilitation	Motor recovery, biomechanical gait measures, range of motion, functional mobility, balance	–
Closed Chain Exercise	Open Chain Exercise or Rehabilitation	Gait speed	=
Sling Exercise Therapy	Conventional Therapy	Biomechanical gait measures, pain, gait speed, functional mobility, balance	+
Sling Exercise Therapy	Conventional Therapy	Motor recovery, activities of daily living	=
Muscle energy technique with conventional therapy	Neurac with conventional therapy or Muscle energy technique, Neurac and conventional therapy	Motor recovery, pain, activities of daily living, functional mobility, balance, quality of life	–

Aerobic Exercise with Cognitive Training	Nonaerobic Exercise with Unstructured Mental Activities or Sham	Activities of daily living, gait speed, functional mobility, quality of life	–
Aerobic Exercise with Cognitive Training	Nonaerobic Exercise with Unstructured Mental Activities or Sham	Gait endurance	=
Virtual Reality Exercise Program	Customized Physiotherapy or Conventional Physiotherapy	Gait speed, functional mobility, balance	–
High-intensity Functional Exercise Program	Education	Falls and fear of falling	+
High-intensity Functional Exercise Program	Education	Activities of daily living, balance	–
Repetitive weight bearing exercises repeated 40 times	Repetitive weight bearing exercises repeated 20 times	Biomechanical gait measures	+
Higher Intensity Training	Lower Intensity Training or Conventional Care	Motor recovery, neurophysiological measures	+
Higher Intensity Training	Lower Intensity Training or Conventional Care	Muscle strength, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Higher Intensity Training	Lower Intensity Training or Conventional Care	Biomechanical gait measures	=
Low-to-Moderate Intensity Continuous Training	Moderate Intensity Interval Training	Motor recovery, activities of daily living	–
Low-to-Moderate Intensity Continuous Training	Reduced-Exertion High-Intensity Interval Training	Motor recovery, activities of daily living	–
Low-to-Moderate Intensity Continuous Training	Reduced-Exertion High-Intensity Interval Training	Activities of daily living	–
Increased Duration of Exercise	Conventional Care/Exercise	Motor recovery, muscle strength, spasticity, activities of daily living, gait speed, functional mobility, balance	–
Community-based Physical Activity	No Intervention	Range of motion, aerobic measures, gait speed	+
Community-based Physical Activity	No Intervention	Activities of daily living, gait endurance, functional mobility, falls and fear of falling, quality of life	–
Community-based Physical Activity	No Intervention	Muscle strength	=
Community-based Exercise Program	Other Care	Motor recovery	+
Community-based Exercise Program	Other Care	Muscle strength, spasticity, aerobic measures, activities of daily living, gait speed, functional mobility, balance, quality of life	–
Community-based Exercise Program	Other Care	Gait endurance	=
Community-based Exercise Program	Upper Extremity Exercise Program	Activities of daily living, gait endurance	+
Community-based Exercise Program	Upper Extremity Exercise Program	Muscle strength, functional mobility, balance, falls and fear of falling	–

Community-based Exercise Program	Upper Extremity Exercise Program	Aerobic measures, gait speed	=
Non-Paretic Side Training	Conventional Therapy	Activities of daily living	+
Non-Paretic Side Training	Conventional Therapy	Balance	=
Falls Prevention Program	Usual Care	Activities of daily living, functional mobility, falls and fear of falling	−
Skating Exercise	Treadmill Training	Functional mobility, balance, quality of life	+
Skating Exercise	Treadmill Training	Aerobic measures	−
High-Intensity Training with Acute Intermittent Hypoxia	High-Intensity Training Alone	Gait speed	+
High-Intensity Training with Acute Intermittent Hypoxia	High-Intensity Training Alone	Aerobic measures, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	−
High-Intensity Training with Acute Intermittent Hypoxia	High-Intensity Training Alone	Biomechanical gait measures	=
Aerobic Exercise with Task-Specific Training	Task-Specific Training Alone	Aerobic measures, gait endurance	+
Motivational Interviewing with Occupational Therapy	Occupational Therapy Alone	Activities of daily living	+
Motivational Interviewing with Occupational Therapy	Occupational Therapy Alone	Quality of life	−
Motivational Interviewing with Occupational Therapy	Occupational Therapy Alone	Motor recovery	=
Specific PT protocol (Techniques aimed to strengthen sensitivity, movement dissociation and balance. Were added based on patients functional level)	Conventional PT protocol	Biomechanical balance measures, balance	−
If-Then goal setting for exercise	Goal setting	Gait speed, functional mobility, quality of life	−
Cognitive therapy with graded activity training	Cognitive therapy	Gait endurance, quality of life	+
Cognitive therapy with graded activity training	Cognitive therapy	Pain	−
Team Care	conventional care	Activities of daily living	−
Cross-training Physiotherapy	Conventional Physiotherapy	Biomechanical balance measures, gait speed, functional mobility	−
Early Rehabilitation Programs	Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke	Balance	−
Range of Motion exercise program by themselves	Usual care	Pain	+
Range of Motion exercise program with physical help	Usual care	Pain	+
Muscle energy technique with conventional therapy	Conventional therapy	Pain	+

Neurac with conventional therapy	Conventional therapy	Pain	+
Moderate Intensity Interval Training	Reduced-Exertion High-Intensity Interval Training	Motor recovery, activities of daily living	–
Low-to-Moderate Intensity Continuous Training or Moderate Intensity Interval Training	Conventional rehab	Motor recovery, activities of daily living	–
Early Rehabilitation Programs	Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke	Activities of daily living	=
High-intensity forward stepping training	Low-intensity variable stepping training	Biomechanical gait measures	=
High-intensity forward stepping training	Low-intensity variable stepping training	Aerobic measures, functional mobility, falls and fear of falling	–
High-intensity forward stepping training	Low-intensity variable stepping training	Gait speed, gait endurance	+
High-intensity variable stepping training	Low-intensity variable stepping training	Biomechanical gait measures	=
High-intensity variable stepping training	Low-intensity variable stepping training	Aerobic measures, functional mobility, falls and fear of falling	–
High-intensity variable stepping training	Low-intensity variable stepping training	Gait speed, gait endurance	+
Muscle energy technique with Neurac with conventional therapy	Conventional therapy	Pain	+
Reduced-Exertion High-Intensity Interval Training	Conventional rehab	Motor recovery, activities of daily living	+

Balance Training

Adapted from: https://www.flintrehab.com/regaining-balance-after-stroke/

Balance impairment is a common early symptom after stroke and is strongly associated with future recovery. Likewise, balance problems are the strongest predictors for future falls and related injuries (Lubetzky-Vilnai & Kartin, 2010). Multiple interventions have aimed to improve balance in multi-faceted approaches. Many balance-

focused rehabilitation strategies employ visual feedback to facilitate improvements in symmetrical weight bearing and posture. Recently, technological approaches have expanded the quantity and quality of real-time feedback on balance performance. Feedback driven interventions for balance training include bodyweight supported training, fixed, supportive and perturbation-based balance platforms and trunk training.

A total of 94 RCTs were found that evaluated balance training for lower extremity motor rehabilitation. Six RCTs compared Balance-Focused Exercise Programs with Conventional Rehabilitation (Rauf et al. 2024; Tan et al. 2023; Battesha et al. 2022; Puckree et al. 2014; Alptekin et al. 2008; Pollock et al. 2002). One RCT compared Task Specific Balance Training with Upper Limb Exercise (Pang et al. 2018). One RCT compared Balance Training with Posture Changes with Balance Training (Jiang et al. 2021). Three RCTs compared Wobble Board Training with Conventional Physiotherapy (Nagai et al. 2024; Madhuranga et al. 2019; Onigbinde et al. 2009). One RCT compared Balance-Focused Exercise Programs with At-home Exercises (Curuk & Aruin 2022). Four RCTs compared Balance Training Using SMART Balance Master with Conventional Rehabilitation (Rao et al. 2013; Chen et al. 2002; Geiger et al. 2001; Walker et al. 2000). Four RCTs compared Non-Supportive Balance Trainers with Feedback with Conventional Therapy or Balance Training (Komiya et al. 2021; Brunelli et al. 2020; Zhang et al. 2020; Maciaszek. 2018). Twelve RCTs compared Balance Training with Visual Biofeedback with Conventional Therapy or Balance Training (Aphiphaksakul et al. 2022; Noh et al. 2019; James et al. 2017; Ghomashchi 2016; Ordahan et al. 2015; Ko et al. 2015; De Nunzio et al. 2014; Lee et al. 2013e; Yoon et al. 2013; Varoqui et al. 2011; Yavuzer et al. 2006a; Sackley & Lincoln 1997). Three RCTs compared Standing Practice with Conventional Therapy (Inoue et al. 2021; Allison et al. 2007; Wong et al. 1997). Three RCTs compared Perturbation Balance Trainers with Feedback with Conventional Therapy or Balance Training (An et al. 2021; Jung et al. 2021; Thijs et al. 2021). Ten RCTs compared Perturbation Balance Trainers with Conventional Therapy or Balance Training (Lanza et al. 2024; Shen et al. 2023; Dusane & Bhatt 2022; Chayasit et al. 2022; Schinkel-Ivy et al. 2019; Handelzalts et al. 2019; Yadav et al. 2020; Mansfield et al. 2018; Yadav et al. 2018; Goljar et al. 2010). Five RCTs compared Balance Training with Visual Deprivation with Balance Training with Visual Cues (Jeong et al. 2024; Nam et al. 2022a; Narendra et al. 2013; Yelnik et al. 2008; Bonan et al. 2004). One RCT compared Balance Training with Kinesthetic Ability Training Device with Conventional Rehabilitation (Alptekin et al. 2008). One RCT compared Balance Training with Full Rest Periods with Balance Training with Short Rest Periods (Elsner et al. 2018). One RCT compared Balance Training with Muscle Vibration with Conventional Rehabilitation (Merkert et al. 2011). Five RCTs compared Balance Training with Biofeedback with Balance Training (Martino Cinnera et al. 2024; Kim et al. 2022e; Lupo et al. 2018; Hung et al. 2017; Eser et al. 2008). Six RCTs compared Vestibular Training with Conventional Therapy (Calisgan et al. 2024; Cui et al. 2024; Son et al. 2024; Zhao et al. 2022b; Ekvall Hansson et al. 2020; Tramontano et al. 2018). Three RCTs compared Robotic Balance Training with Conventional Therapy (Inoue et al. 2022b; De Luca et al. 2020; Kumar et al. 2020). One RCT compared Trampoline Balance Training with Stable Surface Balance Training (Miklitsch et al. 2013). One RCT compared Ankle-Foot orthosis + Balance Training Shoes with Ankle-Foot Orthosis + Regular Shoes (Farmani et al. 2016). One RCT compared Balance Training + TENS with Balance Training + Conventional Care (Jung et al. 2016). One RCT compared Balance Training with Shoe Lift with Balance Training (Sheikh & Hosseini 2021). Three RCTs compared Strength or Resistance Training with Balance Training with Conventional Therapy (Vahlberg et al. 2017a; Vahlberg et al. 2017b; Sekhar et al. 2013). One RCT compared Structured Balance Awareness with Health Awareness Program (Shaik et al. 2021). One RCT compared Balance Training with Fresnel Prism Glasses with Balance and Walking Training (Ha & Sung 2020). One RCT compared Sensory Balance Training with Robot-assisted Stair Climbing (Gandolfi et al. 2019). One RCT compared Sitting Balance Training with Sensory Input with Sitting Balance (Ibrahimi et al. 2010). One RCT compared External focus on Balance Board with Internal focus on Balance Board (Kal et al. 2019). One RCT compared Balance Training with No Training (Lisinski et al. 2012). Two RCTs compared Vestibular rehabilitation with Convectional treatment (Balci et al. 2013; Dai et al. 2013). One RCT compared Progressive Balance Training with Standard Balance Training (Memon et al. 2022). One RCT compared Perturbation Balance Training with Proprioceptive Neuromuscular Facilitation (Adhikari et al. 2024). One RCT compared Class-Based Body Awareness Training with Home-Based Body Awareness Training (Serrada et al. 2022). One RCT compared Visual Scanning Training with Task-Specific Activities with Task-Specific Activities Alone (Batool et al. 2022). One RCT compared Vestibular Training with Virtual Reality Training (Sana et al. 2023).

In addition, 39 RCTs in which balance training formed part of a combined or comparative intervention are cross-referenced at the end of Table 11; their primary listings appear in other tables.

The methodological details and results of all 94 RCTs are presented in Table 11.

Table 11. RCTs Evaluating Balance Training for Lower Extremity Motor Rehabilitation

Authors (Year)	Interventions	Outcome Measures

Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Duration: Session length, frequency per week for total number of weeks	Result (direction of effect)
Balance-Focused Exercise Programs vs Conventional Rehabilitation		
Rauf et al. (2024) RCT (5) Nstart=52 Nend=52 TPS=Chronic A vs 0	E: Postural and kinesthetic awareness + routine physical therapy C: Conventional rehab Duration: 60min/d, 5d/wk, 6 wks	E vs C: Berg Balance Scale (+exp) Static Plantar Pressure Evaluation (+exp)
Tan et al. (2023) RCT (7) Nstart=112 Nend=112 TPS=Subacute A + B vs B + C + D	E: Balance training + Auxiliary activity C: Auxiliary activity (mobility aid + stretching + sensory stimulation) Duration: 15min balance training + 5-6hr/d auxiliary activity, 7d/wk, 8wks	E vs C: BBA (+exp) TUG (+exp) FMA-LE (+exp) Morse fall scale (+exp) FAC (+exp) falls during hospitalization (-)
Battesha et al. (2022) RCT (5) Nstart=30 Nend=30 TPS=Chronic A vs 0	E: Conventional Physical Rehabilitation + Maze Control C: Conventional Physical Rehabilitation Duration: 60min (20min maze +40min CT)/d, 3d/wk, 8wks	E vs C: Sway Index open eyes-firm surface(+exp) closed eyes-firm surface (+exp) open eyes-foam surface (+exp) closed eyes-foam surface (+exp) Risk of Fall(+exp) Knee Proprioception 15 deg(-) 30 deg (-) 75 deg (+exp)
Puckree et al. (2014) RCT (5) Nstart=50 Nend=50 TPS=Chronic A vs 0	E: Outpatient community-based Balance and Stability focused rehabilitation C: Regular physiotherapy Duration: 30min/d, 1d/2wks, for 24wks	E vs C: Postural assessment scale for stroke patients (+exp) Berg balance scale (+exp)
Pollock et al. (2002) RCT (3) Nstart=28 Nend=16 TPS=Subacute A vs 0	E: Independent balance practice + conventional therapy C: Conventional therapy Duration: 5d/wk, 4wks	E vs C: Weight Distribution (-) Balance (-)
Task Specific Balance Training vs Upper Limb Exercise		
Pang et al. (2018) RCT (8) Nstart=84 Nend=78 TPS=Chronic A1 vs A2 vs B Also in Table 16 (Dual-Task Training)	E1: Dual-task balance/mobility E2: Single-task balance/mobility C: Upper limb exercise Duration: 60min/d, 3d/wk, for 8wks	E1 vs E2/C: Percent dual-task effect(%DTE) in walking time when forward walking+ verbal fluency (+exp1) when forward walking+ serial-3-subtractions (+exp1) when TUG+ verbal fluency (+exp1) when TUG + serial-3-subtractions (-) %DTE in correct response rate

		when forward walking+ verbal fluency (-) when forward walking+ serial-3-subtractions (-) when TUG+ verbal fluency (-) when TUG + serial-3-subtractions (-) Activities-specific Balance Confidence Scale (-) Frenchay Activities Index (-) Stroke-specific Quality of Life Scale (-) E2 vs C: DTE%-all tasks (-) DTE% in correct response rate-all tasks (-) Activities-specific Balance Confidence Scale (-) Frenchay Activities Index (-) Stroke-specific Quality of Life Scale (-)
Balance Training with Posture Changes vs Balance Training		
Jiang et al. (2021) RCT (9) Nstart=60 Nend=57 TPS=Chronic A + B vs C + B vs B	E1: Shoulder elevation posture change + balance training + Conventional training E2: Back posture change + balance training + Conventional training C: Conventional training + Balance training Duration: 30min/d, 5d/wk for 4wks	E1 vs C: EMG Test (+exp1) Fugl-Meyer assessment (+exp1) 10m Walk (+exp1) Barthel index (-) E2 vs C: EMG Test (+exp2) Fugl-Meyer assessment (-) 10m Walk (-) Barthel index (-) E1 vs E2: EMG Test (+exp1) Fugl-Meyer assessment (+exp1) 10m Walk (+exp1) Barthel index (-)
Wobble Board Training vs Conventional Physiotherapy		
Nagai et al. (2024) RCT (6) Nstart=43 Nend=42 TPS=Subacute A + B vs 0 Also in Table 13 (Orthotic Devices)	E: Unstable board intervention (using AIREX Balance-pad) under non-paralyzed lower leg + Knee ankle foot orthosis (KAFO) on paralyzed leg + Usual physical therapy C: Usual Physical Therapy Duration: 40min/d, for 3d	E vs C: angle of RR in paralyzed side tilt condition neck (-) trunk (+exp) paralyzed lower leg (-) non-paralyzed lower leg (-) angle of RR in non-paralyzed side tilt condition neck (-) trunk (+exp) paralyzed lower leg (-) non-paralyzed lower leg (-) Movement distance of COP of the RR paralyzed side tilted (+exp) non-paralyzed side tilted (+exp)
Madhuranga et al. (2019) RCT (6) Nstart=30 Nend=29 TPS=Chronic	E: Wobble board training + Conventional physiotherapy C: Conventional physiotherapy Duration: 50min/d, 2d/wk, for 6wks	E vs C: Four-Square Step Test (+exp) Berg balance scale (+exp)

A vs 0		
Onigbinde et al. (2009) RCT (4) Nstart=17 Nend=17 TPS=Not reported A vs 0	E: Wobble Board exercises + Conventional Therapy C: Conventional Therapy Duration: 6wks	E vs C: Static Balance Eyes open (-) Eyes closed (+exp) Foursquare step test (+exp)
Balance-Focused Exercise Programs vs At-home Exercises		
Curuk & Aruin (2022) RCT crossover (8) Nstart=6 Nend=6 TPS=Chronic A vs B	E: Anticipatory postural adjustment and postural control exercises C: At-home self-guided general mobility exercise program Duration: 4wks, 1wk washout period	E vs C: COP displacement (+exp) Mini-BESTest score (-) ABC Scale (-)
Balance Training Using SMART Balance Master vs Conventional Rehabilitation		
Rao et al. (2013) RCT (5) Nstart=28 Nend=28 TPS=Acute A + B vs A Also in Table 15 (Biofeedback)	E: Balance training + postural control visual biofeedback (SMART Balance master) C: Conventional PT + balance training Duration: 60min/d, 5d/wk, 2wks + 30min/d, 1d/wk, 2wks conventional PT & 3session balance training/balance training with visual biofeedback with BWS	E vs C: Functional Independence Measure (-) Fugl-Meyer Balance scores (-) Fugl-Meyer lower extremity assessment (-)
Chen et al. (2002) RCT (4) Nstart=41 Nend=41 TPS=Subacute A + B vs 0 Also in Table 15 (Biofeedback)	E: Balance training + postural control visual biofeedback (SMART Balance master) C: Conventional rehabilitation Duration: Not Specified	E vs C: Functional Independent Measure selfcare and sphincter control (No stats) mobility and locomotion (No stats) static balance maximal stability (No stats) ankle strategy (No stats) center of gravity alignment (No stats) dynamic balance axis velocity (No stats) directional control (No stats) end point excusion (No stats)
Geiger et al. (2001) RCT (5) Nstart=13 Nend=13 TPS=Subacute A vs 0 Also in Table 15 (Biofeedback)	E: Physical therapy + visual biofeedback (SMART Balance master forceplate) C: Physical therapy Duration: 50min/d, 2-3d/wk for 4wks	E vs C: Berg Balance Scale (-) Timed Up & Go Test (-)
Walker et al. (2000) RCT (4) Nstart=54 Nend=46 TPS=Subacute A + B vs A + C vs 0 Also in Table 15 (Biofeedback)	E1: Balance training + Visual feedback E2: Balance training + Verbal and tactile cues C: Conventional rehabilitation Duration: 30min/d, 5d/wk for 3- 8wks Balance training, 120min/d, 5d/wk Conventional rehabilitation	E1 vs E2 vs C: Postural sway Eyes open (-) Eyes closed (-) Berg Balance Scale (-) Timed Up & Go Test (-) 10-m walk test (-)

Non-Supportive Balance Trainers with Feedback vs Conventional Therapy or Balance Training		
Komiya et al. (2021) RCT (6) Nstart=30 Nend=27 TPS=Chronic A + B vs A	E: Balance exercises + Real- time position feedback system+ standard physical therapy C: Balance exercise using polyurethane mat + standard physical therapy Duration: 2min/d, 2d/wk for 6wks balance exercise & 2d/wk for 6wks physical therapy	E vs C: Isometric Muscle Strength Knee extension Paretic (-) Non Paretic (-) Short Physical Performance Battery (-) Timed Up and Go Test (+exp) Center of Pressure trajectory length (-) Modified Gait Efficacy Scale (+exp) Falls Efficacy (-)
Brunelli et al. (2020) RCT (5) Nstart=32 Nend=24 TPS=Acute A vs 0	E: Computerized balance training + conventional physiotherapy C: Conventional physiotherapy Duration: 80min/d, 5d/wk for 4wks	E vs C: Berg Balance Scale (+exp) Tinetti Balance Scale (+exp) Two minutes walk test (+exp) Barthel Index (-) Clinical Test of Sensory Integration and Balance 1 (-) 2 (+exp) 3 (-) 4 (+exp)
Zhang et al. (2020) RCT (5) Nstart=40 Nend=40 TPS=Subacute A + B vs C	E: Conventional balance training + visual balance training with Pro-kin system + Game training C: Conventional balance training Duration: 20min/d, 5d/wk for 3wks	E vs C: Berg Balance Scale (+exp) Timed Up & Go Test (+exp) Functional Ambulation Classification (+exp) Barthel Index (+exp) Pro-kin system parameters Perimeter EO (+exp) Ellipse area EO (+exp) Perimeter EC (+exp) Ellipse area EC (+exp)
Maciaszek. (2018) RCT (4) Nstart=20 Nend=20 TPS=Subacute A vs 0 Also in Table 15 (Biofeedback)	E: Posturographic platform biofeedback training C: Standard hospital treatment Duration: 15d	E vs C: One-leg standing test (+exp) Timed Up & Go Test (+exp)
Balance Training with Visual Biofeedback vs Conventional Therapy or Balance Training		
Aphiphaksakul et al. (2022) RCT (7) Nstart=32 Nend=32 TPS=Subacute A vs B	E: Sitting balance training with balance disc and smartphone app + conventional home rehab C: Conventional home rehab Duration: 60 min/d, 5d/wk, 4wks	E vs C: FIST(-) PASS total(-) maintaining posture(-) changing posture(+exp) BI(+exp)
Noh et al. (2019) RCT (8) Nstart=24 Nend=24 TPS=Subacute A vs 0	E: 3D balance training using visual feedback + Conventional therapy C: Conventional therapy Duration: 30min/d conventional therapy & 30min/d space balance training, 5d/wk, for 4wks	E vs C: Berg Balance Scale (+exp) Gait speed (+exp) Cadence (+exp) Step length (+exp) Double-limb support period (+exp)

Also in Table 15 (Biofeedback)		Activity-specific balance confidence (+exp)
James et al. (2017) RCT (6) Nstart=10 Nend=10 TPS=Acute A1 vs A2 Also in Table 15 (Biofeedback)	E: Gaming Assisted Visual feedback for balance training + Conventional therapy C: Balance training exercises + Conventional therapy Duration: 60min/d, 2sessions/d, 4d (8 sessions total)	E vs C: Berg Balance Scale (+exp) AP-Postural sway (-) Lat-Postural Sway (+exp) Stance symmetry (+exp) Active ankle ROM dorsiflexion (-) Active ankle ROM plantarflexion (+exp) Lateral reach test (-)
Ghomashchi (2016) RCT (3) Nstart=31 Nend=31 TPS=Chronic A + B vs A Also in Table 15 (Biofeedback)	E: Balance training using Biodex stability system + visual biofeedback C: Balance training Duration: 1hr/d, 3d/wk for 4wks	E vs C: Postural balance (-) Centre of pressure (-)
Ordahan et al. (2015) RCT (4) Nstart=50 Nend=50 TPS=Subacute A + B vs 0 Also in Table 15 (Biofeedback)	E: Balance training + postural control visual biofeedback + conventional rehabilitation C: Conventional rehabilitation Duration: 20min/d, 5d/wk for 6wks Balance Training & 30min/d, 5d/wk, for 6wks Conventional Program	E vs C: Berg Balance Scale (+exp) Timed Up & Go Test (+exp) Functional Independence Measure (-)
Ko et al. (2015) RCT (4) Nstart=52 Nend=40 TPS=Acute A vs 0 Also in Table 15 (Biofeedback)	E: Space balance 3D training using visual feedback program + Conventional rehabilitation C: Conventional rehabilitation Duration: 30min/d, 5d/wk for 3wks	E vs C: Berg Balance Scale (-) Timed Up & Go Test (-) Postural Assessment Scale for Stroke (-)
De Nunzio et al. (2014) RCT (7) Nstart=37 Nend=37 TPS=Acute A vs B Also in Table 15 (Biofeedback)	E: Balance Platform Training with Audio-visual Feedback + Rehabilitation program C: Rehabilitation program + postural training with physiotherapy Duration: 60min, 6d/wk, for 2wks rehabilitation program & 30min of postural training	E vs C: Standing Balance Score (-) Berg Balance Score (-) Performance-Oriented Mobility Assessment (-) Fullerton's Advanced Balance Scale (-) Functional Independence Measure (-) Centre of Pressure (-)
Lee et al. (2013e) RCT (4) Nstart=22 Nend=22 TPS=Chronic A + B vs 0 Also in Table 15 (Biofeedback)	E: Balance training + postural control visual biofeedback C: Conventional physiotherapy Duration: 60min/d, 5d/wk for 4wks	E vs C: Static balance (+exp) Dynamic balance (+exp)
Yoon et al. (2013) RCT (2) Nstart=24 Nend=24 TPS=Chronic A1 + B vs A2 + B vs A Also in Table 15 (Biofeedback)	E1: Balance training + self- controlled postural control visual biofeedback E2: Balance training + no control over postural control visual biofeedback C: Balance training Duration: 2d	E1/E2 vs C: Postural sway:(+exp1, +exp2) E1 vs E2: Postural Sway (+exp1)

Varoqui et al. (2011) RCT (6) Nstart=24 Nend=23 TPS=Subacute A1 + B vs A2 + B vs C Also in Table 15 (Biofeedback)	E1: Balance training + postural control visual biofeedback from unaffected side + physiotherapy E2: Balance training + postural control visual biofeedback from affected side +physiotherapy C: Stand-up task + physiotherapy Duration: 10min/session, 8session/28d	E1/E2 vs C: Postural Assessment Scale for Stroke (-) Berg Balance Scale (-) modified Ashworth scale (-) Motor weakness (-) Functional Ambulation Category (-) Functional Independence Measure Motor (+exp1, +exp2) Cognitive (-)
Yavuzer et al. (2006a) RCT (6) Nstart=50 Nend=41 TPS=Chronic A vs 0 Also in Table 15 (Biofeedback)	E: Force platform biofeedback balance training + Conventional rehabilitation C: Conventional rehabilitation Duration: 2-5hr/d, 5d/wk, for 8wks Conventional rehabilitation & 15min/d, 5d/wk for 3wks Balance training	E vs C: Walking Velocity (-) Cadence (-) Step length (-) Single-Support Time (-) Step Length Asymmetry (-) Single-support Time Asymmetry (-) Pelvic Tilt (-) Pelvis Obliquity (+exp) Pelvic rotation (-) Sagittal Plane Total Excursion Knee (-) Hip (-) Ankle (-) Peak Hip Extensor Moment (-) Peak Hip Abductor Moment (-) Peak Knee Extensor Moment (-) Peak Ankle Plantar Flexor Moment (-) Vertical Ground Reaction Force (+exp)
Sackley & Lincoln (1997) RCT (6) Nstart=26 Nend=24 TPS=Subacute A + B vs B Also in Table 15 (Biofeedback)	E: Visual feedback + Nottingham Balance Platform training + physical therapy C: Sham visual feedback + Nottingham Balance Platform training + physical therapy Duration: 60min/d, 3d/wk, for 4wks	E vs C: Balance co-efficient (+exp) Rivermead Motor assessment (+exp) Leg and trunk (-) Gross function (+exp) Nottingham 10-point Activities of Daily Life scale (+exp) Stance symmetry (+exp) Sway (+exp)
Standing Practice vs Conventional Therapy		
Inoue et al. (2021) RCT (8) Nstart=52 Nend=52 TPS=Acute A1 vs A2	E: Standing exercise with weight shifting to the nonparetic side (on an inclined surface that was elevated 5 degrees to the nonparetic side) + Conventional physiotherapy C: Standing exercise with weight shifting to the nonparetic side (on a flat surface) + Conventional physiotherapy 30 exercises sessions/d for 5d interventions & 60min/session conventional physiotherapy	E vs C: Berg Balance Scale (-) Posturographic examination Static standing (-) Maximum lateral weight shifting to nonparetic side (-) Maximum lateral weight shifting to paretic side (-) Stroke Impairment Assessment Set (-) Trunk Control Test (-) Trunk Impairment Scale (-) Functional Ambulation Category (+exp) Functional Independence Measure motor items (-)

Allison et al. (2007) RCT (8) Nstart=17 Nend=14 TPS=Acute A vs 0	E: Standing practice + Conventional therapy C: Conventional therapy Duration: 45min/d, 5d/wk for 2- 4wks	E vs C: Berg Balance Scale (-) Rivermead Motor Assessment (-) Trunk Control Test (-)
Wong et al. (1997) RCT (5) Nstart=60 Nend=60 TPS=Acute A + B vs C Also in Table 15 (Biofeedback)	E: Standing practice + Force platform biofeedback C: Standing training table Duration: 60min/d, 5d/wk, for 3- 4wks	E vs C: Postural symmetry (+exp)
Perturbation Balance Trainers with Feedback vs Conventional Therapy or Balance Training		
An et al. (2021) RCT (8) Nstart=30 Nend=30 TPS=Subacute A + B + C + D vs E Also in Table 15 (Biofeedback)	E: Whole-Body Tilting Postural Training (Visual feedback monitor + Trunk sensor + 8- direction body tilt + Spine balance 3D) C: General Postural Training Duration: 30min/session, 2sessions/d, 5d/wk, for 3wks	E vs C: Burke Lateropulsion Scale (+exp) Postural Assessment Scale for Stroke (+exp) Berg Balance Scale (+exp) Korea-Modified Barthel Index (+exp) Fugl-Meyer Assessment (+exp)
Jung et al. (2021) RCT (7) Nstart=24 Nend=24 TPS=Subacute A vs B Also in Table 4 (Trunk Training)	E: Space Balance 3D system for active trunk training + conventional physical and occupational therapy C: General trunk training + Conventional physical and occupational physiotherapy Duration: 30min/d, 5d/wk, for 3wks	E vs C: Trunk Impairment Scale (+exp) Trunk Flexion muscle strength (+exp) Trunk Extension muscle strength (+exp) Static balance (+exp) Brunel Balance Assessment (+exp)
Thijs et al. (2021) RCT (8) Nstart=30 Nend=29 TPS=Chronic A vs 0	E: Technology-supported sitting balance therapy + conventional therapy C: Conventional therapy Duration: 30-120min/d, 3d/wk, for 4wks usual care & 50min/d, 3-4d/wk, for 4wks (12 in total) sitting balance therapy	E vs C: Trunk Impairment Scale (+exp) Modified Functional Reaching Test (-) Functional Ambulation Categories (-) 10 Metre Walk Test Max speed (+exp) Comfortable speed (-) Two Minute Walk Test (-) Fugl-Meyer Assessment of Lower Extremity (-) Berg Balance Scale (+exp) Functional Independence Measure (-) Modified Barthel Index (-) Trunk and leg strengths (-) Modified Ashworth Scale (-)
Perturbation Balance Trainers vs Conventional Therapy or Balance Training		
Lanza et al. (2024) Feasibility/pilot RCT (4) Nstart=30 Nend=22 TPS=Chronic A vs B	E: Pertubation training (PERT) C: Voluntary step training (VOL) Duration: 3d/wk, 6 wks	E vs C: Community Balance and Mobility Scale (-) Activities-Specific Balance Confidence Scale (-) step onset time (-) step clearance (-0) step length (-) step velocity (-)

Shen et al. (2023) RCT (7) Nstart=40 Nend=40 TPS=Subacute A vs B	E: Dynamic motion instability training + Conventional rehabilitation C: Conventional rehab + balance training Duration: 50min/d(30min conventional + 20min DMIST/balance training), 5d/wk, 8wks	E vs C: FMA-LE(+exp) BBS(-) Gait speed(+exp) Stride length(+exp)
Dusane & Bhatt (2022) RCT (5) Nstart=49 Nend=45 TPS=Chronic A + B vs A	E: Slip adaptation training on an overground perturbation system (8 unexpected overground, nonparetic-side gait-slips + 2 paretic-side slips) C: Slip adaptation training an overground perturbation system (2 paretic-side slips) Duration: single time	E vs C: Falls between Paretic Slip 1 (-) Falls Between Paretic Slip 2 (-) Post Slip Stability at Touchdown at Paretic Slip 1 (-) Post Slip Stability at Touchdown at Paretic Slip 2 (-) Max Heel Velocity at Paretic Slip 1 and 2 (-) Backwards loss of balance (-) Pre-slip stability at touchdown (-)
Chayasit et al. (2022) RCT (5) Nstart=34 Nend=33 TPS=Chronic A vs B	E: Voluntary-induced stepping response (VSR) C: DynSTABLE perturbation training (DST) Duration: 60min, single session training	E vs C: Step length(-) Step width(-) COM position at the 1st stepping foot touchdown (+con) Number of protective steps per trial (No stats) Choice of protective leg stepping (No stats) Grasping events (No stats) Loss of balance events (No stats)
Yadav et al. (2020) RCT (4) Nstart=133 Nend=110 TPS=Acute A1 vs A2 vs B1 vs B2 Also in Table 27 (Electromechanical and Robotic Devices)	E1: Haemorrhagic Stroke Erigo Robotic Tilt Table E2: Ischemic Stroke Erigo Robotic Tilt Table C1: Haemorrhagic Stroke Conventional Care C2: Ischemic Stroke Conventional Care Duration: 50-60min, 6d/wk, 30d	E vs C: For haemorrhagic group National Institutes of Health Stroke Scale (+exp) Mini Mental Scale Examination (-) Modified Ashworth Scale (+exp) SF-36 Quality of Life (+exp) Medical Research Council (+exp) For Ischemic group National Institutes of Health Stroke Scale (-) Mini Mental Scale Examination (-) Modified Ashworth Scale (-) SF-36 Quality of Life (-) Medical Research Council (-)
Schinkel-Ivy et al. (2019) RCT (6) Nstart=43 Nend=16 TPS=Chronic A vs 0	E: Perturbation-Based Balance Training C: Conventional care Duration: 60min/d, 2d/wk, for 6wks	E vs C: Reactive Stepping (-) Frequency of extra steps (-) Frequency of lateral steps (-) Frequency of stepping with more affected limb (-) Frequency of foot collisions (-) Step Timing (-) Foot-off time (-) Swing time (-)
Handelzalts et al. (2019) RCT (6)	E: Perturbation-based balance training + conventional care	E vs C: Multistep threshold Forward (+exp)

Nstart=34 Nend=32 TPS=Subacute A vs B + C	C: Weight shifting + Gait training without perturbation + conventional care Duration: 12 sessions, 30min/d, for 2.5wks	Backward (+exp) Toward the paretic side (-) Toward the non-paretic side (-) Fall threshold (-) Fugl-Meyer assessment Lower Extremity (-) Berg balance scale (-) 10m Walk test (-) 6min Walk test (-) Activity-specific Balance Confidence scale (-)
Mansfield et al. (2018) RCT (8) Nstart=88 Nend=83 TPS=Chronic A vs B	E: Perturbation-based balance training C: Traditional balance training Duration: 60min/d, 2d/wk, for 6wks	E vs C: Fall rates (after 1 year) (-) Berg balance scale (-) Mini-Balance Evaluation Systems test (-) Anticipatory balance control (-) Reactive balance control (+exp) Sensory orientation (+con) Gait (-) Timed Up & Go (-) Activities-specific Balance Confidence (-) Physical Activity Scale for Individuals with Physical Disabilities (-) Subjective Index of Physical and Social Outcome (-)
Yadav et al. (2018) RCT (4) Nstart=30 Nend=30 TPS=Acute A + B vs 0 Also in Table 27 (Electromechanical and Robotic Devices)	E: Robotic Tilt table + Upper extremity exercises C: Conventional therapy Duration: 50-60min/d, 6d/wk, for 4wks	E vs C: SF-36 Quality of life (+exp) Medical Research council Muscle scale (+exp)
Goljar et al. (2010) RCT (6) Nstart=44 Nend=39 TPS=Subacute A vs 0	E: Balance trainer mechanical device + Conventional care C: Conventional balance training + Conventional care Duration: 45 mins (20min balance trainer/ conventional balance training+ 20 min physical therapy), 5d/wk, 4wk	E vs C: Berg Balance Scale (-) Timed Up and Go Test (-) 10-metre walk test (-) Single limb standing duration (-)
Balance Training with Visual Deprivation vs Balance Training with Visual Cues		
Jeong et al. (2024) RCT (5) Nstart=45 Nend=39 TPS=Chronic A1 vs A2 vs 0 Also in Table 15 (Biofeedback)	E1: Visual Deprivation Group Balance Training Group + Conventional Therapy; E2: Visual Feedback Balance Training Group + Conventional Therapy C: Conventional Therapy Duration: 30 min, 5x/wk, for 3 wks	E1 vs E2: (LOS = Limit of stability) LOS-Left (+exp) LOS-Right (+exp) LOS-Forward (+exp) LOS-Back (+exp) LOS-Total (+exp) BBS (-) E vs C: LOS-Left (+exp) LOS-Right (+exp) LOS-Forward (+exp) LOS-Back (+exp) LOS-Total (+exp)

		BBS (+exp1, +exp 2) FSST (+exp1) TUG (+exp1)
Nam et al. (2022a) RCT (5) Nstart=45 Nend=41 TPS=Chronic A + B + C vs A + B vs B	E1: Visual cue deprivation + balance training + head control E2: Visual cue deprivation + Balance training C: Balance training Duration: 30 mins/d, 3d/wk, 4wks	E1 vs C: Limit of stability Left (+exp1) Right (+exp1) forward (+exp1) back (+exp1) Berg balance scale (+exp1) Stride time (-) Stride length (+exp1) Cadence (+exp1) E2 vs C: Limit of stability Left (+exp2) Right (+exp2) forward (+exp2) back (+exp2) Berg balance scale (-) Stride time (-) Stride length (+exp2) Cadence (-) E1 vs E2: Limit of stability Left (-) Right (-) forward (-) back (-) Berg balance scale (+exp1) Stride time (-) Stride length (-) Cadence (-)
Narendra et al. (2013) RCT (4) Nstart=30 Nend=30 TPS=Not reported A vs B	E: Balance exercises with blindfold C: Balance exercises with free vision Duration: 45-60min/d, 5d/wk for 6wks	E vs C: Berg Balance scale (+exp) Stroke specific Quality of Life scale (-) Family role (-) Mobility (-) Self-care (-) Upper extremity Function/productivity (-) Rivermead mobility index (-)
Yelnik et al. (2008) RCT (7) Nstart=68 Nend=67 TPS=Chronic A + B vs 0	E: Balance training + Visual deprivation C: Conventional rehabilitation Duration: 60-70 min/d, 5d/wk, 4 wks	E vs C: Berg Balance Scale (-) 10m walk (-) Percentage of double stance phase (-) Time to climb 10 steps and return (-) Daily time of walking (-) Security sensation during walking (-) Number of falls since stroke (-) Functional Independence Measure (+exp) Nottingham Health Profile (-) Posturographic limits of stability (-)

Bonan et al. (2004) RCT (7) Nstart=20 Nend=20 TPS=Chronic A1 vs A2	E: Vision deprived balance rehabilitation C: Balance rehabilitation Duration: 60min/d, 5d/wk, for 4wks	E vs C: Sensory Organization Test (+exp) Self-Assessed VAS – ease of gait (-) Timed Stair Climbing (-) Gait Velocity (-) Nottingham Health Profile (-)
Balance Training with Kinesthetic Ability Training Device vs Conventional Rehabilitation		
Alptekin et al. (2008) RCT (6) Nstart=30 Nend=30 TPS=Chronic A vs 0 Also in Table 15 (Biofeedback)	E: Balance training with kinesthetic ability training device + conventional rehabilitation C: Conventional rehabilitation Duration: 2-3h/d, 5d/wk, for 4wks	E vs C: Fugl-Meyer Assessment lower extremity (-) balance (+exp) Kinesthetic Ability Trainer (+exp) static balance (+exp) dynamic balance (+exp) Functional Independence Measure motor (-) locomotion (-)
Balance Training with Full Rest Periods vs Balance Training with Short Rest Periods		
Elsner et al. (2018) RCT (8) Nstart=20 Nend=20 TPS=Subacute A1 vs A2	E: Full rest during Balance training C: Short rest during Balance training Duration: E: 4min rest in between exercises (full rest time), 2min/exercise for 7 exercises C: 1min rest in between exercises (short rest time), 2min/exercise for 7 exercises	E vs C: One-leg standing time (-) Tandem standing time (-)
Balance Training with Muscle Vibration vs Conventional Rehabilitation		
Merkert et al. (2011) RCT (3) Nstart=66 Nend=48 TPS=Acute A + B vs C Also in Table 31 (Muscle Vibration)	E: Vibrosphere (balance training + whole body vibration) + conventional geriatric rehabilitation. C: Conventional geriatric rehabilitation. Duration: 15 sessions of Vibrosphere training	E vs C: Berg Balance scale (-) Functional test of Lower trunk stability (-) Tinetti Gait test (-) Timed Up and Go (-) Mini-mental State examination (-) Barthel index (-) Transfer (+exp) Dressing (+exp) Feeding (+exp) Walking (-) Climbing stairs (-)
Balance Training with Biofeedback vs Balance Training		
Martino Cinnera et al. (2024) Feasibility/pilot RCT (9) Nstart=21 Nend=21 TPS=Chronic A vs B	E: sensor-based balance training C: Conventional balance training Duration: 30 mins/d, 2-3 ds/wk, 4wks [total 10 sessions]	E vs C: Berg balance scale (-) Canadian neurological scale (-) Barthel index (-) Rivermead mobility index (-) National institute of health stroke scale (-) Length of center of pressure open-eyes (+exp) closed-eyes (-) Pittsburgh Rehabilitation Participation Scale (+exp)
Kim et al. (2022e) RCT crossover (6)	E1: Pressure sensor-based vibrotactile biofeedback	E1/E2 vs C: Sway length (+exp1/2)

Nstart=24 Nend=24 TPS=Chronic A vs B vs C Also in Table 15 (Biofeedback)	E2: Visual biofeedback providing posture information C: Standing without biofeedback Duration: 1d, 24hr washout period	Sway velocity (+exp1/2) Weight distribution symmetric index (+exp1/2) E1 vs E2: Sway length (+exp1) Sway velocity (+exp1) Weight distribution symmetry index (+exp1)
Lupo et al. Nstart=21 Nend=21 TPS=Subacute A + B vs A vs 0 Primary listing: Table 28 (Functional Electrical Stimulation)	C: Usual care Duration: 1hr/d, 4d/wk for 2wks interventions	Weight through affected limb in parallel stance (-) Weight transferred onto affected limb in parallel stance (-) Weight transferred onto affected limb in stride stance (-) Berg Balance Scale Rivermead Mobility Index (-) 10-Metre Walk Test Normal walking (-) Fast walking (-)
Jiejiao et al. (2012) RCT (8) Nstart=92 Nend=85 TPS=Chronic A + B vs A Primary listing: Table 16 (Dual-Task Training)	E: Balance training + cognitive training C: Balance training Duration: 40min/d, 5d/wk for 8wks	E vs C: Center of Pressure (-) Mediolateral Sway Distance (+exp) Anteroposterior Eyes Open (+exp) Eyes Closed (-)
Seo et al. (2012) RCT (4) Nstart=40 Nend=40 TPS=Chronic A vs B Primary listing: Table 16 (Dual-Task Training)	E: Dual-task balance training C: Single-task balance training Duration: 30min/d, 5d/wk for 4wks	E vs C: Sway path (-) Sway area (+exp) Max velocity (+exp)
Cho et al. (2012) RCT (5) Nstart=24 Nend=22 TPS=Chronic A vs 0 Primary listing: Table 26 (Virtual Reality)	E: Wii-based balance training C: Conventional rehabilitation Duration: 30min/d, 3d/wk, for 6wks virtual reality balance training & 1hr/d, 5d/wk, for 6wks conventional care	E vs C: Antero-posterior postural sway velocity (-) Medio-lateral postural sway velocity (-) Berg Balance Scale(+exp) Timed up and Go test(+exp)
Kim et al. (2012c) RCT (4) Nstart=20 Nend=17 TPS=Chronic A vs B Primary listing: Table 26 (Virtual Reality)	E: Wii-based balance training C: Control group Duration: 30min/d, 3d/wk for 3wks	E vs C: Postural Assessment Scale (+exp) Modified Motor Assessment Scale (+exp) Functional Independence Measure (-)
Lee et al. (2012) RCT (8) Nstart=40 Nend=40 TPS=Chronic A vs 0 Primary listing: Table 26 (Virtual Reality)	E: Balance training with Balance Control Trainer C: Conventional rehabilitation Duration: 60min/d, 5d/wk, for 4wks conventional rehabilitation & 20min/d, 5d/wk, for 4wks balance training	E vs C: Berg Balance Scale (+exp) Timed Up & Go Test (+exp) Functional Ambulation Categories (+exp) Modified Barthel Index (-) 10-Metre Walking Test (+exp) Manual Muscle Test (-)
Jung et al. (2011) RCT (4)	E: 3D balance exercises (3D Thera-Balance) with visual feedback	E vs C: Berg Balance Scale (+exp)

Nstart=22 Nend=22 TPS=Chronic A vs B Primary listing: Table 26 (Virtual Reality)	C: Weight shifting exercises Duration: 50min/d, 5d/wk for 6wks	10-Metre Walk Test (-)
Kim et al. (2009) RCT (6) Nstart=24 Nend=24 TPS=Chronic A vs 0 Primary listing: Table 26 (Virtual Reality)	E: Virtual reality-based balance training C: Conventional therapy Duration: 30min/d, 4d/wk, for 4wks VR-balance training & 40min/d, 4d/wk, for 4wks Conventional therapy	E vs C: Berg Balance Scale (+exp) Static balance (-) Sway area (-) Sway path (-) Maximal velocity (-) Dynamic balance AP angle (+exp) ML angle (+exp) Modified Motor Assessment Scale (+exp) 10-Metre Walk Test (+exp) Cadence (+exp) Step time (+exp) Swing time (-) Stance time (-) Single Limb Support time (-) Double Limb Support time (-) Step length (+exp) Stride length (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Balance-Focused Exercise Programs may produce greater improvements in motor recovery than Conventional Rehabilitation.	2	Tan et al. 2023; Alptekin et al. 2008
1b	There is conflicting evidence about the effect of Balance Training with Posture Changes when compared to Balance Training for improving motor recovery.	1	Jiang et al. 2021
1b	Shoulder elevation posture change with balance training and Conventional training may produce greater improvements in motor recovery than Back posture change with balance training and Conventional training.	1	Jiang et al. 2021
2	Balance Training Using SMART Balance Master may not have a difference in efficacy when compared to Conventional Rehabilitation for improving motor recovery.	1	Rao et al. 2013
1a	Balance Training with Visual Biofeedback may produce greater improvements in motor recovery than Conventional Therapy or Balance Training.	2	Varoqui et al. 2011; Sackley & Lincoln 1997

1a	Standing Practice may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	2	Inoue et al. 2021; Allison et al. 2007
1a	There is conflicting evidence about the effect of Perturbation Balance Trainers with Feedback when compared to Conventional Therapy or Balance Training for improving motor recovery.	2	An et al. 2021; Thijs et al. 2021
1a	There is conflicting evidence about the effect of Perturbation Balance Trainers when compared to Conventional Therapy or Balance Training for improving motor recovery.	3	Shen et al. 2023; Yadav et al. 2020; Handelzalts et al. 2019
1b	Balance Training with Kinesthetic Ability Training Device may produce greater improvements in motor recovery than Conventional Rehabilitation.	1	Alptekin et al. 2008
1a	Balance Training with Biofeedback may not have a difference in efficacy when compared to Balance Training for improving motor recovery.	3	Martino Cinnera et al. 2024; Lupo et al. 2018; Eser et al. 2008
1b	Robotic Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	1	Inoue et al. 2022b
1b	Strength or Resistance Training with Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	1	Vahlberg et al. 2017a
1b	Balance Training may not have a difference in efficacy when compared to No Training for improving motor recovery.	1	Lisinski et al. 2012
1b	There is conflicting evidence about the effect of Class-Based Body Awareness Training when compared to Home-Based Body Awareness Training for improving motor recovery.	1	Serrada et al. 2022
1b	There is conflicting evidence about the effect of Robot assisted gait training with Traditional balance training when compared to Traditonal balance training for improving motor recovery.	1	Gunduz et al. 2024
1b	Virtual balance training (VBT) with Conservative training may not have a difference in efficacy when compared to Conservative training (traditional rehab techniques) for improving motor recovery.	1	Kilinc et al. 2023
1b	Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may produce greater improvements in motor recovery than Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy.	1	Mihai et al. 2022
1b	Virtual reality balance training with Nintendo Wii with conventional physical therapy may not have a difference in efficacy when compared to Conventional physical therapy for improving motor recovery.	1	Marques-Sule et al. 2021
1b	Progressive resistance with balance training and motivational session may not have a difference in efficacy when compared to Usual activity for improving motor recovery.	1	Vahlberg et al. 2017a
1b	Computer-generated interactive visual feedback balance training with Physical therapy may produce greater improvements in motor recovery than Mirror visual feedback balance training with Physical therapy.	1	Yang et al. 2015
2	Balance training with cognitive training may not have a difference in efficacy when compared to Balance training with balance board for improving motor recovery.	1	Choi et al. 2015b

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Task Specific Balance Training may not have a difference in efficacy when compared to Upper Limb Exercise for improving biomechanical gait measures.	1	Pang et al. 2018
1a	Balance Training with Visual Biofeedback may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving biomechanical gait measures.	4	Noh et al. 2019; James et al. 2017; Yavuzer et al. 2006a; Sackley & Lincoln 1997
2	Standing Practice may produce greater improvements in biomechanical gait measures than Conventional Therapy.	1	Wong et al. 1997
1a	Perturbation Balance Trainers may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving biomechanical gait measures.	4	Lanza et al. 2024; Shen et al. 2023; Chayasit et al. 2022; Schinkel-Ivy et al. 2019
1b	Balance Training with Visual Deprivation may not have a difference in efficacy when compared to Balance Training with Visual Cues for improving biomechanical gait measures.	2	Nam et al. 2022a; Yelnik et al. 2008
2	Visual cue deprivation with balance training and head control may not have a difference in efficacy when compared to Visual cue deprivation with Balance training for improving biomechanical gait measures.	1	Nam et al. 2022a
1a	Vestibular Training may not have a difference in efficacy when compared to Conventional Therapy for improving biomechanical gait measures.	4	Cui et al. 2024; Son et al. 2024; Zhao et al. 2022b; Tramontano et al. 2018
2	Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may produce greater improvements in biomechanical gait measures than gaze stabilization exercises with neurodevelopmental treatment.	1	Cui et al. 2024
2	Balance Training with Fresnel Prism Glasses may not have a difference in efficacy when compared to Balance and Walking Training for improving biomechanical gait measures.	1	Ha & Sung 2020
1b	There is conflicting evidence about the effect of Balance Training when compared to No Training for improving biomechanical gait measures.	1	Lisinski et al. 2012
1b	Perturbation Balance Training may not have a difference in efficacy when compared to Proprioceptive Neuromuscular Facilitation for improving biomechanical gait measures.	1	Adhikari et al. 2024
2	Vestibular rehabilitation therapy + Conventional physical therapy may not have a difference in efficacy when compared to Conventional care for improving biomechanical gait measures.	1	Elhamrawy et al. 2021
2	Gait-slip perturbation with FES to paretic quadriceps muscle may produce greater improvements in biomechanical gait measures than Gait-slip perturbations.	1	Purohit et al. 2024
1b	Visual feedback with Unstable surface balance training may not have a difference in efficacy when compared to Conventional physical therapy for improving biomechanical gait measures.	1	Yeo et al. 2023
1b	Visual feedback with Unstable surface balance training may not have a difference in efficacy when compared to Unstable surface balance training for improving biomechanical gait measures.	1	Yeo et al. 2023
1b	Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not have a difference in efficacy when compared to Sham taping with exercise training for improving biomechanical gait measures.	1	Wang et al. 2022c

1b	Wii-based balance training may not have a difference in efficacy when compared to Conventional rehabilitation for improving biomechanical gait measures.	1	Barcala et al. 2013
1b	Standing balance exercises with functional electrical stimulation may not have a difference in efficacy when compared to Usual care for improving biomechanical gait measures.	1	Kunkel et al. 2013
1b	Virtual reality-based balance training may not have a difference in efficacy when compared to Conventional therapy for improving biomechanical gait measures.	1	Kim et al. 2009

BIOMECHANICAL BALANCE MEASURES

2	Strength or Resistance Training with Balance Training may produce greater improvements in muscle strength than Conventional Therapy.	1	Sekhar et al. 2013
1b	Perturbation treadmill training group may not have a difference in efficacy when compared to Non-perturbation treadmill training group for improving muscle strength.	1	Esmaeili et al. 2020
2	There is conflicting evidence about the effect of Tetrax biofeedback balance training with Conventional care when compared to Conventional care for improving muscle strength.	1	Hung et al. 2016b
1b	Balance training with Balance Control Trainer may not have a difference in efficacy when compared to Conventional rehabilitation for improving muscle strength.	1	Lee et al. 2012

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Balance Training with Visual Biofeedback may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving spasticity.	1	Varoqui et al. 2011
1b	Perturbation Balance Trainers with Feedback may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving spasticity.	1	Thijs et al. 2021
2	There is conflicting evidence about the effect of Perturbation Balance Trainers when compared to Conventional Therapy or Balance Training for improving spasticity.	1	Yadav et al. 2020

1b	Virtual balance training (VBT) with Conservative training may not have a difference in efficacy when compared to Conservative training (traditional rehab techniques) for improving spasticity.	1	Kilinc et al. 2023
1b	Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may produce greater improvements in spasticity than Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy.	1	Mihai et al. 2022

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Balance Training with Visual Biofeedback when compared to Conventional Therapy or Balance Training for improving range of motion.	1	James et al. 2017
1b	There is conflicting evidence about the effect of Visual feedback with Unstable surface balance training when compared to Conventional physical therapy for improving range of motion.	1	Yeo et al. 2023
1b	There is conflicting evidence about the effect of Visual feedback with Unstable surface balance training when compared to Unstable surface balance training for improving range of motion.	1	Yeo et al. 2023
1b	Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may produce greater improvements in range of motion than Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy.	1	Mihai et al. 2022

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Balance Training with Posture Changes may produce greater improvements in neurophysiological measures than Balance Training.	1	Jiang et al. 2021
1b	Shoulder elevation posture change with balance training and Conventional training may produce greater improvements in neurophysiological measures than Back posture change with balance training and Conventional training.	1	Jiang et al. 2021
1b	Balance Training with transcutaneous electrical nerve stimulation may produce greater improvements in neurophysiological measures than Balance Training with Conventional Care.	1	Jung et al. 2016
1b	Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care may produce greater improvements in neurophysiological measures than Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care.	1	Jung et al. 2016
1b	Strength or Resistance Training with Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving neurophysiological measures.	1	Vahlberg et al. 2017a
1b	Balance Training with electromyography- triggered functional electrical stimulation and General Rehabilitation may produce greater improvements in neurophysiological measures than Balance Training without functional electrical stimulation with General Rehabilitation.	1	Lee et al. 2020b
1b	Progressive resistance with balance training and motivational session may not have a difference in efficacy when compared to Usual activity for improving neurophysiological measures.	1	Vahlberg et al. 2017a

2	There is conflicting evidence about the effect of Ankle Foot Orthosis (Joint type) with Balance Training when compared to No Orthotic with Balance Training for improving neurophysiological measures.	1	Lee et al. 2014c

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Ankle-Foot orthosis with Balance Training Shoes may produce greater improvements in aerobic measures than Ankle-Foot Orthosis with Regular Shoes.	1	Farmani et al. 2016

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Balance-Focused Exercise Programs may not have a difference in efficacy when compared to Conventional Rehabilitation for improving sensory and proprioceptive function.	1	Battesha et al. 2022
2	There is conflicting evidence about the effect of Non-Supportive Balance Trainers with Feedback when compared to Conventional Therapy or Balance Training for improving sensory and proprioceptive function.	1	Brunelli et al. 2020
1b	There is conflicting evidence about the effect of Perturbation Balance Trainers when compared to Conventional Therapy or Balance Training for improving sensory and proprioceptive function.	1	Mansfield et al. 2018
1b	Robotic Balance Training may produce greater improvements in sensory and proprioceptive function than Conventional Therapy.	1	De Luca et al. 2020
1b	Class-Based Body Awareness Training may not have a difference in efficacy when compared to Home-Based Body Awareness Training for improving sensory and proprioceptive function.	1	Serrada et al. 2022
2	Tetrax biofeedback balance training with Conventional care may produce greater improvements in sensory and proprioceptive function than Conventional care.	1	Hung et al. 2016b

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Balance-Focused Exercise Programs may not have a difference in efficacy when compared to Conventional Rehabilitation for improving activities of daily living.	1	Alptekin et al. 2008
1b	Task Specific Balance Training may not have a difference in efficacy when compared to Upper Limb Exercise for improving activities of daily living.	1	Pang et al. 2018
1b	Balance Training with Posture Changes may not have a difference in efficacy when compared to Balance Training for improving activities of daily living.	1	Jiang et al. 2021
1b	Shoulder elevation posture change with balance training and Conventional training may not have a difference in efficacy when compared to Back posture change with balance training and Conventional training for improving activities of daily living.	1	Jiang et al. 2021
2	Balance Training Using SMART Balance Master may not have a difference in efficacy when compared to Conventional Rehabilitation for improving activities of daily living.	2	Rao et al. 2013; Chen et al. 2002

2	Non-Supportive Balance Trainers with Feedback may produce greater improvements in activities of daily living than Conventional Therapy or Balance Training.	2	Brunelli et al. 2020; Zhang et al. 2020
1a	Balance Training with Visual Biofeedback may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving activities of daily living.	3	Aphiphaksakul et al. 2022; Ordahan et al. 2015; De Nunzio et al. 2014
1b	Standing Practice may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	1	Inoue et al. 2021
1a	Perturbation Balance Trainers with Feedback may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving activities of daily living.	2	An et al. 2021; Thijs et al. 2021
1b	Perturbation Balance Trainers may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving activities of daily living.	1	Mansfield et al. 2018
1b	Balance Training with Visual Deprivation may produce greater improvements in activities of daily living than Balance Training with Visual Cues.	1	Yelnik et al. 2008
1b	Balance Training with Kinesthetic Ability Training Device may not have a difference in efficacy when compared to Conventional Rehabilitation for improving activities of daily living.	1	Alptekin et al. 2008
2	There is conflicting evidence about the effect of Balance Training with Muscle Vibration when compared to Conventional Rehabilitation for improving activities of daily living.	1	Merkert et al. 2011
1a	Balance Training with Biofeedback may not have a difference in efficacy when compared to Balance Training for improving activities of daily living.	3	Martino Cinnera et al. 2024; Lupo et al. 2018; Eser et al. 2008
1b	Vestibular Training may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	1	Tramontano et al. 2018
1b	Robotic Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	1	Inoue et al. 2022b
1b	Trampoline Balance Training may not have a difference in efficacy when compared to Stable Surface Balance Training for improving activities of daily living.	1	Miklitsch et al. 2013
1a	Strength or Resistance Training with Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	2	Vahlberg et al. 2017a; Vahlberg et al. 2017b
1b	Vestibular rehabilitation may not have a difference in efficacy when compared to Convectional treatment for improving activities of daily living.	1	Dai et al. 2013
1b	Visual Scanning Training with Task-Specific Activities may not have a difference in efficacy when compared to Task-Specific Activities Alone for improving activities of daily living.	1	Batool et al. 2022
1b	Cognitive behaviour therapy + task-oriented balance training may produce greater improvements in activities of daily living than General health education + task-oriented balance training.	1	Liu et al. 2019
1b	Visual-spatial training exercises using specular vision training, mirror training, and target identification while walking + Conventional rehabilitation may produce greater improvements in activities of daily living than Trunk stabilization and weight transfer exercises + Conventional rehabilitation.	1	Tramontano et al. 2019

1b	Virtual balance training (VBT) with Conservative training may not have a difference in efficacy when compared to Conservative training (traditional rehab techniques) for improving activities of daily living.	1	Kilinc et al. 2023
1b	Virtual reality balance training with Nintendo Wii with conventional physical therapy may produce greater improvements in activities of daily living than Conventional physical therapy.	1	Marques-Sule et al. 2021
1b	Perturbation treadmill training group may not have a difference in efficacy when compared to Non-perturbation treadmill training group for improving activities of daily living.	1	Esmaeili et al. 2020
1b	There is conflicting evidence about the effect of Wii Fit-based balance exercise with conventional rehabilitation when compared to Conventional rehabilitation for improving activities of daily living.	1	Utkan Karasu et al. 2018
1b	There is conflicting evidence about the effect of Progressive resistance with balance training and motivational session when compared to Usual activity for improving activities of daily living.	1	Vahlberg et al. 2017a
1b	Virtual reality balance training with treatment may not have a difference in efficacy when compared to treatment for improving activities of daily living.	1	Lee et al. 2017d
1b	Dynamic balance training with Balance Trainer may produce greater improvements in activities of daily living than Static balance training with a conventional standing frame.	1	Braun et al. 2016
2	Balance training with cognitive training may not have a difference in efficacy when compared to Balance training with balance board for improving activities of daily living.	1	Choi et al. 2015b
2	Wii-based balance training may not have a difference in efficacy when compared to Progressive balance training for improving activities of daily living.	1	Yatar et al. 2015
1b	Video Game-Based Balance Training with conventional physical therapy may produce greater improvements in activities of daily living than Conventional physical therapy with Balance Training.	1	Morone et al. 2014
1b	Wii-based balance training may not have a difference in efficacy when compared to Conventional rehabilitation for improving activities of daily living.	1	Barcala et al. 2013
2	Wii-based balance training may not have a difference in efficacy when compared to Control group for improving activities of daily living.	1	Kim et al. 2012c
1b	Balance training with Balance Control Trainer may not have a difference in efficacy when compared to Conventional rehabilitation for improving activities of daily living.	1	Lee et al. 2012

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Balance Training with Posture Changes when compared to Balance Training for improving gait speed.	1	Jiang et al. 2021
1b	Shoulder elevation posture change with balance training and Conventional training may produce greater improvements in gait speed than Back posture change with balance training and Conventional training.	1	Jiang et al. 2021
2	Balance Training Using SMART Balance Master may not have a difference in efficacy when compared to Conventional Rehabilitation for improving gait speed.	2	Chen et al. 2002; Walker et al. 2000

1a	There is conflicting evidence about the effect of Balance Training with Visual Biofeedback when compared to Conventional Therapy or Balance Training for improving gait speed.	2	Noh et al. 2019; Yavuzer et al. 2006a
1b	There is conflicting evidence about the effect of Perturbation Balance Trainers with Feedback when compared to Conventional Therapy or Balance Training for improving gait speed.	1	Thijs et al. 2021
1a	Perturbation Balance Trainers may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving gait speed.	5	Lanza et al. 2024; Shen et al. 2023; Dusane & Bhatt 2022; Handelzalts et al. 2019; Goljar et al. 2010
1a	Balance Training with Visual Deprivation may not have a difference in efficacy when compared to Balance Training with Visual Cues for improving gait speed.	2	Yelnik et al. 2008; Bonan et al. 2004
1b	Balance Training with Biofeedback may produce greater improvements in gait speed than Balance Training.	1	Kim et al. 2022e
1a	Vestibular Training may produce greater improvements in gait speed than Conventional Therapy.	4	Cui et al. 2024; Son et al. 2024; Zhao et al. 2022b; Tramontano et al. 2018
2	Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may produce greater improvements in gait speed than gaze stabilization exercises with neurodevelopmental treatment.	1	Cui et al. 2024
2	Ankle-Foot orthosis with Balance Training Shoes may produce greater improvements in gait speed than Ankle-Foot Orthosis with Regular Shoes.	1	Farmani et al. 2016
1b	Strength or Resistance Training with Balance Training may produce greater improvements in gait speed than Conventional Therapy.	1	Vahlberg et al. 2017b
2	Balance Training with Fresnel Prism Glasses may produce greater improvements in gait speed than Balance and Walking Training.	1	Ha & Sung 2020
1b	Sensory Balance Training may not have a difference in efficacy when compared to Robot-assisted Stair Climbing for improving gait speed.	1	Gandolfi et al. 2019
1b	Balance Training may produce greater improvements in gait speed than No Training.	1	Lisinski et al. 2012
1b	Vestibular rehabilitation may not have a difference in efficacy when compared to Convectional treatment for improving gait speed.	1	Balci et al. 2013
1b	Class-Based Body Awareness Training may not have a difference in efficacy when compared to Home-Based Body Awareness Training for improving gait speed.	1	Serrada et al. 2022
2	Vestibular rehabilitation therapy + Conventional physical therapy may not have a difference in efficacy when compared to Conventional care for improving gait speed.	1	Elhamrawy et al. 2021
1b	Treadmill gait and balance training with Traditional gait and balance training may not have a difference in efficacy when compared to Traditional gait with balance training for improving gait speed.	1	Hu et al. 2023
1b	Visual feedback with Unstable surface balance training may produce greater improvements in gait speed than Conventional physical therapy.	1	Yeo et al. 2023
1b	Visual feedback with Unstable surface balance training may produce greater improvements in gait speed than Unstable surface balance training.	1	Yeo et al. 2023
1b	Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not have a	1	Wang et al. 2022c

	difference in efficacy when compared to Sham taping with exercise training for improving gait speed.		
1b	Perturbation treadmill training group may not have a difference in efficacy when compared to Non-perturbation treadmill training group for improving gait speed.	1	Esmaeili et al. 2020
1b	Modified PC Balance Training Gaming Platform may produce greater improvements in gait speed than PC gaming with Mouse.	1	Hsieh et al. 2019b
1b	Video Game-Based Balance Training with conventional physical therapy may not have a difference in efficacy when compared to Conventional physical therapy with Balance Training for improving gait speed.	1	Morone et al. 2014
1b	Standing balance exercises with functional electrical stimulation may not have a difference in efficacy when compared to Usual care for improving gait speed.	1	Kunkel et al. 2013
2	Dual-task balance training may produce greater improvements in gait speed than Single-task balance training.	1	Seo et al. 2012
2	3D balance exercises (3D Thera-Balance) with visual feedback may not have a difference in efficacy when compared to Weight shifting exercises for improving gait speed.	1	Jung et al. 2011
1b	There is conflicting evidence about the effect of Virtual reality-based balance training when compared to Conventional therapy for improving gait speed.	1	Kim et al. 2009

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Non-Supportive Balance Trainers with Feedback may produce greater improvements in gait endurance than Conventional Therapy or Balance Training.	1	Brunelli et al. 2020
1b	Perturbation Balance Trainers with Feedback may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving gait endurance.	1	Thijs et al. 2021
1b	Perturbation Balance Trainers may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving gait endurance.	1	Handelzalts et al. 2019

1a	Standing Practice may not have a difference in efficacy when compared to Conventional Therapy for improving balance.	2	Inoue et al. 2021; Allison et al. 2007
1a	Perturbation Balance Trainers with Feedback may produce greater improvements in balance than Conventional Therapy or Balance Training.	3	An et al. 2021; Jung et al. 2021; Thijs et al. 2021
1a	Perturbation Balance Trainers may not have a difference in efficacy when compared to Conventional Therapy or Balance Training for improving balance.	7	Lanza et al. 2024; Shen et al. 2023; Dusane & Bhatt 2022; Chayasit et al. 2022; Handelzalts et al. 2019; Mansfield et al. 2018; Goljar et al. 2010
2	Visual Deprivation Group Balance Training Group with Conventional Therapy may not have a difference in efficacy when compared to Visual Feedback Balance Training Group with Conventional Therapy for improving balance.	1	Jeong et al. 2024
1b	There is conflicting evidence about the effect of Balance Training with Visual Deprivation when compared to Balance Training with Visual Cues for improving balance.	3	Nam et al. 2022a; Narendra et al. 2013; Yelnik et al. 2008
2	Visual cue deprivation with balance training and head control may produce greater improvements in balance than Visual cue deprivation with Balance training.	1	Nam et al. 2022a
1b	Balance Training with Full Rest Periods may not have a difference in efficacy when compared to Balance Training with Short Rest Periods for improving balance.	1	Elsner et al. 2018

2	Balance Training with Muscle Vibration may not have a difference in efficacy when compared to Conventional Rehabilitation for improving balance.	1	Merkert et al. 2011
1a	Balance Training with Biofeedback may not have a difference in efficacy when compared to Balance Training for improving balance.	3	Martino Cinnera et al. 2024; Lupo et al. 2018; Hung et al. 2017
1a	Vestibular Training may produce greater improvements in balance than Conventional Therapy.	5	Calisgan et al. 2024; Cui et al. 2024; Zhao et al. 2022b; Ekvall Hansson et al. 2020; Tramontano et al. 2018
2	Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may not have a difference in efficacy when compared to gaze stabilization exercises with neurodevelopmental treatment for improving balance.	1	Cui et al. 2024
1a	Robotic Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving balance.	2	Inoue et al. 2022b; De Luca et al. 2020
1b	Trampoline Balance Training may produce greater improvements in balance than Stable Surface Balance Training.	1	Miklitsch et al. 2013
1b	Balance Training with transcutaneous electrical nerve stimulation may produce greater improvements in balance than Balance Training with Conventional Care.	1	Jung et al. 2016
1b	There is conflicting evidence about the effect of Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care when compared to Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care for improving balance.	1	Jung et al. 2016
1b	Balance Training with Shoe Lift may not have a difference in efficacy when compared to Balance Training for improving balance.	1	Sheikh & Hosseini 2021
1a	Strength or Resistance Training with Balance Training may produce greater improvements in balance than Conventional Therapy.	3	Vahlberg et al. 2017a; Vahlberg et al. 2017b; Sekhar et al. 2013
2	Structured Balance Awareness may produce greater improvements in balance than Health Awareness Program.	1	Shaik et al. 2021
2	Balance Training with Fresnel Prism Glasses may produce greater improvements in balance than Balance and Walking Training.	1	Ha & Sung 2020
1b	Sensory Balance Training may not have a difference in efficacy when compared to Robot-assisted Stair Climbing for improving balance.	1	Gandolfi et al. 2019
2	Sitting Balance Training with Sensory Input may produce greater improvements in balance than Sitting Balance.	1	Ibrahimi et al. 2010
1a	Vestibular rehabilitation may not have a difference in efficacy when compared to Convectional treatment for improving balance.	2	Balci et al. 2013; Dai et al. 2013
1b	Progressive Balance Training may produce greater improvements in balance than Balance Training.	1	Memon et al. 2022
1b	Perturbation Balance Training may not have a difference in efficacy when compared to Proprioceptive Neuromuscular Facilitation for improving balance.	1	Adhikari et al. 2024
1b	Visual Scanning Training with Task-Specific Activities may produce greater improvements in balance than Task-Specific Activities Alone.	1	Batool et al. 2022
1b	Cognitive behaviour therapy + task-oriented balance training may produce greater improvements in balance than General health education + task-oriented balance training.	1	Liu et al. 2019
1b	Visual-spatial training exercises using specular vision training, mirror training, and target identification while walking + Conventional rehabilitation may not have a difference in efficacy when compared	1	Tramontano et al. 2019

	to Trunk stabilization and weight transfer exercises + Conventional rehabilitation for improving balance.		
2	Vestibular rehabilitation + conventional PT may not have a difference in efficacy when compared to conventional PT for improving balance.	1	Mitsutake et al. 2017
1b	Pro-Kin system with weight loss system (body-weight support) with balance training may produce greater improvements in balance than Conventional balance training.	1	Lu et al. 2024
1b	Robot assisted gait training with Traditional balance training may not have a difference in efficacy when compared to Traditonal balance training for improving balance.	1	Gunduz et al. 2024
1b	Visual feedback with Unstable surface balance training may produce greater improvements in balance than Conventional physical therapy.	1	Yeo et al. 2023
1b	Visual feedback with Unstable surface balance training may produce greater improvements in balance than Unstable surface balance training.	1	Yeo et al. 2023
1b	Virtual balance training (VBT) with Conservative training may not have a difference in efficacy when compared to Conservative training (traditional rehab techniques) for improving balance.	1	Kilinc et al. 2023
1b	Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not have a difference in efficacy when compared to Sham taping with exercise training for improving balance.	1	Wang et al. 2022c
1b	Visual feedback via Mirror with Verbal feedback and Conventional treatment (static and dynamic balance training) may produce greater improvements in balance than Visual feedback via Mirror with Conventional treatment (static and dynamic balance training).	1	Chaudhary et al. 2022
1b	Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may not have a difference in efficacy when compared to Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy for improving balance.	1	Mihai et al. 2022
1b	Virtual reality balance training with Nintendo Wii with conventional physical therapy may produce greater improvements in balance than Conventional physical therapy.	1	Marques-Sule et al. 2021
1b	Perturbation treadmill training group may produce greater improvements in balance than Non-perturbation treadmill training group.	1	Esmaeili et al. 2020
1b	Balance Training with electromyography- triggered functional electrical stimulation and General Rehabilitation may produce greater improvements in balance than Balance Training without functional electrical stimulation with General Rehabilitation.	1	Lee et al. 2020b
2	Trunk balance training on rocker board with conventional therapy may produce greater improvements in balance than Trunk balance training on plain surface with conventional therapy.	1	Tirupatamma et al. 2019
1b	There is conflicting evidence about the effect of Modified PC Balance Training Gaming Platform when compared to PC gaming with Mouse for improving balance.	1	Hsieh et al. 2019b
1b	Rehabilitation with Balance training and Visual biofeedback may not have a difference in efficacy when compared to rehabilitation program with lateral wedge insole for improving balance.	1	Liao et al. 2018

1b	Wii Fit-based balance exercise with conventional rehabilitation may produce greater improvements in balance than Conventional rehabilitation.	1	Utkan Karasu et al. 2018
1b	Progressive resistance with balance training and motivational session may not have a difference in efficacy when compared to Usual activity for improving balance.	1	Vahlberg et al. 2017a
1b	Virtual reality balance training with treatment may not have a difference in efficacy when compared to treatment for improving balance.	1	Lee et al. 2017d
1b	Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy may produce greater improvements in balance than C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy.	1	Ng et al. 2016
1b	Dynamic balance training with Balance Trainer may produce greater improvements in balance than Static balance training with a conventional standing frame.	1	Braun et al. 2016
1b	Computer-generated interactive visual feedback balance training with Physical therapy may produce greater improvements in balance than Mirror visual feedback balance training with Physical therapy.	1	Yang et al. 2015
2	Balance training with cognitive training may not have a difference in efficacy when compared to Balance training with balance board for improving balance.	1	Choi et al. 2015b
2	Wii-based balance training may not have a difference in efficacy when compared to Progressive balance training for improving balance.	1	Yatar et al. 2015
1b	Contemporary Bobath Concept Approach with early sitting, standing, and walking strategies with balance training may produce greater improvements in balance than Contemporary Bobath Concept Approach.	1	Tang et al. 2014
1b	Video Game-Based Balance Training with conventional physical therapy may produce greater improvements in balance than Conventional physical therapy with Balance Training.	1	Morone et al. 2014
1b	Wii Fit Plus video game (Balance training) may not have a difference in efficacy when compared to Wii Sports video game (Upper limb training) for improving balance.	1	Bower et al. 2014
1b	There is conflicting evidence about the effect of Wii-based balance training when compared to Conventional rehabilitation for improving balance.	2	Barcala et al. 2013; Cho et al. 2012
2	Wii-based balance training may produce greater improvements in balance than Control group.	1	Kim et al. 2012c
1b	Balance training with Balance Control Trainer may produce greater improvements in balance than Conventional rehabilitation.	1	Lee et al. 2012
2	3D balance exercises (3D Thera-Balance) with visual feedback may produce greater improvements in balance than Weight shifting exercises.	1	Jung et al. 2011
1b	Virtual reality-based balance training may produce greater improvements in balance than Conventional therapy.	1	Kim et al. 2009

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Balance-Focused Exercise Programs when compared to Conventional Rehabilitation for improving falls and fear of falling.	1	Tan et al. 2023
1b	Task Specific Balance Training may not have a difference in efficacy when compared to Upper Limb Exercise for improving falls and fear of falling.	1	Pang et al. 2018

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Virtual balance training (VBT) with Conservative training may not have a difference in efficacy when compared to Conservative training (traditional rehab techniques) for improving upper extremity function.	1	Kilinc et al. 2023
1b	Computer-generated interactive visual feedback balance training with Physical therapy may not have a difference in efficacy when compared to Mirror visual feedback balance training with Physical therapy for improving upper extremity function.	1	Yang et al. 2015

Key Points

- Balance-Focused Exercise Programs may be beneficial for improving motor recovery, biomechanical balance measures, functional mobility, and balance, but not sensory and proprioceptive function and activities of daily living, after stroke when compared to Conventional Rehabilitation; the literature is mixed regarding falls and fear of falling.
- Task Specific Balance Training may not be beneficial for improving biomechanical gait measures, activities of daily living, falls and fear of falling, and quality of life after stroke when compared to Upper Limb Exercise; the literature is mixed regarding functional mobility.
- Balance Training with Posture Changes may be beneficial for improving neurophysiological measures, but not activities of daily living, after stroke when compared to Balance Training; the literature is mixed regarding motor recovery and gait speed.

- Shoulder elevation posture change with balance training and Conventional training may be beneficial for improving motor recovery, neurophysiological measures, and gait speed, but not activities of daily living, after stroke when compared to Back posture change with balance training and Conventional training.
- Wobble Board Training may be beneficial for improving biomechanical balance measures, functional mobility, and balance after stroke when compared to Conventional Physiotherapy.
- Balance-Focused Exercise Programs may be beneficial for improving biomechanical balance measures, but not balance and falls and fear of falling, after stroke when compared to At-home Exercises.
- Balance Training Using SMART Balance Master may not be beneficial for improving motor recovery, biomechanical balance measures, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Conventional Rehabilitation.
- Non-Supportive Balance Trainers with Feedback may be beneficial for improving activities of daily living, gait endurance, functional mobility, and balance, but not muscle strength and falls and fear of falling, after stroke when compared to Conventional Therapy or Balance Training; the literature is mixed regarding biomechanical balance measures and sensory and proprioceptive function.
- Balance Training with Visual Biofeedback may be beneficial for improving motor recovery and falls and fear of falling, but not biomechanical gait measures, biomechanical balance measures, spasticity, activities of daily living, functional mobility, and balance, after stroke when compared to Conventional Therapy or Balance Training; the literature is mixed regarding range of motion and gait speed.
- Balance training with self- controlled postural control visual biofeedback may be beneficial for improving biomechanical balance measures after stroke when compared to Balance training with no control over postural control visual biofeedback.
- Standing Practice may be beneficial for improving biomechanical gait measures and functional mobility, but not motor recovery, activities of daily living, and balance, after stroke when compared to Conventional Therapy.
- Perturbation Balance Trainers with Feedback may be beneficial for improving muscle strength and balance, but not spasticity, activities of daily living, gait endurance, and functional mobility, after stroke when compared to Conventional Therapy or Balance Training; the literature is mixed regarding motor recovery and gait speed.
- Perturbation Balance Trainers may be beneficial for improving muscle strength and quality of life, but not biomechanical gait measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, after stroke when compared to Conventional Therapy or Balance Training; the literature is mixed regarding motor recovery, spasticity, and sensory and proprioceptive function.
- Visual Deprivation Group Balance Training Group with Conventional Therapy may be beneficial for improving biomechanical balance measures, but not balance, after stroke when compared to Visual Feedback Balance Training Group with Conventional Therapy.
- Balance Training with Visual Deprivation may be beneficial for improving biomechanical balance measures and activities of daily living, but not biomechanical gait measures, gait speed, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Balance Training with Visual Cues; the literature is mixed regarding balance.
- Visual cue deprivation with balance training and head control may be beneficial for improving balance, but not biomechanical gait measures and biomechanical balance measures, after stroke when compared to Visual cue deprivation with Balance training.
- Balance Training with Kinesthetic Ability Training Device may be beneficial for improving motor recovery and biomechanical balance measures, but not activities of daily living, after stroke when compared to Conventional Rehabilitation.
- Balance Training with Full Rest Periods may not be beneficial for improving balance after stroke when compared to Balance Training with Short Rest Periods.
- Balance Training with Muscle Vibration may not be beneficial for improving functional mobility and balance after stroke when compared to Conventional Rehabilitation; the literature is mixed regarding activities of daily living.
- Balance Training with Biofeedback may be beneficial for improving biomechanical balance measures, gait speed, and quality of life, but not motor recovery, activities of daily living, functional mobility, and balance, after stroke when compared to Balance Training.

- Vestibular Training may be beneficial for improving biomechanical balance measures, gait speed, functional mobility, and balance, but not biomechanical gait measures, muscle strength, activities of daily living, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy.
- Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and functional mobility, but not balance and falls and fear of falling, after stroke when compared to gaze stabilization exercises with neurodevelopmental treatment.
- Robotic Balance Training may be beneficial for improving sensory and proprioceptive function and quality of life, but not motor recovery, biomechanical balance measures, muscle strength, activities of daily living, functional mobility, balance, and falls and fear of falling, after stroke when compared to Conventional Therapy.
- Trampoline Balance Training may be beneficial for improving balance, but not activities of daily living, gait endurance, and functional mobility, after stroke when compared to Stable Surface Balance Training.
- Ankle-Foot orthosis with Balance Training Shoes may be beneficial for improving aerobic measures and gait speed, but not functional mobility, after stroke when compared to Ankle-Foot Orthosis with Regular Shoes.
- Balance Training with transcutaneous electrical nerve stimulation may be beneficial for improving neurophysiological measures and balance after stroke when compared to Balance Training with Conventional Care.
- Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care may be beneficial for improving neurophysiological measures after stroke when compared to Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care; the literature is mixed regarding balance.
- Balance Training with Shoe Lift may be beneficial for improving biomechanical balance measures, but not balance and falls and fear of falling, after stroke when compared to Balance Training.
- Strength or Resistance Training with Balance Training may be beneficial for improving muscle strength, gait speed, gait endurance, and balance, but not motor recovery, neurophysiological measures, activities of daily living, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy.
- Structured Balance Awareness may be beneficial for improving balance and falls and fear of falling after stroke when compared to Health Awareness Program.
- Balance Training with Fresnel Prism Glasses may be beneficial for improving gait speed, gait endurance, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Balance and Walking Training.
- Sensory Balance Training may be beneficial for improving gait endurance, but not biomechanical balance measures, gait speed, functional mobility, and balance, after stroke when compared to Robot-assisted Stair Climbing.
- Sitting Balance Training with Sensory Input may be beneficial for improving functional mobility, balance, and quality of life after stroke when compared to Sitting Balance.
- External focus on balance board task may be beneficial for improving biomechanical balance measures, but not functional mobility, after stroke when compared to Internal focus on balance board task.
- Balance Training may be beneficial for improving gait speed, but not motor recovery, after stroke when compared to No Training; the literature is mixed regarding biomechanical gait measures.
- Vestibular rehabilitation may not be beneficial for improving biomechanical balance measures, activities of daily living, gait speed, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Convectional treatment.
- Progressive Balance Training may be beneficial for improving balance after stroke when compared to Balance Training.
- Perturbation Balance Training may not be beneficial for improving biomechanical gait measures and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation; the literature is mixed regarding functional mobility.

- Class-Based Body Awareness Training may not be beneficial for improving sensory and proprioceptive function, gait speed, and quality of life after stroke when compared to Home-Based Body Awareness Training; the literature is mixed regarding motor recovery.
- Visual Scanning Training with Task-Specific Activities may be beneficial for improving balance, but not activities of daily living, after stroke when compared to Task-Specific Activities Alone.
- Vestibular Training may be beneficial for improving functional mobility and quality of life after stroke when compared to Virtual Reality Training.
- Vestibular rehabilitation therapy + Conventional physical therapy may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Conventional care.
- Cognitive behaviour therapy + task-oriented balance training may be beneficial for improving activities of daily living, balance, and falls and fear of falling after stroke when compared to General health education + task-oriented balance training.
- Visual-spatial training exercises using specular vision training, mirror training, and target identification while walking + Conventional rehabilitation may be beneficial for improving activities of daily living and functional mobility, but not biomechanical balance measures and balance, after stroke when compared to Trunk stabilization and weight transfer exercises + Conventional rehabilitation.
- Vestibular rehabilitation + conventional PT may not be beneficial for improving functional mobility and balance after stroke when compared to conventional PT.
- Pro-Kin system with weight loss system (body-weight support) with balance training may be beneficial for improving functional mobility and balance after stroke when compared to Conventional balance training.
- Metronome training with core strengthening and general balance exercises may be beneficial for improving functional mobility after stroke when compared to Core strengthening with general balance exercises.
- Robot assisted gait training with Traditional balance training may not be beneficial for improving functional mobility, balance, and falls and fear of falling after stroke when compared to Traditonal balance training; the literature is mixed regarding motor recovery.
- Gait-slip perturbation with FES to paretic quadriceps muscle may be beneficial for improving biomechanical gait measures and falls and fear of falling after stroke when compared to Gait-slip perturbations.
- Treadmill gait and balance training with Traditional gait and balance training may not be beneficial for improving gait speed, functional mobility, and falls and fear of falling after stroke when compared to Traditional gait with balance training.
- Visual feedback with Unstable surface balance training may be beneficial for improving gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Conventional physical therapy; the literature is mixed regarding range of motion.
- Visual feedback with Unstable surface balance training may be beneficial for improving gait speed and balance, but not biomechanical gait measures and functional mobility, after stroke when compared to Unstable surface balance training; the literature is mixed regarding range of motion.
- Virtual balance training (VBT) with Conservative training may not be beneficial for improving motor recovery, spasticity, activities of daily living, balance, and quality of life after stroke when compared to Conservative training (traditional rehab techniques).
- The literature is mixed regarding the effect of Foot Mobilization with Intrinsic Foor Muscles Facilitation and (Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations) on biomechanical balance measures after stroke when compared to Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations.
- Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, balance, and falls and fear of falling after stroke when compared to Sham taping with exercise training.
- Visual feedback via Mirror with Verbal feedback and Conventional treatment (static and dynamic balance training) may be beneficial for improving balance after stroke when compared to Visual feedback via Mirror with Conventional treatment (static and dynamic balance training).

- Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may be beneficial for improving motor recovery, biomechanical balance measures, spasticity, and range of motion, but not balance, after stroke when compared to Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy; the literature is mixed regarding functional mobility.
- Virtual reality balance training with Nintendo Wii with conventional physical therapy may be beneficial for improving activities of daily living, functional mobility, and balance, but not motor recovery, after stroke when compared to Conventional physical therapy.
- Perturbation treadmill training group may be beneficial for improving balance, but not muscle strength, activities of daily living, gait speed, and falls and fear of falling, after stroke when compared to Non-perturbation treadmill training group.
- Balance Training with electromyography- triggered functional electrical stimulation and General Rehabilitation may be beneficial for improving neurophysiological measures, functional mobility, and balance after stroke when compared to Balance Training without functional electrical stimulation with General Rehabilitation.
- Trunk balance training on rocker board with conventional therapy may be beneficial for improving gait endurance and balance after stroke when compared to Trunk balance training on plain surface with conventional therapy.
- Modified PC Balance Training Gaming Platform may be beneficial for improving biomechanical balance measures, gait speed, and functional mobility after stroke when compared to PC gaming with Mouse; the literature is mixed regarding balance.
- Rehabilitation with Balance training and Visual biofeedback may not be beneficial for improving functional mobility and balance after stroke when compared to rehabilitation program with lateral wedge insole.
- Wii Fit-based balance exercise with conventional rehabilitation may be beneficial for improving biomechanical balance measures and balance, but not functional mobility, after stroke when compared to Conventional rehabilitation; the literature is mixed regarding activities of daily living.
- Progressive resistance with balance training and motivational session may not be beneficial for improving motor recovery, neurophysiological measures, and balance after stroke when compared to Usual activity; the literature is mixed regarding activities of daily living.
- Virtual reality balance training with treatment may not be beneficial for improving activities of daily living, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to treatment.
- Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy may be beneficial for improving balance, but not gait endurance and quality of life, after stroke when compared to C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy; the literature is mixed regarding functional mobility.
- Tetrax biofeedback balance training with Conventional care may be beneficial for improving sensory and proprioceptive function after stroke when compared to Conventional care; the literature is mixed regarding biomechanical balance measures, muscle strength, and functional mobility.
- Dynamic balance training with Balance Trainer may be beneficial for improving activities of daily living, functional mobility, and balance after stroke when compared to Static balance training with a conventional standing frame.
- Computer-generated interactive visual feedback balance training with Physical therapy may be beneficial for improving motor recovery and balance after stroke when compared to Mirror visual feedback balance training with Physical therapy.
- Balance training with cognitive training may not be beneficial for improving motor recovery, activities of daily living, and balance after stroke when compared to Balance training with balance board.
- Wii-based balance training may not be beneficial for improving activities of daily living, functional mobility, balance, and falls and fear of falling after stroke when compared to Progressive balance training.
- Contemporary Bobath Concept Approach with early sitting, standing, and walking strategies with balance training may be beneficial for improving functional mobility and balance after stroke when compared to Contemporary Bobath Concept Approach.

- Ankle Foot Orthosis (Joint type) with Balance Training may not be beneficial for improving biomechanical balance measures after stroke when compared to No Orthotic with Balance Training; the literature is mixed regarding neurophysiological measures.
- Video Game-Based Balance Training with conventional physical therapy may be beneficial for improving activities of daily living and balance, but not gait speed and functional mobility, after stroke when compared to Conventional physical therapy with Balance Training.
- Wii Fit Plus video game (Balance training) may be beneficial for improving biomechanical balance measures, but not functional mobility, balance, and falls and fear of falling, after stroke when compared to Wii Sports video game (Upper limb training).
- Wii-based balance training may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, and activities of daily living after stroke when compared to Conventional rehabilitation; the literature is mixed regarding functional mobility and balance.
- Standing balance exercises with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Usual care.
- The literature is mixed regarding the effect of Balance training with cognitive training on biomechanical balance measures after stroke when compared to Balance training.
- Dual-task balance training may be beneficial for improving gait speed after stroke when compared to Single-task balance training; the literature is mixed regarding biomechanical balance measures.
- Wii-based balance training may be beneficial for improving functional mobility and balance, but not activities of daily living, after stroke when compared to Control group.
- Balance training with Balance Control Trainer may be beneficial for improving functional mobility and balance, but not muscle strength and activities of daily living, after stroke when compared to Conventional rehabilitation.
- 3D balance exercises (3D Thera-Balance) with visual feedback may be beneficial for improving balance, but not gait speed, after stroke when compared to Weight shifting exercises.
- Virtual reality-based balance training may be beneficial for improving functional mobility and balance, but not biomechanical gait measures and biomechanical balance measures, after stroke when compared to Conventional therapy; the literature is mixed regarding gait speed.
- Visual biofeedback providing posture information may be beneficial for improving biomechanical balance measures after stroke when compared to Standing without biofeedback.
- Pressure sensor-based vibrotactile biofeedback may be beneficial for improving biomechanical balance measures after stroke when compared to Visual biofeedback providing posture information.

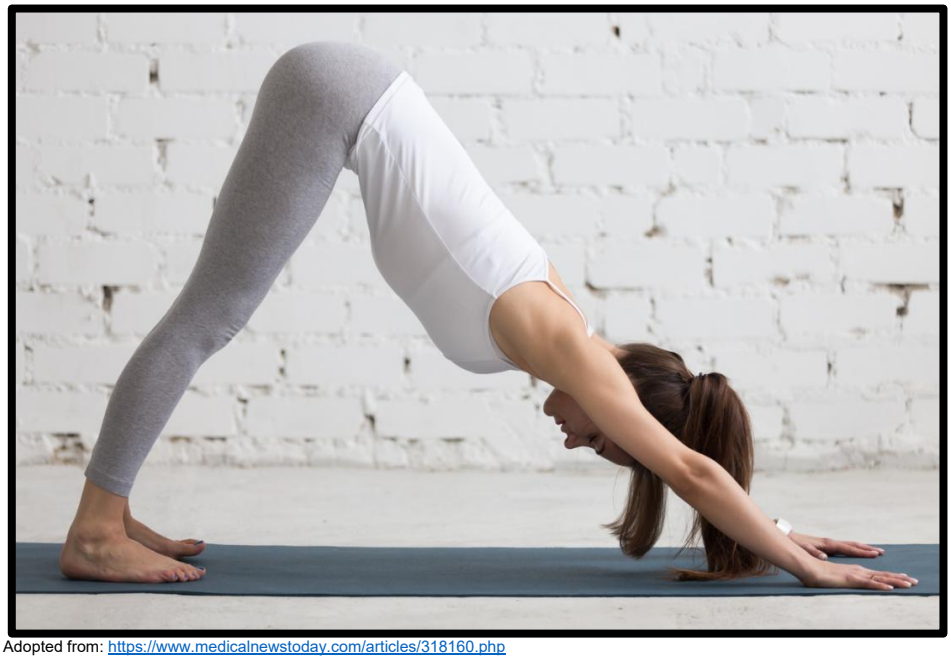
Summary of Key Points: Balance Training

Intervention	Control(s)	Function domain(s)	Effect
Balance-Focused Exercise Programs	Conventional Rehabilitation	Motor recovery, biomechanical balance measures, functional mobility, balance	+
Balance-Focused Exercise Programs	Conventional Rehabilitation	Sensory and proprioceptive function, activities of daily living	–
Balance-Focused Exercise Programs	Conventional Rehabilitation	Falls and fear of falling	=
Task Specific Balance Training	Upper Limb Exercise	Biomechanical gait measures, activities of daily living, falls and fear of falling, quality of life	–
Task Specific Balance Training	Upper Limb Exercise	Functional mobility	=
Balance Training with Posture Changes	Balance Training	Neurophysiological measures	+
Balance Training with Posture Changes	Balance Training	Activities of daily living	–

Balance Training with Posture Changes	Balance Training	Motor recovery, gait speed	=
Shoulder elevation posture change with balance training and Conventional training	Back posture change with balance training and Conventional training	Motor recovery, neurophysiological measures, gait speed	+
Shoulder elevation posture change with balance training and Conventional training	Back posture change with balance training and Conventional training	Activities of daily living	–
Wobble Board Training	Conventional Physiotherapy	Biomechanical balance measures, functional mobility, balance	+
Balance-Focused Exercise Programs	At-home Exercises	Biomechanical balance measures	+
Balance-Focused Exercise Programs	At-home Exercises	Balance, falls and fear of falling	–
Balance Training Using SMART Balance Master	Conventional Rehabilitation	Motor recovery, biomechanical balance measures, activities of daily living, gait speed, functional mobility, balance	–
Non-Supportive Balance Trainers with Feedback	Conventional Therapy or Balance Training	Activities of daily living, gait endurance, functional mobility, balance	+
Non-Supportive Balance Trainers with Feedback	Conventional Therapy or Balance Training	Muscle strength, falls and fear of falling	–
Non-Supportive Balance Trainers with Feedback	Conventional Therapy or Balance Training	Biomechanical balance measures, sensory and proprioceptive function	=
Balance Training with Visual Biofeedback	Conventional Therapy or Balance Training	Motor recovery, falls and fear of falling	+
Balance Training with Visual Biofeedback	Conventional Therapy or Balance Training	Biomechanical gait measures, biomechanical balance measures, spasticity, activities of daily living, functional mobility, balance	–
Balance Training with Visual Biofeedback	Conventional Therapy or Balance Training	Range of motion, gait speed	=
Balance training with self- controlled postural control visual biofeedback	Balance training with no control over postural control visual biofeedback	Biomechanical balance measures	+
Standing Practice	Conventional Therapy	Biomechanical gait measures, functional mobility	+
Standing Practice	Conventional Therapy	Motor recovery, activities of daily living, balance	–
Perturbation Balance Trainers with Feedback	Conventional Therapy or Balance Training	Muscle strength, balance	+
Perturbation Balance Trainers with Feedback	Conventional Therapy or Balance Training	Spasticity, activities of daily living, gait endurance, functional mobility	–
Perturbation Balance Trainers with Feedback	Conventional Therapy or Balance Training	Motor recovery, gait speed	=
Perturbation Balance Trainers	Conventional Therapy or Balance Training	Muscle strength, quality of life	+
Perturbation Balance Trainers	Conventional Therapy or Balance Training	Biomechanical gait measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling	–
Perturbation Balance Trainers	Conventional Therapy or Balance Training	Motor recovery, spasticity, sensory and proprioceptive function	=

Visual Deprivation Group Balance Training Group with Conventional Therapy	Visual Feedback Balance Training Group with Conventional Therapy	Biomechanical balance measures	+
Visual Deprivation Group Balance Training Group with Conventional Therapy	Visual Feedback Balance Training Group with Conventional Therapy	Balance	–
Balance Training with Visual Deprivation	Balance Training with Visual Cues	Biomechanical balance measures, activities of daily living	+
Balance Training with Visual Deprivation	Balance Training with Visual Cues	Biomechanical gait measures, gait speed, functional mobility, falls and fear of falling, quality of life	–
Balance Training with Visual Deprivation	Balance Training with Visual Cues	Balance	=
Visual cue deprivation with balance training and head control	Visual cue deprivation with Balance training	Balance	+
Visual cue deprivation with balance training and head control	Visual cue deprivation with Balance training	Biomechanical gait measures, biomechanical balance measures	–
Balance Training with Kinesthetic Ability Training Device	Conventional Rehabilitation	Motor recovery, biomechanical balance measures	+
Balance Training with Kinesthetic Ability Training Device	Conventional Rehabilitation	Activities of daily living	–
Balance Training with Full Rest Periods	Balance Training with Short Rest Periods	Balance	–
Balance Training with Muscle Vibration	Conventional Rehabilitation	Functional mobility, balance	–
Balance Training with Muscle Vibration	Conventional Rehabilitation	Activities of daily living	=
Balance Training with Biofeedback	Balance Training	Biomechanical balance measures, gait speed, quality of life	+
Balance Training with Biofeedback	Balance Training	Motor recovery, activities of daily living, functional mobility, balance	–
Vestibular Training	Conventional Therapy	Biomechanical balance measures, gait speed, functional mobility, balance	+
Vestibular Training	Conventional Therapy	Biomechanical gait measures, muscle strength, activities of daily living, falls and fear of falling, quality of life	–
Gaze stabilization exercises with balance exercises and neurodevelopmental treatment	gaze stabilization exercises with neurodevelopmental treatment	Biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility	+
Gaze stabilization exercises with balance exercises and neurodevelopmental treatment	gaze stabilization exercises with neurodevelopmental treatment	Balance, falls and fear of falling	–
Robotic Balance Training	Conventional Therapy	Sensory and proprioceptive function, quality of life	+
Robotic Balance Training	Conventional Therapy	Motor recovery, biomechanical balance measures, muscle strength, activities of daily living, functional mobility, balance, falls and fear of falling	–
Trampoline Balance Training	Stable Surface Balance Training	Balance	+
Trampoline Balance Training	Stable Surface Balance Training	Activities of daily living, gait endurance, functional mobility	–

Ankle-Foot orthosis with Balance Training Shoes	Ankle-Foot Orthosis with Regular Shoes	Aerobic measures, gait speed	+
Ankle-Foot orthosis with Balance Training Shoes	Ankle-Foot Orthosis with Regular Shoes	Functional mobility	–
Balance Training with transcutaneous electrical nerve stimulation	Balance Training with Conventional Care	Neurophysiological measures, balance	+
Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care	Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care	Neurophysiological measures	+
Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care	Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care	Balance	=
Balance Training with Shoe Lift	Balance Training	Biomechanical balance measures	+
Balance Training with Shoe Lift	Balance Training	Balance, falls and fear of falling	–
Strength or Resistance Training with Balance Training	Conventional Therapy	Muscle strength, gait speed, gait endurance, balance	+
Strength or Resistance Training with Balance Training	Conventional Therapy	Motor recovery, neurophysiological measures, activities of daily living, functional mobility, falls and fear of falling, quality of life	–
Structured Balance Awareness	Health Awareness Program	Balance, falls and fear of falling	+
Balance Training with Fresnel Prism Glasses	Balance and Walking Training	Gait speed, gait endurance, functional mobility, balance	+
Balance Training with Fresnel Prism Glasses	Balance and Walking Training	Biomechanical gait measures	–
Sensory Balance Training	Robot-assisted Stair Climbing	Gait endurance	+
Sensory Balance Training	Robot-assisted Stair Climbing	Biomechanical balance measures, gait speed, functional mobility, balance	–
Sitting Balance Training with Sensory Input	Sitting Balance	Functional mobility, balance, quality of life	+
External focus on balance board task	Internal focus on balance board task	Biomechanical balance measures	+
External focus on balance board task	Internal focus on balance board task	Functional mobility	–
Balance Training	No Training	Gait speed	+
Balance Training	No Training	Motor recovery	–
Balance Training	No Training	Biomechanical gait measures	=
Vestibular rehabilitation	Convectional treatment	Biomechanical balance measures, activities of daily living, gait speed, functional mobility, balance, falls and fear of falling, quality of life	–
Progressive Balance Training	Balance Training	Balance	+



Perturbation Balance Training	Proprioceptive Neuromuscular Facilitation	Biomechanical gait measures, balance	–
Perturbation Balance Training	Proprioceptive Neuromuscular Facilitation	Functional mobility	=
Class-Based Body Awareness Training	Home-Based Body Awareness Training	Sensory and proprioceptive function, gait speed, quality of life	–
Class-Based Body Awareness Training	Home-Based Body Awareness Training	Motor recovery	=
Visual Scanning Training with Task-Specific Activities	Task-Specific Activities Alone	Balance	+
Visual Scanning Training with Task-Specific Activities	Task-Specific Activities Alone	Activities of daily living	–
Vestibular Training	Virtual Reality Training	Functional mobility, quality of life	+
Vestibular rehabilitation therapy + Conventional physical therapy	Conventional care	Biomechanical gait measures, gait speed	–
Cognitive behaviour therapy + task-oriented balance training	General health education + task-oriented balance training	Activities of daily living, balance, falls and fear of falling	+
Visual-spatial training exercises using specular vision training, mirror training, and target identification while walking + Conventional rehabilitation	Trunk stabilization and weight transfer exercises + Conventional rehabilitation	Activities of daily living, functional mobility	+
Visual-spatial training exercises using specular vision training, mirror training, and target identification while walking + Conventional rehabilitation	Trunk stabilization and weight transfer exercises + Conventional rehabilitation	Biomechanical balance measures, balance	–
Vestibular rehabilitation + conventional PT	conventional PT	Functional mobility, balance	–
Pro-Kin system with weight loss system (body-weight support) with balance training	Conventional balance training	Functional mobility, balance	+
Metronome training with core strengthening and general balance exercises	Core strengthening with general balance exercises	Functional mobility	+
Robot assisted gait training with Traditional balance training	Traditonal balance training	Functional mobility, balance, falls and fear of falling	–
Robot assisted gait training with Traditional balance training	Traditonal balance training	Motor recovery	=
Gait-slip perturbation with FES to paretic quadriceps muscle	Gait-slip perturbations	Biomechanical gait measures, falls and fear of falling	+
Treadmill gait and balance training with Traditional gait and balance training	Traditional gait with balance training	Gait speed, functional mobility, falls and fear of falling	–
Visual feedback with Unstable surface balance training	Conventional physical therapy	Gait speed, functional mobility, balance	+
Visual feedback with Unstable surface balance training	Conventional physical therapy	Biomechanical gait measures	–
Visual feedback with Unstable surface balance training	Unstable surface balance training	Gait speed, balance	+
Visual feedback with Unstable surface balance training	Unstable surface balance training	Biomechanical gait measures, functional mobility	–

Visual feedback with Unstable surface balance training	Unstable surface balance training	Range of motion	=
Visual feedback with Unstable surface balance training	Conventional physical therapy	Range of motion	=
Virtual balance training (VBT) with Conservative training	Conservative training (traditional rehab techniques)	Motor recovery, spasticity, activities of daily living, balance, quality of life	–
Foot Mobilization with Intrinsic Foor Muscles Facilitation and (Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations)	Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations	Biomechanical balance measures	=
Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training)	Sham taping with exercise training	Biomechanical gait measures, gait speed, gait endurance, balance, falls and fear of falling	–
Visual feedback via Mirror with Verbal feedback and Conventional treatment (static and dynamic balance training)	Visual feedback via Mirror with Conventional treatment (static and dynamic balance training)	Balance	+
Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Motor recovery, biomechanical balance measures, spasticity, range of motion	+
Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Balance	–
Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Functional mobility	=
Virtual reality balance training with Nintendo Wii with conventional physical therapy	Conventional physical therapy	Activities of daily living, functional mobility, balance	+
Virtual reality balance training with Nintendo Wii with conventional physical therapy	Conventional physical therapy	Motor recovery	–
Perturbation treadmill training group	Non-perturbation treadmill training group	Balance	+
Perturbation treadmill training group	Non-perturbation treadmill training group	Muscle strength, activities of daily living, gait speed, falls and fear of falling	–
Balance Training with electromyography- triggered functional electrical stimulation and General Rehabilitation	Balance Training without functional electrical stimulation with General Rehabilitation	Neurophysiological measures, functional mobility, balance	+
Trunk balance training on rocker board with conventional therapy	Trunk balance training on plain surface with conventional therapy	Gait endurance, balance	+
Modified PC Balance Training Gaming Platform	PC gaming with Mouse	Biomechanical balance measures, gait speed, functional mobility	+
Modified PC Balance Training Gaming Platform	PC gaming with Mouse	Balance	=
Rehabilitation with Balance training and Visual biofeedback	rehabilitation program with lateral wedge insole	Functional mobility, balance	–

Wii Fit-based balance exercise with conventional rehabilitation	Conventional rehabilitation	Biomechanical balance measures, balance	+
Wii Fit-based balance exercise with conventional rehabilitation	Conventional rehabilitation	Functional mobility	–
Wii Fit-based balance exercise with conventional rehabilitation	Conventional rehabilitation	Activities of daily living	=
Progressive resistance with balance training and motivational session	Usual activity	Motor recovery, neurophysiological measures, balance	–
Progressive resistance with balance training and motivational session	Usual activity	Activities of daily living	=
Virtual reality balance training with treatment	treatment	Activities of daily living, functional mobility, balance, falls and fear of falling, quality of life	–
Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy	Balance	+
Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy	Gait endurance, quality of life	–
Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy	Functional mobility	=
Tetrax biofeedback balance training with Conventional care	Conventional care	Sensory and proprioceptive function	+
Tetrax biofeedback balance training with Conventional care	Conventional care	Biomechanical balance measures, muscle strength, functional mobility	=
Dynamic balance training with Balance Trainer	Static balance training with a conventional standing frame	Activities of daily living, functional mobility, balance	+
Computer-generated interactive visual feedback balance training with Physical therapy	Mirror visual feedback balance training with Physical therapy	Motor recovery, balance	+
Balance training with cognitive training	Balance training with balance board	Motor recovery, activities of daily living, balance	–
Wii-based balance training	Progressive balance training	Activities of daily living, functional mobility, balance, falls and fear of falling	–
Contemporary Bobath Concept Approach with early sitting, standing, and walking strategies with balance training	Contemporary Bobath Concept Approach	Functional mobility, balance	+
Ankle Foot Orthosis (Joint type) with Balance Training	No Orthotic with Balance Training	Biomechanical balance measures	–
Ankle Foot Orthosis (Joint type) with Balance Training	No Orthotic with Balance Training	Neurophysiological measures	=
Video Game-Based Balance Training with conventional physical therapy	Conventional physical therapy with Balance Training	Activities of daily living, balance	+
Video Game-Based Balance Training with conventional physical therapy	Conventional physical therapy with Balance Training	Gait speed, functional mobility	–

Wii Fit Plus video game (Balance training)	Wii Sports video game (Upper limb training)	Biomechanical balance measures	+
Wii Fit Plus video game (Balance training)	Wii Sports video game (Upper limb training)	Functional mobility, balance, falls and fear of falling	−
Wii-based balance training	Conventional rehabilitation	Biomechanical gait measures, biomechanical balance measures, activities of daily living	−
Standing balance exercises with functional electrical stimulation	Usual care	Biomechanical gait measures, gait speed, functional mobility	−
Balance training with cognitive training	Balance training	Biomechanical balance measures	=
Dual-task balance training	Single-task balance training	Gait speed	+
Dual-task balance training	Single-task balance training	Biomechanical balance measures	=
Wii-based balance training	Conventional rehabilitation	Biomechanical balance measures	−
Wii-based balance training	Control group	Functional mobility, balance	+
Wii-based balance training	Control group	Activities of daily living	−
Balance training with Balance Control Trainer	Conventional rehabilitation	Functional mobility, balance	+
Balance training with Balance Control Trainer	Conventional rehabilitation	Muscle strength, activities of daily living	−
3D balance exercises (3D Thera-Balance) with visual feedback	Weight shifting exercises	Balance	+
3D balance exercises (3D Thera-Balance) with visual feedback	Weight shifting exercises	Gait speed	−
Virtual reality-based balance training	Conventional therapy	Functional mobility, balance	+
Virtual reality-based balance training	Conventional therapy	Biomechanical gait measures, biomechanical balance measures	−
Virtual reality-based balance training	Conventional therapy	Gait speed	=
Visual biofeedback providing posture information	Standing without biofeedback	Biomechanical balance measures	+
Pressure sensor-based vibrotactile biofeedback	Visual biofeedback providing posture information	Biomechanical balance measures	+
Wii-based balance training	Conventional rehabilitation	Functional mobility, balance	=

Stretching or Mobilization Exercises

Adopted from: https://www.medicalnewstoday.com/articles/318160.php

Stretching exercise performed during dynamic activities such as pilates, yoga, and tai chi or during proprioceptive neuromuscular facilitation aims to reduce hypertonicity post-stroke. Prevention of hypertonicity may reduce the risk for development of contracture while improving the range of motion of the joint and stability of the whole-body. Most stretching activities are of relatively low physical impact and low cost. From a fitness standpoint, they focus on flexibility, balance, coordination and muscle endurance (Donahoe-Fillmore & Grant, 2019). Given these attributes, dynamic stretching could provide an alternative therapy to improve lower extremity rehabilitation. In addition, these practices have non-physical benefits. It has been reported that yoga can increase mental health outcomes and contribute to a higher overall quality of life (Büssing et al., 2012). Stretching activities are also benefiting from the addition of technology as evidenced by the use of VR and ankle stretching robotics.

A total of 53 RCTs were found that evaluated stretching or mobilization exercises for lower extremity motor rehabilitation. Two RCTs compared Functional Stretching with Conventional Therapy (Pradines et al. 2019; Ghasemi et al. 2018). Thirteen RCTs compared Mobilization Therapy or Placebo with Conventional Therapy or Placebo (Li et al. 2024b; Traxler et al. 2024; Dengiz et al. 2024; Kim et al. 2024c; Arabzadeh et al. 2023; Lee et al. 2023b; Choi et al. 2023; Longo et al. 2023; Park et al. 2022; Navid et al. 2022; Midan et al. 2022; Kim & Lee 2018a; An et al. 2017). Two RCTs compared Early and Intense Mobilization with Standard Care (Anjos et al. 2023; Bernhardt et al. 2008). One RCT compared Active Stretching with Joint Mobilization (Cho et al. 2020c). Two RCTs compared Mobilization With Movement with Muscle Stretching (Park et al. 2020b; Park et al. 2019a). One RCT compared Mobilization With with Without Incline Board (Park et al. 2018b). Twelve RCTs compared Dynamic Stretching (Tai Chi, Yoga, Pilates) with Conventional or No Therapy (Garcia-Bravo et al. 2024; Haolin et al. 2024; Lenoir Dit Caron et al. 2024; Zhao et al. 2022a; Song et al. 2021a; Chan & Tsang 2018; Chan & Tsang 2017b; Lim et al. 2016; Kim et al. 2015d; Immink et al. 2014; Schmid et al. 2012; Au-Yeung et al. 2009). One RCT compared Dynamic Stretching with SilverSneaker exercises vs Usual care (Taylor-Piliae et al. 2014). Two RCTs compared Body Weight Supported Dynamic Stretching with Conventional Therapy (Yu et al. 2020a; Huang et al. 2019). One RCT compared Early Proprioceptive Neuromuscular Facilitation (PNF) with late Proprioceptive Neuromuscular Facilitation (PNF) (Morreale et al. 2016). One RCT compared Baduanjin Training with Conventional Exercise (Yuen et al. 2021). Two RCTs compared Proprioceptive Neuromuscular Facilitation (PNF) with Conventional Therapy (Rostami et al. 2024; Asghar et al. 2021). One RCT compared Proprioceptive Neuromuscular Facilitation (PNF) with Custom Exercises with Custom Exercises Alone (Stern et al. 1970). One RCT compared Proprioceptive Neuromuscular Facilitation (PNF) with VR with PNF or VR Alone (dos Santos Junior et al. 2019). One RCT compared Proprioceptive Neuromuscular Facilitation (PNF) with Electrical Stimulation with PNF Alone (Shim et al., 2020). One RCT compared Technology-Assisted Ankle Stretcher with Stretching Board (Yoo et al. 2018a). One RCT evaluated Isotonic and Isokinetic Stretch (Maynard et al. 2005). One RCT compared Ankle Range of Motion Training with No Treatment (Rydwik et al. 2006). One RCT compared Stretching in a Supine Position with Stretching in a Seated Position (Fleuren et al. 2006). One RCT compared PNF-Based Gait Training with

Conventional Gait Training (Asghar et al. 2023). One RCT evaluated Comparison of Joint Mobilization Techniques (Buyukturan et al. 2022). One RCT compared Peripheral Nerve Mobilization with VR-Based Gait Training with Conventional Exercises (Vishnuram et al. 2024).

In addition, 21 RCTs in which stretching or mobilization exercises formed part of a combined or comparative intervention are cross-referenced at the end of Table 12; their primary listings appear in other tables.

The methodological details and results of all 53 RCTs are presented in Table 12.

Table 12. RCTs Evaluating Stretching or Mobilization Exercises for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Functional Stretching vs Conventional Therapy		
Pradines et al. (2019) RCT (6) Nstart=23 Nend=23 TPS=Chronic A vs 0	E: Guided Self-rehabilitation Stretching Program C: Conventional Care Duration: 0-3d/wk, 52 wks conventional PT 24.7min/d, 7d/wk, 52wks self-stretch	E vs C: Muscle architecture Fascicle length in soleus muscle (+exp) Soleus thickness (+exp) Medial gastrocnemius thickness (+exp) Tardieu scale-passive extensibility Soleus (+exp) Gastrocnemius (+exp) Gluteus maximus (-) Rectus femoris (+exp) 10m Walk test (+exp)
Ghasemi et al. (2018) RCT (5) Nstart=45 Nend=45 TPS=Chronic A vs 0	E: Functional stretch training C: Conventional physiotherapy Duration: 5min/d, 3d/wk, 4wks	E vs C: H-reflex latency (-) Hmax/Mmax Ratio (-) Ultrasonic measurement Fasicle length (-) pennation angle (-) muscle thickness (-) Modified Ashworth Scale (No stats) Achilles Deep Tendon Reflex (No stats) Active Range of Motion: Ankle (No stats) Ankle clonus (No stats)
Mobilization vs Conventional Therapy or Placebo		
Li et al. (2024b) RCT (4) Nstart=40 Nend=40 TPS=Subacute A vs 0	E: Fascial manipulation therapy + Conventional therapy C: Conventional therapy Duration: Fascial manipulation therapy (30 mins/d, 2ds/wk, 3wks); Conventional therapy (40 mins, 5ds/wk, 3wks)	E vs C: Comprehensive spasticity scale (+exp) Passive range of motion (+exp) FMA-LE (+exp) Modified ashworth scale (+exp)
Traxler et al. (2024) Feasibility/pilot RCT (8) Nstart=36 Nend=36 TPS=Chronic A + B + C vs B + C vs 0	E1: Manual therapy + task oriented training + home exercise program, E2: task oriented training + home exercise program C: conventional rehab Duration: Clinic: 45min/d, 2d/wk, 4wks Home: 20min/d, 4d/wk, 4wks	E1 vs E2: MiniBestest(-) TUG(-) 10MWT(-) Active Ankle ROM(+exp1) Passive Ankle ROM(+exp1) SIS

Also in Table 5 (Task-Specific Training)		Strength(-) ADL(-) mobility(-) social participation(-) overall recovery(-) E1 vs C: MiniBestest(+exp1) TUG(+exp1) 10MWT(-) Active Ankle ROM(+exp1) Passive Ankle ROM(+exp1) SIS Strength(+exp1) ADL(+exp1) mobility(+exp1) social participation(+exp1) overall recovery(+exp1) E2 vs C: MiniBestest(+exp2) TUG(+exp2) 10MWT(-) Active Ankle ROM(+exp2) Passive Ankle ROM(-) SIS Strength(+exp2) ADL(-) mobility(+exp2) social participation(-) overall recovery(+exp2)
Dengiz et al. (2024) RCT (5) Nstart=27 Nend=24 TPS=Chronic A + B vs B Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)	E: Cervical mobilization + Bobath neurodevelopmental therapy C: Sham spinal mobilization + Bobath neurodevelopmental therapy Duration: 75min (60min BT + 15min mobilization)/d, 3d/wk, 4wks	E vs C: Craniovertebral angle (-) Balance left side (-) right side (+exp) forward (+exp) backward (+exp) total balance (+exp) Gait parameters stride number (+exp) stride length (+exp) stride time (+exp) stride velocity (+exp) cadence (+exp) double support time (-) TUG (+exp)
Kim et al. (2024c) RCT (7) Nstart=50 Nend=50 TPS=Chronic A + B vs C + B vs B Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)	E1: Sustained natural apophyseal glides + neurodevelopmental techniques E2: Maitland mobilization + neurodevelopmental techniques C: conventional rehab + neurodevelopmental techniques Duration: less than 10 mins, 5d/wk, 4wks	E1 vs E2: Postural sway(-) FTSST(-) FRT(-) 10MWT(-) 6MWT(-)

Arabzadeh et al. (2023) RCT (6) Nstart=20 Nend=20 TPS=Chronic A vs 0	E: Hip mobilization C: Conventional rehab Duration: 60min/d(30min conventional, 30min Hip mobilization), 3d/wk, 4wks	E vs C: BBS(+exp) TUG(+exp) static postural control (+exp) antroposterior (+exp) mediolateral (-) dynamic postural control (-) antroposterior (+exp) mediolateral (+exp) EMG muscle activation biceps femoris (+exp) medial gastrocnemius (-) rectus femoris (+exp) tibialis anterior (-) rectus abdominus (-) erector spine (-)
Lee et al. (2023b) RCT (6) Nstart=69 Nend=69 TPS=Chronic A + B vs A vs 0 Also in Table 53 (Acupuncture and Massage)	E1: Joint mobilization + acupuncture E2: Joint mobilization C: Conventional rehab Duration: 60min/d(30min conventional, 30min acupuncture), 2d/wk, 12wks	E1 vs E2: Pain-VAS(-) SPADI(+exp1) WOMAC(-) AROM Shoulder flexion(-) Shoulder abduction(-) Shoulder adduction(-) knee flexion(-) 10MWT(-) FGA(-) MFT(+exp1) ADL(-) IADL(+exp1) CES-D(-) BDI(-) E1 vs C: Pain-VAS(-) SPADI(+exp1) WOMAC(+exp1) AROM Shoulder flexion(-) Shoulder abduction(-) Shoulder adduction(-) knee flexion(+exp1) 10MWT(-) FGA(-) MFT(+exp1) ADL(+exp1) IADL(+exp1) CES-D(+exp1) BDI(+exp1) E2 vs C: Pain-VAS(-) SPADI(+exp2) WOMAC(-) AROM Shoulder flexion(-)

		Shoulder abduction(-) Shoulder adduction(-) knee flexion(+exp2) 10MWT(-) FGA(-) MFT(+exp2) ADL(+exp2) IADL(-) CES-D(+exp2) BDI(+exp2)
Choi et al. (2023) Feasibility/pilot RCT (6) Nstart=30 Nend=30 TPS=Chronic A vs 0	E: Lumbar Joint mobilization C: Sham Lumbar Joint mobilization Duration: 15min/d, 5d/wk, 6wks	E vs C: TIS Static(-) dynamic(-) coordination(+exp) Total(+exp) Body weight disturbance(+exp) BBS(+exp) TUG(+exp) 10MWT(+exp) FGA(+exp) Step length(+exp) Stride length(+exp)
Longo et al. (2023) Feasibility/pilot RCT (6) Nstart=10 Nend=10 TPS=Chronic A vs 0	E: Muscle shortening maneuver C: Conventional rehab Duration: 1hr/d, 1d/wk, 4wks	E vs C: MAS(-) MI(-) Tonic Stretch Reflex Threshold (TSRT)(+exp) Dorsiflex strength(+exp) BI(-) TUG(+exp) AROM(+exp) PROM(-)
Park et al. (2022) RCT (4) Nstart=42 Nend=42 TPS=Chronic A1 vs A2	E: Grade III lumbar mobilization C: Grade I Lumbar rotational mobilization Duration: 1 min/ session, 6 sessions	E vs C: TIS static sitting balance (-) dynamic sitting balance (+exp) coordination (+exp) total (+exp) Cadence (+exp) gait speed (+exp) stride length (+exp) gait cycle symmetric index (+exp) Pelvic angle tilt symmetric index (+exp) pelvic angle obliquity symmetric index (+exp) Pelvic angle rotation symmetric index (+exp)
Navid et al. (2022) RCT (7) Nstart=29 Nend=29 TPS=Chronic	E: High-velocity, low amplitude (HVLA) chiropractic spinal adjustments C: Passive movement Duration: 15min, 1 session	E vs C: MEP Amplitude Absolute (+exp) Relative (+exp)

A vs B		
Midan et al. (2022) RCT (6) Nstart=30 Nend=30 TPS=Chronic A + B vs C Also in Table 11 (Balance Training); Table 21 (Strength and Resistance Training)	E: Foot Mobilization + Intrinsic Foor Muscles Facilitation + (Strength and Resistance training including PNF, Gait training and Balance training through Pertubations) C: Strength and Resistance training including PNF, Gait training and Balance training through Pertubations Duration: 60 min/session, 3 session/wk, 4 wks	E vs C: Center of Pressure Mediolaterl displacement (-) Mediolateral Speed (-) Mediolateral width (-) Anteroposterior speed (+exp) Anteroposterior displacement (+exp) Reverse Anteroposterior displacement (+exp)

(2018) RCT (6) Nstart=22 Nend=21 TPS=Chronic A vs 0 Primary listing: Table 31 (Muscle Vibration)	E: Whole Body Vibration (40 hz,4 mm) + Exercise (Stretching and active ROM exercise) C: Sham Vibration + Exercise (Stretching and active ROM exercise) Duration: 15min, 3d/wk, for 4wks Exercise & 5min, 3d/wk, for 4wks WBV/Sham	E vs C: 10-meter Walk Test (+exp) Functional Independence Measurement (-) Modified Ashworth Scale-Ankle (-)
Taheri et al. (2017) RCT (5) Nstart=28 Nend=25 TPS=Subacute A + B vs B Primary listing: Table 35 (Extracorporeal Shockwave Therapy and Therapeutic Ultrasound)	E: Extracorporeal Shock Wave Therapy + Standard stretching + Oral anti-spastic drugs C: Standard stretching + Oral anti-spastic drugs Duration: 1x/wk for 3wks Extracorporeal shock wave therapy; 30min/d, 5x/wk, for 3wks Standard Stretching; 2mg/d for 4d then 4mg/d, for 3wks oral anti-spastic	E vs C: passive ROM (-) Clonus score (-) 3m Walk test (-) Lower extremity Functional Score (-) Visual Analogue scale-pain (-) Modified Ashworth scale (-)
Krukowska et al. (2016) RCT (4) Nstart=72	E1: Neurodevelopmental BCA E2: PNF method (proprioceptive neuromuscular facilitation)	E1 vs E2: Gait Parameters Total area of support (+exp1)

Nend=72 TPS=Subacute A vs B Primary listing: Table 1 (Neurodevelopmental Techniques and Motor Relearning)	Duration 6d/wk, for 6wks (35 sessions total)	Center of Pressure pathway length (+exp1)
Kim et al. (2015f) RCT (4) Nstart=20 Nend=20 TPS=Chronic A vs B Primary listing: Table 20 (Aquatic Therapy)	E: Aquatic therapy (based on proprioceptive neuromuscular facilitation) C: Proprioceptive neuromuscular facilitation on the ground Duration: 30min/d, 5d/wk for 6wks	E vs C: Berg Balance Scale (+exp) Timed Up and Go Test (+exp) Functional Reach Test (+exp) One Leg Stand Test (+exp) Functional Independence Measure (+exp)
Kim et al. (2015b) RCT (4) Nstart=20 Nend=20 TPS=Chronic A vs 0 Primary listing: Table 20 (Aquatic Therapy)	E: Aquatic therapy (based on proprioceptive neuromuscular facilitation) C: Conventional therapy Duration: 30min/d, 5d/wk for 6wks conventional rehabilitation for both groups	E vs C: Berg Balance Scale (+exp) Functional Reach Test (+exp) 10-Meter Walk Test (+exp) Timed Up and Go Test (+exp)
Forrester et al. (2014) RCT (5) Nstart=39 Nend=34 TPS=Acute A vs B Primary listing: Table 27 (Electromechanical and Robotic Devices)	E: Performance-based training with Anklebot stretching C: Manual stretching of ankle Duration: Performance Based Training: 60min, daily Duration not specified	E vs C: 8 m Walk (-) Berg Balance Scale (-) AROM (-) Muscle strength (-) Functional Independence Measure (-) Interlimb temporal symmetry (+exp) Step time ratio (+exp) Interlimb spatial symmetry (+exp) Step length ratio (-) Peak angular velocity (+exp) Mean angular velocity (-) Movement smoothness Normalized jerk (+exp) Target success (+exp) Step time Paretic (-) Non paretic (-) Step time symmetry (+exp) Step length Paretic (-) Non paretic (-) Step length symmetry (+exp)
Chiong et al. (2013) RCT (8) Nstart=9 Nend=8 TPS=Chronic A + B vs C Primary listing: Table 13 (Orthotic Devices)	E: Stretching exercise + wearing toe spreader C: No Orthotic (conventional care) Duration: Daily stretching exercise & wearing spreader over 6mo	E vs C: Gait velocity (-) Stride length (-) Step length (-) Modified Ashworth scale (-) Berg Balance scale (-) Cadence (-) plantar surface contact area (-)

Waldman et al. (2013) RCT (5) Nstart=24 Nend=23 TPS=Chronic A vs B Primary listing: Table 27 (Electromechanical and Robotic Devices)	E: Robot assisted passive stretching and active movement training C: At-home passive ankle stretching Duration: 60min/d, 3d/wk for 6wks	E vs C: Modified Ashworth Scale (+exp) Stroke Rehabilitation Assessment of Movement (+exp) Berg Balance Scale (+exp) 6 minute Walk Test (-) Ankle Dorsiflexion Passive Range of Motion (+exp) Ankle Dorsiflexion Active Range of Motion (-) Isometric Muscle Strength (+exp) Maximal Voluntary Contraction (+exp) Vertical Ground Reaction during Stance Phase (+exp)
Sahin et al. (2011) RCT (6) Nstart=46 Nend=41 TPS=Chronic A + B vs B Primary listing: Table 35 (Extracorporeal Shockwave Therapy and Therapeutic Ultrasound)	E: Therapeutic ultrasound + passive stretching exercise C: Passive stretching exercise Duration: 5d/wk, for 4wks stretching exercise & 10min/d, 5d/wk, for 4wks ultrasound	E vs C: Modified Ashworth scale(-) Ankle dorsiflexion ROM (active/passive) (-) Brunnstrom Motor Recovery Stage (lower) (-) Functional Independency Measure (-) MAS, Hmax/Mmax ratio (-)
Carda et al. (2011) RCT (7) Nstart=69 Nend=67 TPS=Chronic A + B + C vs A + D + C vs A + C Primary listing: Table 46 (Botulinum Toxin)	E1: Botulinum toxin A (100U) + Serial casting + stretching and gait training E2: Botulinum toxin A (100U) + Taping + stretching and gait training E3: Botulinum toxin A (100U) + stretching and gait training Duration: 1wk of serial casting, or 5d of taping, or 30 min, 2sessions/d, 1wk of stretching, then 30min gait training + 20 min stretching, 1session/d, 1wk.	E1 vs E2: Modified Ashworth Scale (+exp1) 6min walking test (-) 10-meter walk test (-) Functional Ambulation category (-) Strength of ankle dorsal flexors (-) Passive range of motion- ankle (+exp1)
Kluding et al. (2008) RCT (5) Nstart=17 Nend=16 TPS=Chronic A + B vs A Primary listing: Table 5 (Task-Specific Training)	E: Task-specific training + Ankle joint mobilizations C: Task-specific training Duration: 30min/d, 2d/wk for 4wk	E vs C: Passive ROM (+exp) Active ROM (+exp) Ankle Kinematics (-); -during sit-to-stand (-); during Gait (-) Weight bearing symmetry; -during static standing (-); - during sit-to-stand (+con) Sit-to-Stand time (+exp) Rivermead mobility index (-)
Baricich et al. (2008) RCT (6) Nstart=23 Nend=23 TPS=Chronic A + B vs A + C vs A + D Primary listing: Table 46 (Botulinum Toxin)	E1: Botulinum toxin A (500U) + FES E2: Botulinum toxin A (500U) + Taping E3: Botulinum toxin A (500U) + Stretching Duration: 30min/session, 2sessions/d, 5d FES & 5d taping & 30min/session, 2sessions/d for 7d stretching	E1 vs E2 vs E3: Modified Ashworth Scale (-) Passive Range of Motion (-) Motor Action Potential (-) Max Dorsiflexion Angle in Stance Phase (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group
- indicates no statistically significant between groups differences at α=0.05
no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Mobilization Therapy or Placebo may produce greater improvements in motor recovery than Conventional Therapy or Placebo.	1	Li et al. 2024b
1a	Early and Intense Mobilization may not have a difference in efficacy when compared to Care for improving motor recovery.	2	Anjos et al. 2023; Bernhardt et al. 2008
1b	Dynamic Stretching (Tai Chi, Yoga, Pilates) may produce greater improvements in motor recovery than Conventional or No Therapy.	1	Haolin et al. 2024
1b	Daoyin with Conventional rehab may not have a difference in efficacy when compared to Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab for improving motor recovery.	1	Haolin et al. 2024
1b	Lower Limb Robot with Conventional rehab may not have a difference in efficacy when compared to Daoyin with Lower Limb Robot with Conventional rehab for improving motor recovery.	1	Haolin et al. 2024
1a	Body Weight Supported Dynamic Stretching may produce greater improvements in motor recovery than Conventional Therapy.	2	Yu et al. 2020a; Huang et al. 2019
1b	Proprioceptive Neuromuscular Facilitation with virtual reality may not have a difference in efficacy when compared to proprioceptive neuromuscular facilitation or virtual reality Alone for improving motor recovery.	1	Dos Santos Junior et al. 2019
1b	Chiropractic spinal adjustments + Physical Therapy may produce greater improvements in motor recovery than Sham chiropractic + physical therapy.	1	Holt et al. 2021
1b	Tai Chi Yunshou may produce greater improvements in motor recovery than Common Balance Rehabilitation Therapy.	1	Xie et al. 2018
1b	Baduanjin exercise training with Health education program may produce greater improvements in motor recovery than Health education program.	1	Ye et al. 2022
1b	Robot assisted ankle stretching device (Beijing LTK Science and Technology Co., Ltd., Beijing, China) may not have a difference in efficacy when compared to Manual stretching by the appointed physiotherapist for improving motor recovery.	1	Zhai et al. 2021
1b	Virtual Reality (Nintendo Wii) may not have a difference in efficacy when compared to Proprioceptive Neuromuscular Facilitation for improving motor recovery.	1	dos Santos Junior et al. 2019
1b	Virtual Reality (Nintendo Wii) may not have a difference in efficacy when compared to Virtual Reality with Proprioceptive Neuromuscular Facilitation for improving motor recovery.	1	dos Santos Junior et al. 2019
1b	Therapeutic ultrasound with passive stretching exercise may not have a difference in efficacy when compared to Passive stretching exercise for improving motor recovery.	1	Sahin et al. 2011

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Mobilization Therapy or Placebo may produce greater improvements in biomechanical gait measures than Conventional Therapy or Placebo.	4	Dengiz et al. 2024; Choi et al. 2023; Park et al. 2022; An et al. 2017
1b	Joint mobilization may result in lesser improvements in biomechanical gait measures when compared to Joint mobilization with active stretching.	1	Cho et al. 2020c
1b	Active Stretching may not have a difference in efficacy when compared to Joint mobilization with active stretching for improving biomechanical gait measures.	1	Cho et al. 2020c
1a	Mobilization With Movement may produce greater improvements in biomechanical gait measures than Muscle Stretching.	2	Park et al. 2020b; Park et al. 2019a
1b	There is conflicting evidence about the effect of Self-ankle mobilization with rehabilitation when compared to Self-ankle mobilization with 10-degree inclined board with rehabilitation for improving biomechanical gait measures.	1	Park et al. 2018b
1b	Body Weight Supported Dynamic Stretching may not have a difference in efficacy when compared to Conventional Therapy for improving biomechanical gait measures.	1	Yu et al. 2020a
2	Technology-Assisted Ankle Stretcher may not have a difference in efficacy when compared to Stretching Board for improving biomechanical gait measures.	1	Yoo et al. 2018a
1b	Isotonic muscle stretch with weight bearing may not have a difference in efficacy when compared to Healthy isotonic muscle stretch with weight bearing or Healthy isotonic stretch without weight bearing or Healthy isokinetic stretch for improving biomechanical gait measures.	1	Maynard et al. 2005
2	Proprioceptive neuromuscular facilitation-Based Gait Training may not have a difference in efficacy when compared to Conventional Gait Training for improving biomechanical gait measures.	1	Asghar et al. 2023
1b	Peripheral Nerve Mobilization with virtual reality-Based Gait Training may produce greater improvements in biomechanical gait measures than Conventional Exercises.	1	Vishnuram et al. 2024
2	Ankle Kinesio taping may result in lesser improvements in biomechanical gait measures when compared to Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (proprioceptive neuromuscular facilitation-KT).	1	Bae et al. 2022
2	Ankle Kinesio taping or Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (PNF-KT) may produce greater improvements in biomechanical gait measures than No Taping.	1	Bae et al. 2022
1b	Baduanjin exercise training with Health education program may not have a difference in efficacy when compared to Health education program for improving biomechanical gait measures.	1	Ye et al. 2022
2	Robotic ankle stretching exercises may not have a difference in efficacy when compared to Conventional stretching board 2d/wk, for 3.5wks (7 sessions total) for improving biomechanical gait measures.	1	Yoo et al. 2018a
2	Neurodevelopmental Bobath Concept Approach may produce greater improvements in biomechanical gait measures than proprioceptive neuromuscular facilitation method (proprioceptive neuromuscular facilitation).	1	Krukowska et al. 2016

2	There is conflicting evidence about the effect of Performance-based training with Anklebot stretching when compared to Manual stretching of ankle for improving biomechanical gait measures.	1	Forrester et al. 2014
1b	Stretching exercise with wearing toe spreader may not have a difference in efficacy when compared to No Orthotic (conventional care) for improving biomechanical gait measures.	1	Chiong et al. 2013
2	Robot assisted passive stretching and active movement training may produce greater improvements in biomechanical gait measures than At-home passive ankle stretching.	1	Waldman et al. 2013
2	Task-specific training with Ankle joint mobilizations may not have a difference in efficacy when compared to Task-specific training for improving biomechanical gait measures.	1	Kluding et al. 2008
1b	Botulinum toxin A (500U) with functional electrical stimulation may not have a difference in efficacy when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching for improving biomechanical gait measures.	1	Baricich et al. 2008

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Mobilization Therapy or Placebo may produce greater improvements in biomechanical balance measures than Conventional Therapy or Placebo.	5	Dengiz et al. 2024; Arabzadeh et al. 2023; Midan et al. 2022; Kim & Lee 2018a; An et al. 2017
1b	Sustained natural apophyseal glides with neurodevelopmental techniques may not have a difference in efficacy when compared to Maitland mobilization with neurodevelopmental techniques for improving biomechanical balance measures.	1	Kim et al. 2024c
1a	There is conflicting evidence about the effect of Dynamic Stretching (Tai Chi, Yoga, Pilates) when compared to Conventional or No Therapy for improving biomechanical balance measures.	3	Chan & Tsang 2017b; Lim et al. 2016; Au-Yeung et al. 2009
1b	Conventional exercises may not have a difference in efficacy when compared to No treatment for improving biomechanical balance measures.	1	Chan & Tsang 2017b
1b	Body Weight Supported Dynamic Stretching may not have a difference in efficacy when compared to Conventional Therapy for improving biomechanical balance measures.	1	Yu et al. 2020a
1b	There is conflicting evidence about the effect of Baduanjin Training when compared to Conventional Exercise for improving biomechanical balance measures.	1	Yuen et al. 2021
2	Technology-Assisted Ankle Stretcher may produce greater improvements in biomechanical balance measures than Stretching Board.	1	Yoo et al. 2018a
2	Robotic ankle stretching exercises may produce greater improvements in biomechanical balance measures than Conventional stretching board 2d/wk, for 3.5wks (7 sessions total).	1	Yoo et al. 2018a
2	There is conflicting evidence about the effect of Task-specific training with Ankle joint mobilizations when compared to Task-specific training for improving biomechanical balance measures.	1	Kluding et al. 2008

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Functional Stretching may not have a difference in efficacy when compared to Conventional Therapy for improving muscle strength.	1	Ghasemi et al. 2018

1a	Mobilization Therapy or Placebo may produce greater improvements in muscle strength than Conventional Therapy or Placebo.	2	Longo et al. 2023; An et al. 2017
1a	Dynamic Stretching (Tai Chi, Yoga, Pilates) may not have a difference in efficacy when compared to Conventional or No Therapy for improving muscle strength.	2	Lenoir Dit Caron et al. 2024; Song et al. 2021a
1b	Dynamic Stretching may not have a difference in efficacy when compared to SilverSneaker exercises or Usual care for improving muscle strength.	1	Taylor-Piliae et al. 2014
1b	Tai Chi may not have a difference in efficacy when compared to SilverSneakers exercises for improving muscle strength.	1	Taylor-Piliae et al. 2014
1b	Tai Chi or SilverSneakers exercises may not have a difference in efficacy when compared to Usual care for improving muscle strength.	1	Taylor-Piliae et al. 2014
1b	Early Proprioceptive Neuromuscular Facilitation may not have a difference in efficacy when compared to late Proprioceptive Neuromuscular Facilitation for improving muscle strength.	1	Morreale et al. 2016
1b	Proprioceptive Neuromuscular Facilitation may not have a difference in efficacy when compared to Conventional Therapy for improving muscle strength.	1	Rostami et al. 2024
2	Proprioceptive Neuromuscular Facilitation with Custom Exercises may not have a difference in efficacy when compared to Custom Exercises Alone for improving muscle strength.	1	Stern et al. 1970
2	Ankle Range of Motion Training may not have a difference in efficacy when compared to No Treatment for improving muscle strength.	1	Rydwik et al. 2006
1b	Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques may produce greater improvements in muscle strength than Talocrural joint only mobilization with neurodevelopmental techniques.	1	Buyukturan et al. 2022
1b	Baduanjin exercise training with Health education program may produce greater improvements in muscle strength than Health education program.	1	Ye et al. 2022
1b	Robot assisted ankle stretching device (Beijing LTK Science and Technology Co., Ltd., Beijing, China) may not have a difference in efficacy when compared to Manual stretching by the appointed physiotherapist for improving muscle strength.	1	Zhai et al. 2021
2	Performance-based training with Anklebot stretching may not have a difference in efficacy when compared to Manual stretching of ankle for improving muscle strength.	1	Forrester et al. 2014
2	Robot assisted passive stretching and active movement training may produce greater improvements in muscle strength than At-home passive ankle stretching.	1	Waldman et al. 2013
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may not have a difference in efficacy when compared to Botulinum toxin A (100U) with Taping and stretching and gait training for improving muscle strength.	1	Carda et al. 2011

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Functional Stretching may not have a difference in efficacy when compared to Conventional Therapy for improving spasticity.	2	Pradines et al. 2019; Ghasemi et al. 2018

1b	There is conflicting evidence about the effect of Mobilization Therapy or Placebo when compared to Conventional Therapy or Placebo for improving spasticity.	2	Li et al. 2024b; Longo et al. 2023
2	Ankle Range of Motion Training may not have a difference in efficacy when compared to No Treatment for improving spasticity.	1	Rydwik et al. 2006
1b	Stretching in a Supine Position may produce greater improvements in spasticity than Stretching in a Seated Position.	1	Fleuren et al. 2006
1b	Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises may produce greater improvements in spasticity than Sham Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises.	1	Nada et al. 2024
1b	Baduanjin exercise training with Health education program may not have a difference in efficacy when compared to Health education program for improving spasticity.	1	Ye et al. 2022
1b	Robot assisted ankle stretching device (Beijing LTK Science and Technology Co., Ltd., Beijing, China) may not have a difference in efficacy when compared to Manual stretching by the appointed physiotherapist for improving spasticity.	1	Zhai et al. 2021
2	Task-specific training may produce greater improvements in spasticity than Proprioceptive Neuromuscular Facilitation.	1	Anandan et al. 2020
1b	Whole Body Vibration (40 hz,4 mm) with Exercise (Stretching and active ROM exercise) may not have a difference in efficacy when compared to Sham Vibration with Exercise (Stretching and active ROM exercise) for improving spasticity.	1	Alp et al. 2018
2	Extracorporeal Shock Wave Therapy with stretching and Oral anti-spastic drugs may not have a difference in efficacy when compared to stretching with Oral anti-spastic drugs for improving spasticity.	1	Taheri et al. 2017
1b	Stretching exercise with wearing toe spreader may not have a difference in efficacy when compared to No Orthotic (conventional care) for improving spasticity.	1	Chiong et al. 2013
2	Robot assisted passive stretching and active movement training may produce greater improvements in spasticity than At-home passive ankle stretching.	1	Waldman et al. 2013

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Functional Stretching may not have a difference in efficacy when compared to Conventional Therapy for improving neurophysiological measures.	1	Ghasemi et al. 2018
1a	There is conflicting evidence about the effect of Mobilization Therapy or Placebo when compared to Conventional Therapy or Placebo for improving neurophysiological measures.	3	Arabzadeh et al. 2023; Longo et al. 2023; Navid et al. 2022
1b	Stretching in a Supine Position may produce greater improvements in neurophysiological measures than Stretching in a Seated Position.	1	Fleuren et al. 2006
1b	Therapeutic ultrasound with passive stretching exercise may not have a difference in efficacy when compared to Passive stretching exercise for improving neurophysiological measures.	1	Sahin et al. 2011

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Early and Intense Mobilization may not have a difference in efficacy when compared to Care for improving aerobic measures.	1	Bernhardt et al. 2008

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Proprioceptive Neuromuscular Facilitation with virtual reality may not have a difference in efficacy when compared to proprioceptive neuromuscular facilitation or virtual reality Alone for improving sensory and proprioceptive function.	1	Dos Santos Junior et al. 2019
1b	Virtual Reality (Nintendo Wii) may not have a difference in efficacy when compared to Proprioceptive Neuromuscular Facilitation for improving sensory and proprioceptive function.	1	dos Santos Junior et al. 2019

PAIN			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Mobilization Therapy or Placebo may not have a difference in efficacy when compared to Conventional Therapy or Placebo for improving pain.	1	Lee et al. 2023b

1b	Joint mobilization with acupuncture may not have a difference in efficacy when compared to Joint mobilization for improving pain.	1	Lee et al. 2023b
2	Extracorporeal Shock Wave Therapy with stretching and Oral anti-spastic drugs may not have a difference in efficacy when compared to stretching with Oral anti-spastic drugs for improving pain.	1	Taheri et al. 2017

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Mobilization Therapy or Placebo may produce greater improvements in activities of daily living than Conventional Therapy or Placebo.	2	Lee et al. 2023b; Longo et al. 2023
1b	Joint mobilization with acupuncture may not have a difference in efficacy when compared to Joint mobilization for improving activities of daily living.	1	Lee et al. 2023b
1b	Early and Intense Mobilization may not have a difference in efficacy when compared to Care for improving activities of daily living.	1	Anjos et al. 2023
1b	Self-ankle mobilization with rehabilitation may not have a difference in efficacy when compared to Self-ankle mobilization with 10-degree inclined board with rehabilitation for improving activities of daily living.	1	Park et al. 2018b
1a	Dynamic Stretching (Tai Chi, Yoga, Pilates) may produce greater improvements in activities of daily living than Conventional or No Therapy.	5	Garcia-Bravo et al. 2024; Haolin et al. 2024; Lenoir Dit Caron et al. 2024; Zhao et al. 2022a; Song et al. 2021a
1b	There is conflicting evidence about the effect of Daoyin with Conventional rehab when compared to Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab for improving activities of daily living.	1	Haolin et al. 2024
1b	Lower Limb Robot with Conventional rehab may not have a difference in efficacy when compared to Daoyin with Lower Limb Robot with Conventional rehab for improving activities of daily living.	1	Haolin et al. 2024
1b	Early Proprioceptive Neuromuscular Facilitation may not have a difference in efficacy when compared to late Proprioceptive Neuromuscular Facilitation for improving activities of daily living.	1	Morreale et al. 2016
1b	Baduanjin Training may not have a difference in efficacy when compared to Conventional Exercise for improving activities of daily living.	1	Yuen et al. 2021
2	Proprioceptive Neuromuscular Facilitation with Custom Exercises may not have a difference in efficacy when compared to Custom Exercises Alone for improving activities of daily living.	1	Stern et al. 1970
2	Ankle Range of Motion Training may not have a difference in efficacy when compared to No Treatment for improving activities of daily living.	1	Rydwik et al. 2006
1b	Chiropractic spinal adjustments + Physical Therapy may not have a difference in efficacy when compared to Sham chiropractic + physical therapy for improving activities of daily living.	1	Holt et al. 2021
1b	Tai Chi Yunshou may not have a difference in efficacy when compared to Common Balance Rehabilitation Therapy for improving activities of daily living.	1	Xie et al. 2018
1b	Robot assisted ankle stretching device (Beijing LTK Science and Technology Co., Ltd., Beijing, China) may not have a difference in	1	Zhai et al. 2021

	efficacy when compared to Manual stretching by the appointed physiotherapist for improving activities of daily living.		
1b	Whole Body Vibration (40 hz,4 mm) with Exercise (Stretching and active ROM exercise) may not have a difference in efficacy when compared to Sham Vibration with Exercise (Stretching and active ROM exercise) for improving activities of daily living.	1	Alp et al. 2018
2	Aquatic therapy (based on proprioceptive neuromuscular facilitation) may produce greater improvements in activities of daily living than Proprioceptive neuromuscular facilitation on the ground.	1	Kim et al. 2015f
2	Performance-based training with Anklebot stretching may not have a difference in efficacy when compared to Manual stretching of ankle for improving activities of daily living.	1	Forrester et al. 2014

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Functional Stretching may produce greater improvements in gait speed than Conventional Therapy.	1	Pradines et al. 2019
1a	There is conflicting evidence about the effect of Mobilization Therapy or Placebo when compared to Conventional Therapy or Placebo for improving gait speed.	5	Traxler et al. 2024; Dengiz et al. 2024; Lee et al. 2023b; Choi et al. 2023; Park et al. 2022
1b	Manual therapy with task oriented training and home exercise program may not have a difference in efficacy when compared to task oriented training with home exercise program for improving gait speed.	1	Traxler et al. 2024
1b	Sustained natural apophyseal glides with neurodevelopmental techniques may not have a difference in efficacy when compared to Maitland mobilization with neurodevelopmental techniques for improving gait speed.	1	Kim et al. 2024c
1b	Joint mobilization with acupuncture may not have a difference in efficacy when compared to Joint mobilization for improving gait speed.	1	Lee et al. 2023b
1b	Joint mobilization may result in lesser improvements in gait speed when compared to Joint mobilization with active stretching.	1	Cho et al. 2020c
1b	Active Stretching may not have a difference in efficacy when compared to Joint mobilization with active stretching for improving gait speed.	1	Cho et al. 2020c
1a	There is conflicting evidence about the effect of Mobilization With Movement when compared to Muscle Stretching for improving gait speed.	2	Park et al. 2020b; Park et al. 2019a
1b	Self-ankle mobilization with rehabilitation may result in lesser improvements in gait speed when compared to Self-ankle mobilization with 10-degree inclined board with rehabilitation.	1	Park et al. 2018b
1b	There is conflicting evidence about the effect of Dynamic Stretching (Tai Chi, Yoga, Pilates) when compared to Conventional or No Therapy for improving gait speed.	2	Chan & Tsang 2017b; Kim et al. 2015d
1b	Body Weight Supported Dynamic Stretching may not have a difference in efficacy when compared to Conventional Therapy for improving gait speed.	1	Yu et al. 2020a
2	Technology-Assisted Ankle Stretcher may not have a difference in efficacy when compared to Stretching Board for improving gait speed.	1	Yoo et al. 2018a
1b	Isotonic muscle stretch with weight bearing may not have a difference in efficacy when compared to Healthy isotonic muscle	1	Maynard et al. 2005

	stretch with weight bearing or Healthy isotonic stretch without weight bearing or Healthy isokinetic stretch for improving gait speed.		
2	There is conflicting evidence about the effect of Ankle Range of Motion Training when compared to No Treatment for improving gait speed.	1	Rydwik et al. 2006
2	Proprioceptive neuromuscular facilitation-Based Gait Training may not have a difference in efficacy when compared to Conventional Gait Training for improving gait speed.	1	Asghar et al. 2023
1b	Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques may produce greater improvements in gait speed than Talocrural joint only mobilization with neurodevelopmental techniques.	1	Buyukturan et al. 2022
1b	Peripheral Nerve Mobilization with virtual reality-Based Gait Training may produce greater improvements in gait speed than Conventional Exercises.	1	Vishnuram et al. 2024
1b	Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises may produce greater improvements in gait speed than Sham Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises.	1	Nada et al. 2024
2	Ankle Kinesio taping may result in lesser improvements in gait speed when compared to Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (proprioceptive neuromuscular facilitation-KT).	1	Bae et al. 2022
2	Ankle Kinesio taping or Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (PNF-KT) may produce greater improvements in gait speed than No Taping.	1	Bae et al. 2022
1b	Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may not have a difference in efficacy when compared to Convetional physiotherapy for improving gait speed.	1	Tedla et al. 2022
1b	Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may not have a difference in efficacy when compared to Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy for improving gait speed.	1	Tedla et al. 2022
1b	Baduanjin exercise training with Health education program may produce greater improvements in gait speed than Health education program.	1	Ye et al. 2022
2	Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may produce greater improvements in gait speed than Sham taping with treadmill training.	1	Kim & Kang 2018c
2	Robotic ankle stretching exercises may not have a difference in efficacy when compared to Conventional stretching board 2d/wk, for 3.5wks (7 sessions total) for improving gait speed.	1	Yoo et al. 2018a
1b	Whole Body Vibration (40 hz,4 mm) with Exercise (Stretching and active ROM exercise) may produce greater improvements in gait speed than Sham Vibration with Exercise (Stretching and active ROM exercise).	1	Alp et al. 2018
2	Extracorporeal Shock Wave Therapy with stretching and Oral anti-spastic drugs may not have a difference in efficacy when compared to stretching with Oral anti-spastic drugs for improving gait speed.	1	Taheri et al. 2017

2	Aquatic therapy (based on proprioceptive neuromuscular facilitation) may produce greater improvements in gait speed than Conventional therapy.	1	Kim et al. 2015b
2	Performance-based training with Anklebot stretching may produce greater improvements in gait speed than Manual stretching of ankle.	1	Forrester et al. 2014
1b	Stretching exercise with wearing toe spreader may not have a difference in efficacy when compared to No Orthotic (conventional care) for improving gait speed.	1	Chiong et al. 2013
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may not have a difference in efficacy when compared to Botulinum toxin A (100U) with Taping and stretching and gait training for improving gait speed.	1	Carda et al. 2011

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Sustained natural apophyseal glides with neurodevelopmental techniques may not have a difference in efficacy when compared to Maitland mobilization with neurodevelopmental techniques for improving gait endurance.	1	Kim et al. 2024c
1a	Dynamic Stretching (Tai Chi, Yoga, Pilates) may not have a difference in efficacy when compared to Conventional or No Therapy for improving gait endurance.	2	Lenoir Dit Caron et al. 2024; Immink et al. 2014
1b	Early Proprioceptive Neuromuscular Facilitation may not have a difference in efficacy when compared to late Proprioceptive Neuromuscular Facilitation for improving gait endurance.	1	Morreale et al. 2016
2	Ankle Range of Motion Training may not have a difference in efficacy when compared to No Treatment for improving gait endurance.	1	Rydwik et al. 2006
2	Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may produce greater improvements in gait endurance than Sham taping with treadmill training.	1	Kim & Kang 2018c
2	Robot assisted passive stretching and active movement training may not have a difference in efficacy when compared to At-home passive ankle stretching for improving gait endurance.	1	Waldman et al. 2013
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may not have a difference in efficacy when compared to Botulinum toxin A (100U) with Taping and stretching and gait training for improving gait endurance.	1	Carda et al. 2011

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Mobilization Therapy or Placebo may produce greater improvements in functional mobility than Conventional Therapy or Placebo.	6	Traxler et al. 2024; Dengiz et al. 2024; Arabzadeh et al. 2023; Choi et al. 2023; Longo et al. 2023; Kim & Lee 2018a
1b	Manual therapy with task oriented training and home exercise program may not have a difference in efficacy when compared to task oriented training with home exercise program for improving functional mobility.	1	Traxler et al. 2024
1b	Sustained natural apophyseal glides with neurodevelopmental techniques may not have a difference in efficacy when compared to Maitland mobilization with neurodevelopmental techniques for improving functional mobility.	1	Kim et al. 2024c

1b	Early and Intense Mobilization may not have a difference in efficacy when compared to Care for improving functional mobility.	1	Anjos et al. 2023
1a	Dynamic Stretching (Tai Chi, Yoga, Pilates) may not have a difference in efficacy when compared to Conventional or No Therapy for improving functional mobility.	7	Garcia-Bravo et al. 2024; Lenoir Dit Caron et al. 2024; Song et al. 2021a; Chan & Tsang 2018; Kim et al. 2015d; Immink et al. 2014; Au-Yeung et al. 2009
1b	Dynamic Stretching may not have a difference in efficacy when compared to SilverSneaker exercises or Usual care for improving functional mobility.	1	Taylor-Piliae et al. 2014
1b	Tai Chi may not have a difference in efficacy when compared to SilverSneakers exercises for improving functional mobility.	1	Taylor-Piliae et al. 2014
1b	Baduanjin Training may produce greater improvements in functional mobility than Conventional Exercise.	1	Yuen et al. 2021
2	Proprioceptive Neuromuscular Facilitation with Electrical Stimulation may not have a difference in efficacy when compared to proprioceptive neuromuscular facilitation Alone for improving functional mobility.	1	Shim et al. 2020
2	Ankle Range of Motion Training may not have a difference in efficacy when compared to No Treatment for improving functional mobility.	1	Rydwik et al. 2006
2	Proprioceptive neuromuscular facilitation-Based Gait Training may not have a difference in efficacy when compared to Conventional Gait Training for improving functional mobility.	1	Asghar et al. 2023
1b	Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques may produce greater improvements in functional mobility than Talocrural joint only mobilization with neurodevelopmental techniques.	1	Buyukturan et al. 2022
1b	Chiropractic spinal adjustments + Physical Therapy may not have a difference in efficacy when compared to Sham chiropractic + physical therapy for improving functional mobility.	1	Holt et al. 2021

1b	Tai Chi or SilverSneakers exercises may not have a difference in efficacy when compared to Usual care for improving fatigue and sleep.	1	Taylor-Piliae et al. 2014

COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Dynamic Stretching (Tai Chi, Yoga, Pilates) when compared to Conventional or No Therapy for improving cognition.	3	Song et al. 2021a; Chan & Tsang 2018; Chan & Tsang 2017b
1b	Conventional exercises may not have a difference in efficacy when compared to No treatment for improving cognition.	1	Chan & Tsang 2017b
1b	Early Proprioceptive Neuromuscular Facilitation may not have a difference in efficacy when compared to late Proprioceptive Neuromuscular Facilitation for improving cognition.	1	Morreale et al. 2016

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Mobilization Therapy or Placebo may not have a difference in efficacy when compared to Conventional Therapy or Placebo for improving upper extremity function.	2	Arabzadeh et al. 2023; Lee et al. 2023b
1b	Joint mobilization with acupuncture may not have a difference in efficacy when compared to Joint mobilization for improving upper extremity function.	1	Lee et al. 2023b
1a	Dynamic Stretching (Tai Chi, Yoga, Pilates) may not have a difference in efficacy when compared to Conventional or No Therapy for improving upper extremity function.	2	Garcia-Bravo et al. 2024; Zhao et al. 2022a
1b	There is conflicting evidence about the effect of Chiropractic spinal adjustments + Physical Therapy when compared to Sham chiropractic + physical therapy for improving upper extremity function.	1	Holt et al. 2021
1b	Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may produce greater improvements in upper extremity function than Convetional physiotherapy.	1	Tedla et al. 2022
1b	Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may produce greater improvements in upper extremity function than Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy.	1	Tedla et al. 2022
1b	There is conflicting evidence about the effect of Baduanjin exercise training with Health education program when compared to Health education program for improving upper extremity function.	1	Ye et al. 2022
2	Task-specific training may produce greater improvements in upper extremity function than Proprioceptive Neuromuscular Facilitation.	1	Anandan et al. 2020

Key Points

- Functional Stretching may be beneficial for improving gait speed, but not muscle strength, spasticity, range of motion, and neurophysiological measures, after stroke when compared to Conventional Therapy.
- Mobilization Therapy or Placebo may be beneficial for improving motor recovery, biomechanical gait measures, biomechanical balance measures, muscle strength, range of motion, activities of daily living,

functional mobility, balance, and quality of life, but not pain, after stroke when compared to Conventional Therapy or Placebo; the literature is mixed regarding spasticity, neurophysiological measures, and gait speed.

- Manual therapy with task oriented training and home exercise program may be beneficial for improving range of motion, but not gait speed, functional mobility, balance, and quality of life, after stroke when compared to task oriented training with home exercise program.
- Sustained natural apophyseal glides with neurodevelopmental techniques may not be beneficial for improving biomechanical balance measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Maitland mobilization with neurodevelopmental techniques.
- Joint mobilization with acupuncture may not be beneficial for improving range of motion, pain, activities of daily living, and gait speed after stroke when compared to Joint mobilization.
- Early and Intense Mobilization may not be beneficial for improving motor recovery, aerobic measures, activities of daily living, functional mobility, and balance after stroke when compared to Care.
- Joint mobilization may result in lesser improvements in biomechanical gait measures and gait speed when compared to Joint mobilization with active stretching; the literature is mixed regarding range of motion.
- Active Stretching may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Joint mobilization with active stretching; the literature is mixed regarding range of motion.
- Mobilization With Movement may be beneficial for improving biomechanical gait measures, balance, and falls and fear of falling after stroke when compared to Muscle Stretching; the literature is mixed regarding range of motion and gait speed.
- Self-ankle mobilization with rehabilitation may not be beneficial for improving activities of daily living after stroke when compared to Self-ankle mobilization with 10-degree inclined board with rehabilitation; Self-ankle mobilization with rehabilitation may result in lesser improvements in range of motion and gait speed when compared to Self-ankle mobilization with 10-degree inclined board with rehabilitation; the literature is mixed regarding biomechanical gait measures and balance.
- Dynamic Stretching (Tai Chi, Yoga, Pilates) may be beneficial for improving motor recovery, activities of daily living, and balance, but not muscle strength, range of motion, gait endurance, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Conventional or No Therapy; the literature is mixed regarding biomechanical balance measures and gait speed.
- Daoyin with Conventional rehab may not be beneficial for improving motor recovery and balance after stroke when compared to Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab; the literature is mixed regarding activities of daily living.
- Dynamic Stretching may be beneficial for improving falls and fear of falling, but not muscle strength, functional mobility, balance, and quality of life, after stroke when compared to SilverSneaker exercises or Usual care.
- Tai Chi may not be beneficial for improving muscle strength, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to SilverSneakers exercises.
- Body Weight Supported Dynamic Stretching may be beneficial for improving motor recovery and falls and fear of falling, but not biomechanical gait measures, biomechanical balance measures, gait speed, and balance, after stroke when compared to Conventional Therapy.
- Early Proprioceptive Neuromuscular Facilitation may not be beneficial for improving muscle strength, activities of daily living, and gait endurance after stroke when compared to late Proprioceptive Neuromuscular Facilitation.
- Baduanjin Training may be beneficial for improving functional mobility and balance, but not activities of daily living, falls and fear of falling, and quality of life, after stroke when compared to Conventional Exercise; the literature is mixed regarding biomechanical balance measures.
- Proprioceptive Neuromuscular Facilitation may be beneficial for improving balance, but not muscle strength, after stroke when compared to Conventional Therapy; the literature is mixed regarding range of motion.
- Proprioceptive Neuromuscular Facilitation with Custom Exercises may not be beneficial for improving muscle strength and activities of daily living after stroke when compared to Custom Exercises Alone.

- Proprioceptive Neuromuscular Facilitation with virtual reality may not be beneficial for improving motor recovery, sensory and proprioceptive function, and balance after stroke when compared to proprioceptive neuromuscular facilitation or virtual reality Alone.
- Proprioceptive Neuromuscular Facilitation with Electrical Stimulation may not be beneficial for improving functional mobility and balance after stroke when compared to proprioceptive neuromuscular facilitation Alone.
- Technology-Assisted Ankle Stretcher may be beneficial for improving biomechanical balance measures and range of motion, but not biomechanical gait measures and gait speed, after stroke when compared to Stretching Board.
- Isotonic muscle stretch with weight bearing may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Healthy isotonic muscle stretch with weight bearing or Healthy isotonic stretch without weight bearing or Healthy isokinetic stretch.
- Ankle Range of Motion Training may not be beneficial for improving muscle strength, spasticity, activities of daily living, gait endurance, functional mobility, balance, and quality of life after stroke when compared to No Treatment; the literature is mixed regarding gait speed.
- Stretching in a Supine Position may be beneficial for improving spasticity and neurophysiological measures after stroke when compared to Stretching in a Seated Position.
- Proprioceptive neuromuscular facilitation-Based Gait Training may be beneficial for improving balance, but not biomechanical gait measures, gait speed, and functional mobility, after stroke when compared to Conventional Gait Training.
- Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques may be beneficial for improving muscle strength, gait speed, functional mobility, and balance after stroke when compared to Talocrural joint only mobilization with neurodevelopmental techniques.
- Peripheral Nerve Mobilization with virtual reality-Based Gait Training may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Conventional Exercises.
- Chiropractic spinal adjustments + Physical Therapy may be beneficial for improving motor recovery, but not activities of daily living, functional mobility, and quality of life, after stroke when compared to Sham chiropractic + physical therapy.
- Tai Chi Yunshou may be beneficial for improving motor recovery, but not activities of daily living, functional mobility, and balance, after stroke when compared to Common Balance Rehabilitation Therapy; the literature is mixed regarding falls and fear of falling.
- Tai Chi Chuan exercises may not be beneficial for improving functional mobility, balance, and quality of life after stroke when compared to Conventional care physiotherapy.
- Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises may be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to Sham Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises.
- Ankle Kinesio taping may result in lesser improvements in biomechanical gait measures, range of motion, and gait speed when compared to Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (proprioceptive neuromuscular facilitation-KT).
- Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may be beneficial for improving balance and quality of life, but not gait speed, after stroke when compared to Convetional physiotherapy.
- Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may be beneficial for improving balance and quality of life, but not gait speed, after stroke when compared to Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy.
- Baduanjin exercise training with Health education program may be beneficial for improving motor recovery, muscle strength, gait speed, and balance, but not biomechanical gait measures and spasticity, after stroke when compared to Health education program.
- Robot assisted ankle stretching device (Beijing LTK Science and Technology Co., Ltd., Beijing, China) may not be beneficial for improving motor recovery, muscle strength, spasticity, range of motion, activities of daily living, and balance after stroke when compared to Manual stretching by the appointed physiotherapist.

- Task-specific training may be beneficial for improving spasticity, functional mobility, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Virtual Reality (Nintendo Wii) may not be beneficial for improving motor recovery, sensory and proprioceptive function, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Virtual Reality (Nintendo Wii) may not be beneficial for improving motor recovery after stroke when compared to Virtual Reality with Proprioceptive Neuromuscular Facilitation.
- Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may be beneficial for improving gait speed, gait endurance, and functional mobility after stroke when compared to Sham taping with treadmill training.
- Robotic ankle stretching exercises may be beneficial for improving biomechanical balance measures and range of motion, but not biomechanical gait measures and gait speed, after stroke when compared to Conventional stretching board 2d/wk, for 3.5wks (7 sessions total).
- Whole Body Vibration (40 hz,4 mm) with Exercise (Stretching and active ROM exercise) may be beneficial for improving gait speed, but not spasticity and activities of daily living, after stroke when compared to Sham Vibration with Exercise (Stretching and active ROM exercise).
- Extracorporeal Shock Wave Therapy with stretching and Oral anti-spastic drugs may not be beneficial for improving spasticity, range of motion, pain, and gait speed after stroke when compared to stretching with Oral anti-spastic drugs.
- Neurodevelopmental Bobath Concept Approach may be beneficial for improving biomechanical gait measures after stroke when compared to proprioceptive neuromuscular facilitation method (proprioceptive neuromuscular facilitation).
- Aquatic therapy (based on proprioceptive neuromuscular facilitation) may be beneficial for improving activities of daily living, functional mobility, and balance after stroke when compared to Proprioceptive neuromuscular facilitation on the ground.
- Aquatic therapy (based on proprioceptive neuromuscular facilitation) may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to Conventional therapy.
- Performance-based training with Anklebot stretching may be beneficial for improving gait speed, but not muscle strength, range of motion, activities of daily living, and balance, after stroke when compared to Manual stretching of ankle; the literature is mixed regarding biomechanical gait measures.
- Stretching exercise with wearing toe spreader may not be beneficial for improving biomechanical gait measures, spasticity, gait speed, and balance after stroke when compared to No Orthotic (conventional care).
- Robot assisted passive stretching and active movement training may be beneficial for improving biomechanical gait measures, muscle strength, spasticity, functional mobility, and balance, but not gait endurance, after stroke when compared to At-home passive ankle stretching; the literature is mixed regarding range of motion.
- Therapeutic ultrasound with passive stretching exercise may not be beneficial for improving motor recovery, spasticity, range of motion, and neurophysiological measures after stroke when compared to Passive stretching exercise.
- Botulinum toxin A (100U) with Serial casting and stretching and gait training may be beneficial for improving spasticity and range of motion, but not muscle strength, gait speed, gait endurance, and functional mobility, after stroke when compared to Botulinum toxin A (100U) with Taping and stretching and gait training.
- Task-specific training with Ankle joint mobilizations may be beneficial for improving range of motion, but not biomechanical gait measures, after stroke when compared to Task-specific training; the literature is mixed regarding biomechanical balance measures and functional mobility.
- Botulinum toxin A (500U) with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, spasticity, and range of motion after stroke when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching.
- Lower Limb Robot with Conventional rehab may not be beneficial for improving motor recovery, activities of daily living, and balance after stroke when compared to Daoyin with Lower Limb Robot with Conventional rehab.

- Conventional exercises may not be beneficial for improving biomechanical balance measures after stroke when compared to No treatment.
- Tai Chi may be beneficial for improving falls and fear of falling, but not muscle strength, balance, and quality of life, after stroke when compared to Usual care.
- SilverSneakers exercises may not be beneficial for improving falls and fear of falling, muscle strength, balance, and quality of life after stroke when compared to Usual care.
- Ankle Kinesio taping may be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to No Taping.
- Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (PNF-KT) may be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to No Taping.

Summary of Key Points: Stretching or Mobilization Exercises

Intervention	Control(s)	Function domain(s)	Effect
Functional Stretching	Conventional Therapy	Gait speed	+
Functional Stretching	Conventional Therapy	Muscle strength, spasticity, range of motion, neurophysiological measures	–
Mobilization Therapy or Placebo	Conventional Therapy or Placebo	Motor recovery, biomechanical gait measures, biomechanical balance measures, muscle strength, range of motion, activities of daily living, functional mobility, balance, quality of life	+
Mobilization Therapy or Placebo	Conventional Therapy or Placebo	Pain	–
Mobilization Therapy or Placebo	Conventional Therapy or Placebo	Spasticity, neurophysiological measures, gait speed	=
Manual therapy with task oriented training and home exercise program	task oriented training with home exercise program	Range of motion	+
Manual therapy with task oriented training and home exercise program	task oriented training with home exercise program	Gait speed, functional mobility, balance, quality of life	–
Sustained natural apophyseal glides with neurodevelopmental techniques	Maitland mobilization with neurodevelopmental techniques	Biomechanical balance measures, gait speed, gait endurance, functional mobility, balance	–
Joint mobilization with acupuncture	Joint mobilization	Range of motion, pain, activities of daily living, gait speed	–
Early and Intense Mobilization	Care	Motor recovery, aerobic measures, activities of daily living, functional mobility, balance	–
Joint mobilization	Joint mobilization with active stretching	Biomechanical gait measures, gait speed	–
Joint mobilization	Joint mobilization with active stretching	Range of motion	=
Active Stretching	Joint mobilization with active stretching	Biomechanical gait measures, gait speed	–
Active Stretching	Joint mobilization with active stretching	Range of motion	=
Mobilization With Movement	Muscle Stretching	Biomechanical gait measures, balance, falls and fear of falling	+

Mobilization With Movement	Muscle Stretching	Range of motion, gait speed	=
Self-ankle mobilization with rehabilitation	Self-ankle mobilization with 10-degree inclined board with rehabilitation	Activities of daily living	–
Self-ankle mobilization with rehabilitation	Self-ankle mobilization with 10-degree inclined board with rehabilitation	Range of motion, gait speed	–
Self-ankle mobilization with rehabilitation	Self-ankle mobilization with 10-degree inclined board with rehabilitation	Biomechanical gait measures, balance	=
Dynamic Stretching (Tai Chi, Yoga, Pilates)	Conventional or No Therapy	Motor recovery, activities of daily living, balance	+
Dynamic Stretching (Tai Chi, Yoga, Pilates)	Conventional or No Therapy	Muscle strength, range of motion, gait endurance, functional mobility, falls and fear of falling, quality of life	–
Dynamic Stretching (Tai Chi, Yoga, Pilates)	Conventional or No Therapy	Biomechanical balance measures, gait speed	=
Daoyin with Conventional rehab	Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab	Motor recovery, balance	–
Daoyin with Conventional rehab	Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab	Activities of daily living	=
Dynamic Stretching	SilverSneaker exercises vs Usual care	Falls and fear of falling	+
Dynamic Stretching	SilverSneaker exercises vs Usual care	Muscle strength, functional mobility, balance, quality of life	–
Tai Chi	SilverSneakers exercises	Muscle strength, functional mobility, balance, falls and fear of falling, quality of life	–
Body Weight Supported Dynamic Stretching	Conventional Therapy	Motor recovery, falls and fear of falling	+
Body Weight Supported Dynamic Stretching	Conventional Therapy	Biomechanical gait measures, biomechanical balance measures, gait speed, balance	–
Early Proprioceptive Neuromuscular Facilitation	late Proprioceptive Neuromuscular Facilitation	Muscle strength, activities of daily living, gait endurance	–
Baduanjin Training	Conventional Exercise	Functional mobility, balance	+
Baduanjin Training	Conventional Exercise	Activities of daily living, falls and fear of falling, quality of life	–
Baduanjin Training	Conventional Exercise	Biomechanical balance measures	=
Proprioceptive Neuromuscular Facilitation	Conventional Therapy	Balance	+
Proprioceptive Neuromuscular Facilitation	Conventional Therapy	Muscle strength	–
Proprioceptive Neuromuscular Facilitation	Conventional Therapy	Range of motion	=

Proprioceptive Neuromuscular Facilitation with Custom Exercises	Custom Exercises Alone	Muscle strength, activities of daily living	–
Proprioceptive Neuromuscular Facilitation with virtual reality	proprioceptive neuromuscular facilitation or virtual reality Alone	Motor recovery, sensory and proprioceptive function, balance	–
Proprioceptive Neuromuscular Facilitation with virtual reality	proprioceptive neuromuscular facilitation or virtual reality Alone	Motor recovery	–
Proprioceptive Neuromuscular Facilitation with Electrical Stimulation	proprioceptive neuromuscular facilitation Alone	Functional mobility, balance	–
Technology-Assisted Ankle Stretcher	Stretching Board	Biomechanical balance measures, range of motion	+
Technology-Assisted Ankle Stretcher	Stretching Board	Biomechanical gait measures, gait speed	–
Isotonic muscle stretch with weight bearing	Healthy isotonic muscle stretch with weight bearing or Healthy isotonic stretch without weight bearing or Healthy isokinetic stretch	Biomechanical gait measures, gait speed	–
Ankle Range of Motion Training	No Treatment	Muscle strength, spasticity, activities of daily living, gait endurance, functional mobility, balance, quality of life	–
Ankle Range of Motion Training	No Treatment	Gait speed	=
Stretching in a Supine Position	Stretching in a Seated Position	Spasticity, neurophysiological measures	+
Proprioceptive neuromuscular facilitation-Based Gait Training	Conventional Gait Training	Balance	+
Proprioceptive neuromuscular facilitation-Based Gait Training	Conventional Gait Training	Biomechanical gait measures, gait speed, functional mobility	–
Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques	Talocrural joint only mobilization with neurodevelopmental techniques	Muscle strength, gait speed, functional mobility, balance	+
Peripheral Nerve Mobilization with virtual reality-Based Gait Training	Conventional Exercises	Biomechanical gait measures, gait speed	+
Chiropractic spinal adjustments + Physical Therapy	Sham chiropractic + physical therapy	Motor recovery	+
Chiropractic spinal adjustments + Physical Therapy	Sham chiropractic + physical therapy	Activities of daily living, functional mobility, quality of life	–
Tai Chi Yunshou	Common Balance Rehabilitation Therapy	Motor recovery	+
Tai Chi Yunshou	Common Balance Rehabilitation Therapy	Activities of daily living, functional mobility, balance	–
Tai Chi Yunshou	Common Balance Rehabilitation Therapy	Falls and fear of falling	=
Tai Chi Chuan exercises	Conventional care physiotherapy	Functional mobility, balance, quality of life	–
Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises	Sham Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises	Spasticity, range of motion, gait speed	+
Ankle Kinesio taping	Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping	Biomechanical gait measures, range of motion, gait speed	–

	(proprioceptive neuromuscular facilitation-KT)		
Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy	Convetional physiotherapy	Balance, quality of life	+
Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy	Convetional physiotherapy	Gait speed	−
Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy	Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy	Balance, quality of life	+
Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy	Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy	Gait speed	−
Baduanjin exercise training with Health education program	Health education program	Motor recovery, muscle strength, gait speed, balance	+
Baduanjin exercise training with Health education program	Health education program	Biomechanical gait measures, spasticity	−
Robot assisted ankle stretching device (Beijing LTK Science and Technology Co., Ltd., Beijing, China)	Manual stretching by the appointed physiotherapist	Motor recovery, muscle strength, spasticity, range of motion, activities of daily living, balance	−
Task-specific training	Proprioceptive Neuromuscular Facilitation	Spasticity, functional mobility, balance	+
Virtual Reality (Nintendo Wii)	Proprioceptive Neuromuscular Facilitation	Motor recovery, sensory and proprioceptive function, balance	−
Virtual Reality (Nintendo Wii)	Virtual Reality with Proprioceptive Neuromuscular Facilitation	Motor recovery	−
Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT)	Sham taping with treadmill training	Gait speed, gait endurance, functional mobility	+
Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT)	Sham taping with treadmill training	Gait endurance, functional mobility	+
Robotic ankle stretching exercises	Conventional stretching board 2d/wk, for 3.5wks (7 sessions total)	Biomechanical balance measures, range of motion	+
Robotic ankle stretching exercises	Conventional stretching board 2d/wk, for 3.5wks (7 sessions total)	Biomechanical gait measures, gait speed	−
Whole Body Vibration (40 hz,4 mm) with Exercise (Stretching and active ROM exercise)	Sham Vibration with Exercise (Stretching and active ROM exercise)	Gait speed	+
Whole Body Vibration (40 hz,4 mm) with Exercise (Stretching and active ROM exercise)	Sham Vibration with Exercise (Stretching and active ROM exercise)	Spasticity, activities of daily living	−

Extracorporeal Shock Wave Therapy with stretching and Oral anti-spastic drugs	stretching with Oral anti-spastic drugs	Spasticity, range of motion, pain, gait speed	–
Neurodevelopmental Bobath Concept Approach	proprioceptive neuromuscular facilitation method (proprioceptive neuromuscular facilitation)	Biomechanical gait measures	+
Aquatic therapy (based on proprioceptive neuromuscular facilitation)	Proprioceptive neuromuscular facilitation on the ground	Activities of daily living, functional mobility, balance	+
Aquatic therapy (based on proprioceptive neuromuscular facilitation)	Conventional therapy	Gait speed, functional mobility, balance	+
Performance-based training with Anklebot stretching	Manual stretching of ankle	Gait speed	+
Performance-based training with Anklebot stretching	Manual stretching of ankle	Muscle strength, range of motion, activities of daily living, balance	–
Performance-based training with Anklebot stretching	Manual stretching of ankle	Biomechanical gait measures	=
Stretching exercise with wearing toe spreader	No Orthotic (conventional care)	Biomechanical gait measures, spasticity, gait speed, balance	–
Robot assisted passive stretching and active movement training	At-home passive ankle stretching	Biomechanical gait measures, muscle strength, spasticity, functional mobility, balance	+
Robot assisted passive stretching and active movement training	At-home passive ankle stretching	Gait endurance	–
Robot assisted passive stretching and active movement training	At-home passive ankle stretching	Range of motion	=
Therapeutic ultrasound with passive stretching exercise	Passive stretching exercise	Motor recovery, spasticity, range of motion, neurophysiological measures	–
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with Taping and stretching and gait training	Spasticity, range of motion	+
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with Taping and stretching and gait training	Muscle strength, gait speed, gait endurance, functional mobility	–
Task-specific training with Ankle joint mobilizations	Task-specific training	Range of motion	+
Task-specific training with Ankle joint mobilizations	Task-specific training	Biomechanical gait measures	–
Task-specific training with Ankle joint mobilizations	Task-specific training	Biomechanical balance measures, functional mobility	=
Botulinum toxin A (500U) with functional electrical stimulation	Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching	Biomechanical gait measures, spasticity, range of motion	–
Lower Limb Robot with Conventional rehab	Daoyin with Lower Limb Robot with Conventional rehab	Motor recovery, activities of daily living, balance	–
Conventional exercises	No treatment	Biomechanical balance measures	–
Tai Chi	Usual care	Falls and fear of falling	+
SilverSneakers exercises	Usual care	Falls and fear of falling, muscle strength, balance, quality of life	–

Tai Chi	Usual care	Muscle strength, balance, quality of life	–
Ankle Kinesio taping	No Taping	Biomechanical gait measures, range of motion, gait speed	+
Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (PNF-KT)	No Taping	Biomechanical gait measures, range of motion, gait speed	+

Orthotic Devices

Adopted from: https://unsplash.com/

Orthotics are defined as medical devices used to improve the function and mobility of the body. Commonly used orthotics used in post-stroke rehabilitation of the lower extremity include ankle foot orthoses and shoe lifts. Shoe lifts or wedges alter biomechanical positioning by compelling a weight shift to the paretic side and consequently redistribute weight more symmetrically. This has the potential to improve the ability for functional ambulation and quality gait cycles. Ankle-foot orthotics (also known as foot-drop splints) aim to stabilize the foot and ankle and during weight- bearing and lift the toes while stepping, in effect reducing foot drop (Tyson & Kent, 2013). Other assistive devices including taping and canes are also reviewed below.

A total of 82 RCTs were found that evaluated orthotic devices for lower extremity motor rehabilitation. Eighteen RCTs evaluated taping interventions (Gup et al. 2024; Jung et al. 2024; Moon et al. 2024; Hosbas et al. 2023; Wang et al. 2022c; Cho et al. 2022b; Jung et al. 2022; In et al. 2021b; Kurul et al. 2021; Mehraein et al. 2021; Cho et al. 2020b; Choi et al. 2020b; Park et al. 2020a; Chen et al. 2019c; Shin et al. 2019; Sheng et al. 2019; Kim & Kang 2018; Maguire et al. 2010). Two RCTs compared Taping With Electrical Stimulation with Electrical Stimulation or Taping Alone or No Taping (Bae et al. 2022; In et al. 2021b). One RCT compared New Body Orthosis with No Orthosis (Thijssen et al. 2007). Five RCTs compared Shoe Insole Orthotics During Walking with Overground Walking or Conventional Therapy or Sham (Liu et al. 2021a; Liao et al. 2018; Ferreira et al. 2017; Sungkarat 2011; Eckhardt et al. 2011). Two RCTs compared Weight-Shift Therapy Using Shoe Insert with Conventional Treatment (Sheikh et al. 2016; Aruin et al. 2012). Ten RCTs compared Ankle-Foot Orthosis with No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis (Rimaud et al. 2024; Karpe et al. 2019; Yeung et al. 2018; Pomeroy et al. 2016; Zissimopoulos et al. 2015; Lee et al. 2014c; Erel et al. 2011; Chen et al. 2010; Simons et al. 2009; de Wit et al. 2004). One RCT compared Ankle-Foot Orthosis with Botulinum Toxin with Botulinum Toxin (Farina et al. 2008). One RCT compared Taping with Botulinum Toxin with Botulinum Toxin (Reiter et al. 1998). One RCT compared Early Ankle Foot Orthosis with Late Ankle Foot Orthosis (Nikamp et al. 2017). Sixteen RCTs evaluated A Comparison of Orthoses (Pradhan et al. 2024; Msechu et al. 2023; Ling et al. 2023; Daryabor et al. 2022; Yamamoto et al. 2022; Daryabor et al. 2021; Karakkattil et al. 2020; Katsuhira et al. 2018; Tyson et al. 2018; Yamamoto et al. 2018; Zollo et al. 2015; Do et al. 2014; Rao et al. 2014; de Seze et al. 2011; Forghany et al. 2010; Tyson & Rogerson 2009). Two RCTs compared Anterior Ankle-Foot Orthosis with Posterior Ankle-Foot Orthosis (Chen et al. 2022; Chen et al. 2010). One RCT compared Bivalve Cast with Pressure-Relieving Ankle-Foot Orthosis vs Conventional Care (DeMeyer et al. 2015). One RCT compared Toe Spreader with Conventional Care (Chiong et al. 2013). Three RCTs evaluated Comparing Types of Canes (Huang et al. 2022b; Avelino et al. 2021; Jeong et al. 2015). One RCT compared NMES Orthosis with Ankle-Foot Orthosis (Morone et al. 2012b). One RCT compared

Ankle-Foot Orthosis + Balance Training Shoes with Ankle-Foot Orthosis + Regular Shoes (Farmani et al. 2016). One RCT compared Night Splint with Standing on a Tilt Table (Robinson et al. 2008). Three RCTs compared Arm Sling with No Therapy (Morone et al. 2024; Jeong et al. 2017; Yavuzer & Ergin 2002). Three RCTs compared Wearable Devices with Conventional Care or No Therapy (Ho et al. 2024; Lee et al. 2017b; Pomeroy et al. 2001). One RCT evaluated Standing Frame Assistive Device (Bagley et al. 2005). Two RCTs compared Treadmill Training with Orthotic Devices with Treadmill Training Alone (An et al. 2020; In et al. 2017). One RCT compared Visual Biofeedback with Orthotic Devices with Sham Feedback (Tamburella et al. 2017). One RCT compared Regent Suit with Conventional Therapy (Iuppariello et al. 2018). One RCT compared Knee Immobilizer Brace with Foot Orthosis or Rigid Taping with Knee Immobilizer Brace (Talu & Bazancir 2017). One RCT compared Knee Orthosis with Gait Training with Gait Training Alone (Ito et al. 2024).

In addition, 16 RCTs in which orthotic devices formed part of a combined or comparative intervention are cross-referenced at the end of Table 13; their primary listings appear in other tables.

The methodological details and results of all 82 RCTs are presented in Table 13.

Table 13. RCTs Evaluating Orthotic Devices for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Gup et al. (2024) RCT (6) Nstart=76 Nend=69 TPS=Acute A1 vs A2 vs 0	E1: Anterior Kinesio Taping, E2: Posterior Kinesio Taping C: Standard physiotherapy Duration: 48 hr taping	E1/E2 vs C: TIS (+exp1/2) PASS (+exp1/2) BBS (+exp1/2) FTSST (+exp1/2) E1 vs E2: TIS (+exp1) PASS (+exp1) BBS (-) FTSST (-)
Jung et al. (2024) RCT (6) Nstart=45 Nend=42 TPS=Chronic A1 vs A2 vs 0	E1: Forward Rotation with Posterior Pelvic Tilt Taping; E2: Backward Rotation with Posterior Pelvic Tilt Taping C: Placebo Taping Duration: 1 session	E1 vs E2 vs C: pelvic inclination (+exp) TIS (-) Static Sitting Balance index (-) Dynamic balance (-) Coordination (-) Sway area (-) Sway path length (-) Sway velocity (-) Gait kinetics Velocity (-) cadence (-) step length-affected (+exp) step length-unaffected (+exp) stride length-affected stride length-unaffected single support time-affected Gait symmetry spatial symmetry (-) temporal symmetry (-)
Moon et al. (2024) RCT (6)	E: Floss band around ankle C: Sham band	E vs C: PROM

Nstart=40 Nend=40 TPS=Chronic A vs 0	Duration: 3min, 1x	Dorsiflexion (+exp) Plantarflexion (-) Weight-bearing lunge test (+exp) Static balance sway area (+exp) foot strike (+exp) toe-off (-)
Hosbas et al. (2023) RCT (7) Nstart=30 Nend=30 TPS=Chronic A vs 0	E: Non-elastic ankle taping + conventional physiotherapy C: Conventional physiotherapy Duration: 45min/d, 5d/wk, 4wks	E vs C: Dynamic gait index (-)
Wang et al. (2022c) RCT (6) Nstart=21 Nend=19 TPS=Chronic A vs 0 Also in Table 9 (Treadmill Training); Table 11 (Balance Training); Table 21 (Strength and Resistance Training)	E: Non-elastic taping + Exercise training (progressive resistance exercise, balance training and treadmill training) C: Sham taping + exercise training Duration: 50min/d, 2d/wk, for 6wks	E vs C: double support time (+exp) spatial symmetry index (-) temporal symmetry index (-) velocity (-) BBS (-) 6MWT (-) FES-I (-)
Cho et al. (2022b) RCT (5) Nstart=40 Nend=40 TPS=Chronic A vs B	E1: Extensor Digitorum Longus Taping, E2: Tibialis Anterior Taping Duration: 24 hrs	E1 vs E2: limited stability (-) cadence (-) gait speed (-) stride length (-)
Jung et al. (2022) RCT (6) Nstart=63 Nend=60 TPS=Chronic A + B vs A1 vs A2	E1: Pelvic stability training + posterior and lateral taping E2: Pelvic stability training with posterior taping only C: Pelvic stability training Duration: 30min/d, 5d/wk, 6wks	E1 vs E2: Abductor strength(+exp1) Anterior pelvic tilt(-) Lateral pelvic tilt(+exp1) 10MWT(-) E1 vs C: Abductor strength(+exp1) Anterior pelvic tilt(+exp1) Lateral pelvic tilt(+exp1) 10MWT(+exp1) E2 vs C: Abductor strength(-) Anterior pelvic tilt(+exp2) Lateral pelvic tilt(-) 10MWT(+exp2)
In et al. (2021a) RCT (7) Nstart=40 Nend=40 TPS=Chronic A + B + C + D vs E + C + D	E: Posterior pelvic tilt taping + functional movements (sitting-to- standing + indoor walking + stair walking training) C: Functional movements (sitting-to-standing + indoor walking + stair walking training) Duration: 30min/d, 5d/wk, 6wks	E vs C: Pelvic inclination (+exp) Isometric muscle strength (+exp) 10-metre walk test (+exp)
Kurul et al. (2021) RCT (5) Nstart=68	E: Kinesio taping + conventional therapy C: Conventional therapy Duration: 60min/d, 5d/wk, 2wks	E vs C: Balance Evaluation Systems Test (+exp) Functional Reach Test (+exp)

Nend=61 TPS=Chronic A vs 0		Timed Up and Go Test (-) Tetrax Balance System (postural stability & static balance) (-) Barthel Index (-)

Avelino et al. (2021) RCT (8) Nstart=50 Nend=45 TPS=Chronic A vs B	E: Provision of a single-point cane C: Stretching exercises Duration: 1mo	E vs C: 10-m Walk Test (-) Step length (-) Cadence (-) Six-minute Walk test (-) Modified Gait-Efficacy Scale (-) Stroke Impact Scale (-)
Jeong et al. (2015) RCT crossover (7) Nstart=30 Nend=30 TPS=Chronic A vs B vs C	E1: Single-point cane E2: Quad cane E3: Hemi-walker Duration: same amount of time for 3 days – 1d washout	E1 vs E2 vs E3: 10m Walk test (+exp1) Heart rate (-) 6min Walk test (+exp1) Energy cost (+exp1) Energy expenditure (+exp1)
NMES vs Ankle-Foot Orthosis		
Morone et al. (2012b) RCT (5) Nstart=20 Nend=20 TPS=Acute A vs B Also in Table 29 (Neuromuscular Electrical Stimulation (NMES))	E: NMES (Walkaide) + walking training + conventional therapy C: Walking training + ankle-foot- orthosis + conventional therapy Duration: 40min/d, 5d/wk, 4wks Walking training with NMES or AFO & 40min/d, 5d/wk, 4wks conventional therapy	E vs C: 10-Metre Walk Test (+exp) Functional Ambulation Classification (+exp) Barthel Index (-) Rivermead Mobility Index (-) Medical Research Council Scale (-) Canadian Neurological Scale (-) Ashworth Scale (-) Manual Muscle Test (-)
Ankle-Foot Orthosis + Balance Training Shoes vs Ankle-Foot Orthosis + Regular Shoes		
Farmani et al. (2016) RCT (4) Nstart=30 Nend=30 TPS=Chronic A1 vs A2	E: Solid Ankle-foot orthosis, then Rocker shoes C: Solid Ankle-foot orthosis, then Regular shoes Duration: Not reported	E vs C: Timed Up-and-Go (+exp) Timed Up Stairs test (-) Timed Downstairs test (-) 10-Meter Walk Test at preferred speed (+exp) Oxygen uptake (+exp)
Night Splint vs Standing on a Tilt Table		
Robinson et al. (2008) RCT (8) Nstart=30 Nend=24	E1: Nighttime splint wearing + Inpatient rehabilitation E2: Standing on a tilt table + Inpatient rehabilitation	E1 vs E2: Maximum passive dorsiflexion (-) Motor Assessment Scale (-)

TPS=Acute A vs B	Duration: 30min/d, 5d/wk, 4wks tilt table; 7d/wk, 4wks Nighttime splint; 5d/wk, 4wks Inpatient rehabilitation	
Arm Sling vs No Therapy		
Morone et al. (2024) Feasibility/pilot RCT (6) Nstart=24 Nend=24 TPS=Chronic A vs B	E: Shoulder brace C: Upper limb observation during walking Duration: Brace: 8 hours/d, 7ds/wk, 4 wks; Conventional neurorehabilitation (Both groups): 1 session/d, 5 ds/wk	E vs C: Trunk control test (+exp) Numerical rating scale Pain (-) Manual Muscle test (-) Motricity Index (-) Stride length (-) Stride duration (-) Walking speed (-) Coefficient of attenuation along the AP axis between pelvis and head (+exp) Magnitude of coefficient of attenuation (+exp) Coefficient of attenuation from pelvis to sternum (-)
Jeong et al. (2017) RCT crossover (6) Nstart=57 Nend=57 TPS=Chronic A vs B	E: Arm multi-support sling while waking with walk aid C: No support while walking with walk aid Duration: 12min, 1session/d, 1d -1hr washout period.	E vs C for those with a single cane Energy cost (+exp) energy expenditure (+exp) 6 minute walking test (+exp) 10 meter walk test (-) Heart rate (-) E vs C for those with a quad cane walk aid: Energy cost (-) energy expenditure (-) 6 minute walking test (-) 10 meter walk test (-) Heart rate (-)
Yavuzer & Ergin (2002) RCT crossover (4) Nstart=31 Nend=31 TPS=Subacute A vs 0	E: Arm sling C: No treatment Duration: Single session	E vs C: Gait Parameters Walking Velocity (+exp) % of Stance Phase Paretic Side (+exp) Step Time (-) Step Length (-) Double Support Time (+exp) Pelvic Excursion Sagittal Plane (+exp) Coronal Plane (+exp) Transverse Plane (+exp) Hip Excursion (-) Knee Excursion (-) Ankle Excursion (-) Peak Vertical Force (+exp)
Wearable Devices vs Conventional Care or No Therapy		
Ho et al. (2024) RCT (8) Nstart=127 Nend=90 TPS=Acute A vs 0	E: WEAR System-assisted Rehabilitation + Conventional therapy C: Conventional therapy Duration: Experimental group: 90 mins/d (60 mins of conventional rehab + 30 mins of WEAR), over 3 days/week, 12 weeks (TOTAL - 90 days); Control group: 90 mins/d, over 3 ds/week, 12 weeks (TOTAL - 90 days);	E vs C: modified Rankin Scale (+exp) BI (+exp) FIM (+exp) BBS (+exp) WMFT- Functional ability scale (+exp)

Lee et al. (2017b) RCT (6) Nstart=23 Nend=23 TPS=Chronic A vs B vs C	E: Wearable tubing assistive walking device (WTAWD) C1: Conventional elastic band orthosis C2: Walking barefoot (no orthosis) Duration: One session	E vs C1/C2: Gait speed (+exp) Cadence (+exp) Step Length (+exp) Stride Length (+exp) Swing Time (-) C1 vs C2: Gait Speed (+exp) Cadence (+exp) Step Length (+exp) Stride Length (+exp) Swing Time (-)
Pomeroy et al. (2001) RCT (7) Nstart=24 Nend=22 TPS=Chronic A vs 0	E: Wearing weighted garments on the paretic side C: No treatment Duration: 7d/wk, for 6wks	E vs C: Berg Balance Scale (-) Step Length Symmetry Index (-) Single Support Time (-) Double Support Time (-) Support Base Width (-) Velocity (-) Cadence (-)
Standing Frame Assistive Device		
Bagley et al. (2005) RCT (8) Nstart=140 Nend=112 TPS=Acute A vs 0	E: Oswestry standing frame treatment C: Usual treatment Duration: 1sessions/d, 14d	E vs C: Rivermead Mobility Index (-) Barthel Index (-) Hospital Anxiety and Depression score (-) Nottingham Extended ADL scale (-) Rivermead Motor assessment (-) Motor assessment scale (-) Trunk Control Test
Treadmill Training with Orthotic Devices Vs Treadmill Training Alone		
An et al. (2020) RCT (5) Nstart=36 Nend=36 TPS=Chronic A1 vs A2 Also in Table 9 (Treadmill Training)	E: Treadmill training using insole on less affected side C: Treadmill training Duration: 30min/d, 5d/wk, for 4wks	E vs C: Functional Gait Assessment (+exp) Figure-of-Eight Walk Test Step (+exp) Time (+exp) 6-Minute Walk Test (+exp) 10-m Walk Test (+exp) Gait Cadence (+exp) Stride Length/ Heigh Ratio (+exp) Stride Length (+exp) Stance Phase Duration (-) Swing Phase Duration (-) Double Support Duration (+exp) Single Support Duration (+exp)
In et al. (2017) RCT (7) Nstart=30 Nend=30 TPS=Chronic A + B vs A Also in Table 9 (Treadmill Training)	E: Treadmill training + Thera- band C: Treadmill training Duration: 30min/d, 5d/wk, 4wks	E vs C: Fugl-meyer Assessment (+exp) Timed Up-and-Go (+exp) 10-Metre Walk Test (+exp) Performance-oriented mobility assessment (+exp) Balance (-) Gait (+exp)

Visual Biofeedback with Orthotic Devices vs Sham Feedback		
Tamburella et al. (2017) RCT (7) Nstart=10 Nend=10 TPS=Subacute A + B vs A + C Also in Table 15 (Biofeedback)	E: Ankle treatment + biomechanical visual biofeedback (using an active sensorized AFO) C: Ankle treatment + an inactive sensorized AFO (sham) Duration: 60min/d, 5d/wk, 6wks	E vs C: Active/passive ankle ROM (-) Modified Ashworth Scale (+exp) Coactivation index (+exp) Active joint speed (+exp) Passive joint speed (-)
Regent Suit vs Conventional Therapy		
Iuppariello et al. (2018) RCT (4) Nstart=60 Nend=60 TPS=Chronic A vs 0 vs B	E: Rehabilitation training + regent suit C1: Rehabilitation training C2: Healthy controls Duration: 40min/d, 5d/wk for 8wks	E vs C1: NIH Stroke Scale (No stats) Barthel Index (No stats) Functional Independent Measure (No stats) Berg Balance Scale (No stats) EMG patterns SL NAS (+exp) SL AS (+exp) TA NAS (-) TA AS (+exp) ST NAS (+exp) ST AS (+exp) VL NAS (+exp) VL AS (+exp) E vs C2: EMG patterns (-)
Knee Immobilizer Brace with Foot Orthosis or Rigid Taping vs Knee Immobilizer Brace		
Talu & Bazancir (2017) RCT (5) Nstart=20 Nend=20 TPS=Acute A vs A + B vs A + C	E1: Knee immobilizer brace E2: Knee immobilizer brace + Foot lifter orthosis E3: Knee immobilizer brace + Rigid taping Duration: Single application of each intervention	E1 vs E2: Total Balance Score (+exp2) E1 vs E3: Total Balance Score (-) E2 vs E3: Total Balance Score (+exp2)
Knee Orthosis with Gait Training vs Gait Training Alone		
Ito et al. (2024) RCT (6) Nstart=34 Nend=29 TPS=Acute A vs 0	E: Walking Training + Knee Orthosis C: Walking Training Duration: 30 min, 5 d/wk, for 3 wks	E vs C: Trailing Limb Angle (knee kinetic) (+exp) 10MWT (-)
Additional Comparisons from the Source Dataset		
Aruin et al. (2018) RCT (4) Nstart=10 Nend=10 TPS=Chronic A vs 0	E: Physical Therapy Wearing Insole (unaffected side) C: Physical Therapy Duration: 60min, 3d/wk, 6wks	E vs C: Gait Velocity (No stats) Activities-Specific Balance Confidence (No stats) Fugl-Meyer Lower extremity score (No stats) Timed-Up and Go (No stats) Wight Bearing affected (no stats unaffected (No stats) Gait Cycle

		swing phase (No stats) stance phase (No stats) single leg support (No stats)
Han et al. (2011) RCT crossover (6) Nstart=37 Nend=37 TPS=Chronic A vs 0	E: Arm sling C: No Treatment Duration: 20 minute washout	E vs C: Heart rate (+exp) Gait speed (+exp) O2 rate (+exp) O2 cost (+exp)
Suat et al. (2011) RCT (6) Nstart=19 Nend=19 TPS=Chronic A vs 0	E: wearing an Inhibitor Hand Splint during ambulation C: no treatment Duration: 120min/d, 24wks	E vs C: Berg Balance Scale (-) Functional Reach test (-) Timed Up & Go test (+exp) L test (modified version of TUG) (-)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Park et al. (2024a) RCT crossover (6) Nstart=36 Nend=36 TPS=Chronic A + B vs A Primary listing: Table 7 (Non-Technological Overground Walking and Gait Training)	E: Gait training (with insole on non-paretic foot) C: Gait training (without insole) Duration: 10-20min (+5 min practice walking), experiment conducted 1x/participant	E vs C: gait parameters step count (-) step velocity (+exp) cadence (-) step-time differential (+exp) step length differential (-) step time (+exp) step length (+exp) cycle time (-) stride length (-) H-H Base Support (+exp) stride velocity (+exp) Gait cycle swing phase (+exp) stance phase (+exp) single support time (-) double support time (-) Double Support Unload Phase (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Weight-Shift Therapy Using Shoe Insert may not have a difference in efficacy when compared to Conventional Treatment for improving motor recovery.	1	Aruin et al. 2012
2	Ankle-Foot Orthosis may produce greater improvements in motor recovery than No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis.	1	Yeung et al. 2018
2	Neuromuscular electrical stimulation Orthosis may not have a difference in efficacy when compared to Ankle-Foot Orthosis for improving motor recovery.	1	Morone et al. 2012b
1b	Oswestry standing frame treatment may not have a difference in efficacy when compared to Usual treatment for improving motor recovery.	1	Bagley et al. 2005
1b	Treadmill Training with Orthotic Devices may produce greater improvements in motor recovery than Treadmill Training Alone.	1	In et al. 2017
2	Regent Suit may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	1	Iuppariello et al. 2018
2	Physical Therapy Wearing Insole (unaffected side) may not have a difference in efficacy when compared to Physical Therapy for improving motor recovery.	1	Aruin et al. 2018
1b	Robot-assisted gait training (Welwalk orthosis-type robotic leg) with Conventional rehab may not have a difference in efficacy when compared to Conventional rehab for improving motor recovery.	1	Hirano et al. 2024
1b	Bicephalic transcranial direct current stimulation with gait training and foot drop stimulator (Walkaide orthosis) may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with gait training and foot drop stimulator for improving motor recovery.	1	da Cunha et al. 2024
2	There is conflicting evidence about the effect of Botulinum toxin A under ultrasound guidance with ankle foot orthosis (ankle-foot orthosis) and Conventional rehabilitation when compared to Conventional rehabilitation for improving motor recovery.	1	Ding et al. 2015
1b	Tibial nerve block through thermocoagulation with ankle-foot orthosis may not have a difference in efficacy when compared to Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis for improving motor recovery.	1	Beckerman et al. 1996a

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Taping when compared to no taping, sham taping, or conventional therapy for improving biomechanical gait measures.	7	Jung et al. 2024; Moon et al. 2024; Wang et al. 2022c; Jung et al. 2022; Choi et al. 2020b; Shin et al. 2019; Sheng et al. 2019
2	Extensor Digitorum Longus Taping may not have a difference in efficacy when compared to Tibialis Anterior Taping for improving biomechanical gait measures.	1	Cho et al. 2022b
1b	There is conflicting evidence about the effect of Pelvic stability training with posterior and lateral taping when compared to Pelvic	1	Jung et al. 2022

	stability training with posterior taping only for improving biomechanical gait measures.		
1b	Posterior pelvic tilt taping with functional movements (sitting-to-standing, indoor walking and stair walking training) may produce greater improvements in biomechanical gait measures than Functional movements (sitting-to-standing with indoor walking and stair walking training).	1	In et al. 2021a
2	Ankle Kinesio taping may result in lesser improvements in biomechanical gait measures when compared to Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (proprioceptive neuromuscular facilitation-KT).	1	Bae et al. 2022
2	Ankle Kinesio taping or Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (PNF-KT) may produce greater improvements in biomechanical gait measures than No Taping.	1	Bae et al. 2022
2	New Body Orthosis may produce greater improvements in biomechanical gait measures than No Orthosis.	1	Thijssen et al. 2007
1b	Shoe Insole Orthotics During Walking may not have a difference in efficacy when compared to Overground Walking or Conventional Therapy or Sham for improving biomechanical gait measures.	2	Sungkarat 2011; Eckhardt et al. 2011
1b	Weight-Shift Therapy Using Shoe Insert may not have a difference in efficacy when compared to Conventional Treatment for improving biomechanical gait measures.	2	Sheikh et al. 2016; Aruin et al. 2012
1a	Ankle-Foot Orthosis may not have a difference in efficacy when compared to No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis for improving biomechanical gait measures.	5	Rimaud et al. 2024; Yeung et al. 2018; Pomeroy et al. 2016; Zissimopoulos et al. 2015; Chen et al. 2010
1b	C-AFO ("off the shelf" composite AFO) may not have a difference in efficacy when compared to P-AFO (custom made plastic AFO) for improving biomechanical gait measures.	1	Rimaud et al. 2024
1b	C-AFO ("off the shelf" composite AFO) or P-AFO (custom made plastic AFO) may produce greater improvements in biomechanical gait measures than No treatment (No AFO, shoes only).	1	Rimaud et al. 2024
2	Ankle-Foot Orthosis with Botulinum Toxin may produce greater improvements in biomechanical gait measures than Botulinum Toxin.	1	Farina et al. 2008
2	Taping with Botulinum Toxin may not have a difference in efficacy when compared to Botulinum Toxin for improving biomechanical gait measures.	1	Reiter et al. 1998
1b	High PFR DAFO may not have a difference in efficacy when compared to Medium PFR DAFO or Low PFR Dynamic Ankle-Foot Orthosis (DAFO) for improving biomechanical gait measures.	1	Pradhan et al. 2024
1b	Low PFR Dynamic Ankle-Foot Orthosis (DAFO) may not have a difference in efficacy when compared to Medium PFR DAFO for improving biomechanical gait measures.	1	Pradhan et al. 2024
1a	There is conflicting evidence about the effect of A Comparison of Orthoses when compared to Oil Damper ankle-foot orthosis with Gait training for improving biomechanical gait measures.	11	Ling et al. 2023; Daryabor et al. 2022; Yamamoto et al. 2022; Daryabor et al. 2021; Tyson et al. 2018; Yamamoto et al. 2018; Katsuhira et al. 2018; Zollo et al. 2015; Rao et al. 2014; Do et al. 2014; Tyson & Rogerson 2009
2	Ankle-foot orthosis-PlfS with shoe (SSh) may not have a difference in efficacy when compared to SSh only for improving biomechanical gait measures.	1	Daryabor et al. 2021

2	AFO-plfR may produce greater improvements in biomechanical gait measures than SSh only.	1	Daryabor et al. 2021
2	AFO-PlfS with Standard shoe (SSh) may not have a difference in efficacy when compared to AFO-plfR for improving biomechanical gait measures.	1	Daryabor et al. 2021
2	There is conflicting evidence about the effect of Ankle-foot orthosis with mechanical plantar flexion stops (ankle-foot orthosis-PlfS) with Rocker shoe (RSh) when compared to ankle-foot orthosis-PlfS with shoe (SSh) for improving biomechanical gait measures.	1	Daryabor et al. 2021
2	Solid Ankle Foot Orthosis may not have a difference in efficacy when compared to Dynamic Ankle Foot Orthosis for improving biomechanical gait measures.	1	Zollo et al. 2015
1b	Plastic ankle foot orthosis made with polypropylene may not have a difference in efficacy when compared to Hybrid ankle foot orthosis made with polypropylene covered with canvas fabric for improving biomechanical gait measures.	1	Do et al. 2014
1b	Plastic ankle foot orthosis made with polypropylene or Hybrid ankle foot orthosis made with polypropylene covered with canvas fabric may not have a difference in efficacy when compared to Barefoot for improving biomechanical gait measures.	1	Do et al. 2014
2	Using an off-the-shelf carbon ankle-foot orthosis (C- ankle-foot orthosis) may produce greater improvements in biomechanical gait measures than Using a custom plastic ankle-foot orthosis (P-ankle-foot orthosis).	1	Rao et al. 2014
2	Using an off-the-shelf carbon ankle-foot orthosis (C- AFO) or Using a custom plastic ankle-foot orthosis (P-AFO) may produce greater improvements in biomechanical gait measures than No ankle-foot orthosis.	1	Rao et al. 2014
2	There is conflicting evidence about the effect of Anterior Ankle-Foot Orthosis when compared to Posterior Ankle-Foot Orthosis for improving biomechanical gait measures.	1	Chen et al. 2010
1b	Toe Spreader may not have a difference in efficacy when compared to Conventional Care for improving biomechanical gait measures.	1	Chiong et al. 2013
1a	Comparing Types of Canes may not have a difference in efficacy when compared to Ambulation therapy with cane with Conventional therapy for improving biomechanical gait measures.	2	Huang et al. 2022b; Avelino et al. 2021
1b	Arm Sling may not have a difference in efficacy when compared to No Therapy for improving biomechanical gait measures.	2	Morone et al. 2024; Yavuzer & Ergin 2002
1a	Wearable Devices may not have a difference in efficacy when compared to Conventional Care or No Therapy for improving biomechanical gait measures.	2	Lee et al. 2017b; Pomeroy et al. 2001
2	Treadmill Training with Orthotic Devices may produce greater improvements in biomechanical gait measures than Treadmill Training Alone.	1	An et al. 2020
1b	Knee Orthosis with Gait Training may produce greater improvements in biomechanical gait measures than Gait Training Alone.	1	Ito et al. 2024
2	Physical Therapy Wearing Insole (unaffected side) may not have a difference in efficacy when compared to Physical Therapy for improving biomechanical gait measures.	1	Aruin et al. 2018
1b	Gait training (with insole on non-paretic foot) may produce greater improvements in biomechanical gait measures than Gait training (without insole).	1	Park et al. 2024a

1b	Shoulder brace during treadmill training may produce greater improvements in biomechanical gait measures than conventional treadmill training.	1	Park et al. 2024b
1b	Ankle foot orthosis with gait training may produce greater improvements in biomechanical gait measures than functional electrical stimulation with gait training.	1	Sannyasi et al. 2022
1b	Botulinum toxin A (500U) with functional electrical stimulation may not have a difference in efficacy when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching for improving biomechanical gait measures.	1	Baricich et al. 2008

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Taping when compared to no taping, sham taping, or conventional therapy for improving biomechanical balance measures.	5	Jung et al. 2024; Moon et al. 2024; Kurul et al. 2021; Cho et al. 2020b; Park et al. 2020a
1a	Shoe Insole Orthotics During Walking may not have a difference in efficacy when compared to Overground Walking or Conventional Therapy or Sham for improving biomechanical balance measures.	2	Liu et al. 2021a; Ferreira et al. 2017
1b	Weight-Shift Therapy Using Shoe Insert may produce greater improvements in biomechanical balance measures than Conventional Treatment.	1	Sheikh et al. 2016
2	Ankle-Foot Orthosis may not have a difference in efficacy when compared to No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis for improving biomechanical balance measures.	2	Lee et al. 2014c; Simons et al. 2009
1b	High PFR DAFO may not have a difference in efficacy when compared to Medium PFR DAFO or Low PFR Dynamic Ankle-Foot Orthosis (DAFO) for improving biomechanical balance measures.	1	Pradhan et al. 2024
1b	Low PFR Dynamic Ankle-Foot Orthosis (DAFO) may not have a difference in efficacy when compared to Medium PFR DAFO for improving biomechanical balance measures.	1	Pradhan et al. 2024
1b	A Comparison of Orthoses may not have a difference in efficacy when compared to Oil Damper ankle-foot orthosis with Gait training for improving biomechanical balance measures.	1	Yamamoto et al. 2018
1b	Unstable board intervention (using AIREX Balance-pad) under non-paralyzed lower leg with Knee ankle foot orthosis (KAFO) on paralyzed leg and Usual physical therapy may produce greater improvements in biomechanical balance measures than Usual Physical Therapy.	1	Nagai et al. 2024

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Pelvic stability training with posterior and lateral taping may produce greater improvements in muscle strength than Pelvic stability training with posterior taping only.	1	Jung et al. 2022
1b	Taping may produce greater improvements in muscle strength than no taping, sham taping, or conventional therapy.	1	Jung et al. 2022
1b	Posterior pelvic tilt taping with functional movements (sitting-to-standing, indoor walking and stair walking training) may produce greater improvements in muscle strength than Functional movements (sitting-to-standing with indoor walking and stair walking training).	1	In et al. 2021a

1b	Taping With Electrical Stimulation may produce greater improvements in muscle strength than Electrical Stimulation or Taping Alone or No Taping.	1	In et al. 2021b
1b	A Comparison of Orthoses may not have a difference in efficacy when compared to Oil Damper ankle-foot orthosis with Gait training for improving muscle strength.	1	de Seze et al. 2011
2	5-degree lateral wedge orthotic in both shoes may not have a difference in efficacy when compared to 8.5-degree lateral wedge orthotic in both shoes for improving muscle strength.	1	Forghany et al. 2010
2	5-degree lateral wedge orthotic in both shoes may not have a difference in efficacy when compared to Overground walking with no wedge for improving muscle strength.	1	Forghany et al. 2010
2	8.5-degree lateral wedge orthotic in both shoes may produce greater improvements in muscle strength than Overground walking with no wedge.	1	Forghany et al. 2010
2	Neuromuscular electrical stimulation Orthosis may not have a difference in efficacy when compared to Ankle-Foot Orthosis for improving muscle strength.	1	Morone et al. 2012b
1b	Arm Sling may not have a difference in efficacy when compared to No Therapy for improving muscle strength.	1	Morone et al. 2024
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may not have a difference in efficacy when compared to Botulinum toxin A (100U) with Taping and stretching and gait training for improving muscle strength.	1	Carda et al. 2011

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Taping may not have a difference in efficacy when compared to no taping, sham taping, or conventional therapy for improving spasticity.	1	Mehraein et al. 2021
1b	Taping With Electrical Stimulation may produce greater improvements in spasticity than Electrical Stimulation or Taping Alone or No Taping.	1	In et al. 2021b
2	Ankle-Foot Orthosis may not have a difference in efficacy when compared to No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis for improving spasticity.	1	Yeung et al. 2018
2	Ankle-Foot Orthosis with Botulinum Toxin may produce greater improvements in spasticity than Botulinum Toxin.	1	Farina et al. 2008
2	Taping with Botulinum Toxin may not have a difference in efficacy when compared to Botulinum Toxin for improving spasticity.	1	Reiter et al. 1998
1b	A Comparison of Orthoses may not have a difference in efficacy when compared to Oil Damper ankle-foot orthosis with Gait training for improving spasticity.	1	de Seze et al. 2011
1b	Bivalve Cast may not have a difference in efficacy when compared to Pressure-Relieving Ankle-Foot Orthosis or Conventional Care for improving spasticity.	1	DeMeyer et al. 2015
1b	Pressure-relieving Ankle- foot Orthosis with Physical Therapy may not have a difference in efficacy when compared to Physical Therapy for improving spasticity.	1	DeMeyer et al. 2015
1b	Toe Spreader may not have a difference in efficacy when compared to Conventional Care for improving spasticity.	1	Chiong et al. 2013

2	Neuromuscular electrical stimulation Orthosis may not have a difference in efficacy when compared to Ankle-Foot Orthosis for improving spasticity.	1	Morone et al. 2012b
1b	Visual Biofeedback with Orthotic Devices may produce greater improvements in spasticity than Sham Feedback.	1	Tamburella et al. 2017
1b	Cryo-airflow therapy for calf muscle with Physical therapy and Ankle foot orthosis at night may produce greater improvements in spasticity than Physical therapy with Ankle foot orthosis.	1	Elnassag et al. 2019
2	There is conflicting evidence about the effect of Botulinum toxin A under ultrasound guidance with ankle foot orthosis (ankle-foot orthosis) and Conventional rehabilitation when compared to Conventional rehabilitation for improving spasticity.	1	Ding et al. 2015
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may produce greater improvements in spasticity than Botulinum toxin A (100U) with Taping and stretching and gait training.	1	Carda et al. 2011
1b	Botulinum toxin A (75- 100U) with Kinesio Taping and home exercises may not have a difference in efficacy when compared to Botulinum toxin A (75- 100U) with Sham taping and home exercises for improving spasticity.	1	Karadag-Saygi et al. 2010
1b	Botulinum toxin A (500U) with functional electrical stimulation may not have a difference in efficacy when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching for improving spasticity.	1	Baricich et al. 2008
1b	Tibial nerve block through thermocoagulation with ankle-foot orthosis may not have a difference in efficacy when compared to Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis for improving spasticity.	1	Beckerman et al. 1996a

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Taping when compared to no taping, sham taping, or conventional therapy for improving range of motion.	1	Moon et al. 2024
2	Ankle Kinesio taping may result in lesser improvements in range of motion when compared to Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (proprioceptive neuromuscular facilitation-KT).	1	Bae et al. 2022
2	Ankle Kinesio taping or Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (PNF-KT) may produce greater improvements in range of motion than No Taping.	1	Bae et al. 2022
2	Shoe Insole Orthotics During Walking may not have a difference in efficacy when compared to Overground Walking or Conventional Therapy or Sham for improving range of motion.	1	Eckhardt et al. 2011
1b	Ankle-Foot Orthosis may not have a difference in efficacy when compared to No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis for improving range of motion.	1	Zissimopoulos et al. 2015
1b	C-AFO ("off the shelf" composite AFO) may not have a difference in efficacy when compared to P-AFO (custom made plastic AFO) for improving range of motion.	1	Rimaud et al. 2024

1b	C-AFO ("off the shelf" composite AFO) or P-AFO (custom made plastic AFO) may produce greater improvements in range of motion than No treatment (No AFO, shoes only).	1	Rimaud et al. 2024
2	Taping with Botulinum Toxin may not have a difference in efficacy when compared to Botulinum Toxin for improving range of motion.	1	Reiter et al. 1998
1b	High PFR DAFO may result in lesser improvements in range of motion when compared to Medium PFR DAFO or Low PFR Dynamic Ankle-Foot Orthosis (DAFO).	1	Pradhan et al. 2024
1b	Low PFR Dynamic Ankle-Foot Orthosis (DAFO) may result in lesser improvements in range of motion when compared to Medium PFR DAFO.	1	Pradhan et al. 2024
1a	There is conflicting evidence about the effect of A Comparison of Orthoses when compared to Oil Damper ankle-foot orthosis with Gait training for improving range of motion.	4	Daryabor et al. 2022; Yamamoto et al. 2022; Katsuhira et al. 2018; Do et al. 2014
2	Ankle-foot orthosis-PlfS with shoe (SSh) may not have a difference in efficacy when compared to SSh only for improving range of motion.	1	Daryabor et al. 2021
2	AFO-plfR may not have a difference in efficacy when compared to SSh only for improving range of motion.	1	Daryabor et al. 2021
2	AFO-PlfS with Standard shoe (SSh) may not have a difference in efficacy when compared to AFO-plfR for improving range of motion.	1	Daryabor et al. 2021
1b	Plastic ankle foot orthosis made with polypropylene may not have a difference in efficacy when compared to Hybrid ankle foot orthosis made with polypropylene covered with canvas fabric for improving range of motion.	1	Do et al. 2014
1b	Anterior ankle foot orthosis may not have a difference in efficacy when compared to Posterior ankle foot orthosis for improving range of motion.	1	Chen et al. 2022
1b	Bivalve Cast may not have a difference in efficacy when compared to Pressure-Relieving Ankle-Foot Orthosis or Conventional Care for improving range of motion.	1	DeMeyer et al. 2015
1b	Pressure-relieving Ankle- foot Orthosis with Physical Therapy may not have a difference in efficacy when compared to Physical Therapy for improving range of motion.	1	DeMeyer et al. 2015
1b	Nighttime splint wearing with Inpatient rehabilitation may not have a difference in efficacy when compared to Standing on a tilt table with Inpatient rehabilitation for improving range of motion.	1	Robinson et al. 2008
1b	Visual Biofeedback with Orthotic Devices may not have a difference in efficacy when compared to Sham Feedback for improving range of motion.	1	Tamburella et al. 2017
1b	Cryo-airflow therapy for calf muscle with Physical therapy and Ankle foot orthosis at night may produce greater improvements in range of motion than Physical therapy with Ankle foot orthosis.	1	Elnassag et al. 2019
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may produce greater improvements in range of motion than Botulinum toxin A (100U) with Taping and stretching and gait training.	1	Carda et al. 2011
1b	Botulinum toxin A (75- 100U) with Kinesio Taping and home exercises may not have a difference in efficacy when compared to Botulinum toxin A (75- 100U) with Sham taping and home exercises for improving range of motion.	1	Karadag-Saygi et al. 2010
1b	Botulinum toxin A (500U) with functional electrical stimulation may not have a difference in efficacy when compared to Botulinum toxin	1	Baricich et al. 2008

	A (500U) with Taping or Botulinum toxin A (500U) and Stretching for improving range of motion.		

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Taping may produce greater improvements in neurophysiological measures than no taping, sham taping, or conventional therapy.	1	Mehraein et al. 2021
2	Walking with TheraTogs may produce greater improvements in neurophysiological measures than Walking with cane at normal height.	1	Maguire et al. 2010
2	There is conflicting evidence about the effect of Walking with hip abductor taping when compared to Walking with cane at normal height for improving neurophysiological measures.	1	Maguire et al. 2010
2	Walking with hip abductor taping may not have a difference in efficacy when compared to Walking with TheraTogs for improving neurophysiological measures.	1	Maguire et al. 2010
2	There is conflicting evidence about the effect of Ankle-Foot Orthosis when compared to No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis for improving neurophysiological measures.	1	Lee et al. 2014c
1b	Anterior ankle foot orthosis may produce greater improvements in neurophysiological measures than Posterior ankle foot orthosis.	1	Chen et al. 2022
2	Regent Suit may produce greater improvements in neurophysiological measures than Conventional Therapy.	1	Iuppariello et al. 2018
1b	Bicephalic transcranial direct current stimulation with gait training and foot drop stimulator (Walkaide orthosis) may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with gait training and foot drop stimulator for improving neurophysiological measures.	1	da Cunha et al. 2024
1b	Cryo-airflow therapy for calf muscle with Physical therapy and Ankle foot orthosis at night may not have a difference in efficacy when compared to Physical therapy with Ankle foot orthosis for improving neurophysiological measures.	1	Elnassag et al. 2019

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Ankle-Foot Orthosis when compared to No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis for improving aerobic measures.	2	Rimaud et al. 2024; Erel et al. 2011
1b	C-AFO ("off the shelf" composite AFO) may not have a difference in efficacy when compared to P-AFO (custom made plastic AFO) for improving aerobic measures.	1	Rimaud et al. 2024
1b	C-AFO ("off the shelf" composite AFO) or P-AFO (custom made plastic AFO) may produce greater improvements in aerobic measures than No treatment (No AFO, shoes only).	1	Rimaud et al. 2024
1b	Single-point cane may produce greater improvements in aerobic measures than Quad cane.	1	Jeong et al. 2015
2	Ankle-Foot Orthosis with Balance Training Shoes may produce greater improvements in aerobic measures than Ankle-Foot Orthosis with Regular Shoes.	1	Farmani et al. 2016
1b	Arm Sling may not have a difference in efficacy when compared to No Therapy for improving aerobic measures.	1	Jeong et al. 2017

1b	Arm sling may produce greater improvements in aerobic measures than No Treatment.	1	Han et al. 2011
1b	Ankle foot orthosis with gait training may not have a difference in efficacy when compared to functional electrical stimulation with gait training for improving aerobic measures.	1	Sannyasi et al. 2022
2	Solid Ankle-foot orthosis, then Rocker shoes may produce greater improvements in aerobic measures than Solid Ankle-foot orthosis, then Regular shoes.	1	Farmani et al. 2016
1b	6wk of Peroneal nerve functional electrical stimulation (WalkAide Foot-Drop Stimulator) followed by 6wk of Ankle Foot Orthosis ; (ankle-foot orthosis) may not have a difference in efficacy when compared to Ankle Foot Orthosis only or 12wk ankle-foot orthosis for improving aerobic measures.	1	Everaert et al. 2013

PAIN			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	A Comparison of Orthoses may not have a difference in efficacy when compared to Oil Damper ankle-foot orthosis with Gait training for improving pain.	1	de Seze et al. 2011
1b	Arm Sling may not have a difference in efficacy when compared to No Therapy for improving pain.	1	Morone et al. 2024

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Taping may not have a difference in efficacy when compared to no taping, sham taping, or conventional therapy for improving activities of daily living.	1	Kurul et al. 2021
1b	Early Ankle Foot Orthosis may produce greater improvements in activities of daily living than Late Ankle Foot Orthosis.	1	Nikamp et al. 2017
1b	A Comparison of Orthoses may not have a difference in efficacy when compared to Oil Damper ankle-foot orthosis with Gait training for improving activities of daily living.	1	de Seze et al. 2011
1b	Bivalve Cast may not have a difference in efficacy when compared to Pressure-Relieving Ankle-Foot Orthosis or Conventional Care for improving activities of daily living.	1	DeMeyer et al. 2015
1b	Pressure-relieving Ankle- foot Orthosis with Physical Therapy may not have a difference in efficacy when compared to Physical Therapy for improving activities of daily living.	1	DeMeyer et al. 2015
1b	Comparing Types of Canes may not have a difference in efficacy when compared to Ambulation therapy with cane with Conventional therapy for improving activities of daily living.	1	Huang et al. 2022b
2	Neuromuscular electrical stimulation Orthosis may not have a difference in efficacy when compared to Ankle-Foot Orthosis for improving activities of daily living.	1	Morone et al. 2012b
1b	Wearable Devices may produce greater improvements in activities of daily living than Conventional Care or No Therapy.	1	Ho et al. 2024
1b	Oswestry standing frame treatment may not have a difference in efficacy when compared to Usual treatment for improving activities of daily living.	1	Bagley et al. 2005

2	Regent Suit may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	1	Iuppariello et al. 2018
1b	Robot-assisted gait training (Welwalk orthosis-type robotic leg) with Conventional rehab may not have a difference in efficacy when compared to Conventional rehab for improving activities of daily living.	1	Hirano et al. 2024
2	There is conflicting evidence about the effect of Botulinum toxin A under ultrasound guidance with ankle foot orthosis (ankle-foot orthosis) and Conventional rehabilitation when compared to Conventional rehabilitation for improving activities of daily living.	1	Ding et al. 2015

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Taping when compared to no taping, sham taping, or conventional therapy for improving gait speed.	6	Jung et al. 2024; Wang et al. 2022c; Jung et al. 2022; Choi et al. 2020b; Chen et al. 2019c; Shin et al. 2019
2	Extensor Digitorum Longus Taping may not have a difference in efficacy when compared to Tibialis Anterior Taping for improving gait speed.	1	Cho et al. 2022b
1b	Pelvic stability training with posterior and lateral taping may not have a difference in efficacy when compared to Pelvic stability training with posterior taping only for improving gait speed.	1	Jung et al. 2022
1b	Posterior pelvic tilt taping with functional movements (sitting-to-standing, indoor walking and stair walking training) may produce greater improvements in gait speed than Functional movements (sitting-to-standing with indoor walking and stair walking training).	1	In et al. 2021a
2	Walking with TheraTogs may not have a difference in efficacy when compared to Walking with cane at normal height for improving gait speed.	1	Maguire et al. 2010
2	Walking with hip abductor taping may not have a difference in efficacy when compared to Walking with cane at normal height for improving gait speed.	1	Maguire et al. 2010
2	Ankle Kinesio taping may result in lesser improvements in gait speed when compared to Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (proprioceptive neuromuscular facilitation-KT).	1	Bae et al. 2022

1a	Arm Sling may not have a difference in efficacy when compared to No Therapy for improving gait speed.	3	Morone et al. 2024; Jeong et al. 2017; Yavuzer & Ergin 2002
1a	There is conflicting evidence about the effect of Wearable Devices when compared to Conventional Care or No Therapy for improving gait speed.	2	Lee et al. 2017b; Pomeroy et al. 2001
1b	Treadmill Training with Orthotic Devices may produce greater improvements in gait speed than Treadmill Training Alone.	2	An et al. 2020; In et al. 2017
1b	There is conflicting evidence about the effect of Visual Biofeedback with Orthotic Devices when compared to Sham Feedback for improving gait speed.	1	Tamburella et al. 2017
1b	Knee Orthosis with Gait Training may not have a difference in efficacy when compared to Gait Training Alone for improving gait speed.	1	Ito et al. 2024
2	Physical Therapy Wearing Insole (unaffected side) may not have a difference in efficacy when compared to Physical Therapy for improving gait speed.	1	Aruin et al. 2018
1b	Arm sling may produce greater improvements in gait speed than No Treatment.	1	Han et al. 2011
1b	Gait training (with insole on non-paretic foot) may produce greater improvements in gait speed than Gait training (without insole).	1	Park et al. 2024a
1b	Shoulder brace during treadmill training may produce greater improvements in gait speed than conventional treadmill training.	1	Park et al. 2024b
1b	Robot-assisted gait training (Welwalk orthosis-type robotic leg) with Conventional rehab may not have a difference in efficacy when compared to Conventional rehab for improving gait speed.	1	Hirano et al. 2024
1b	Ankle foot orthosis with gait training may produce greater improvements in gait speed than functional electrical stimulation with gait training.	1	Sannyasi et al. 2022
2	Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may produce greater improvements in gait speed than Sham taping with treadmill training.	1	Kim & Kang 2018c
2	Solid Ankle-foot orthosis, then Rocker shoes may produce greater improvements in gait speed than Solid Ankle-foot orthosis, then Regular shoes.	1	Farmani et al. 2016
1b	Gait training with robotic leg brace may not have a difference in efficacy when compared to Group exercise without robotic leg brace for improving gait speed.	1	Stein et al. 2014

1b	6wk of Peroneal nerve functional electrical stimulation (WalkAide Foot-Drop Stimulator) followed by 6wk of Ankle Foot Orthosis ; (ankle-foot orthosis) may not have a difference in efficacy when compared to Ankle Foot Orthosis only or 12wk ankle-foot orthosis for improving gait speed.	1	Everaert et al. 2013
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may not have a difference in efficacy when compared to Botulinum toxin A (100U) with Taping and stretching and gait training for improving gait speed.	1	Carda et al. 2011
1b	Botulinum toxin A (75- 100U) with Kinesio Taping and home exercises may not have a difference in efficacy when compared to Botulinum toxin A (75- 100U) with Sham taping and home exercises for improving gait speed.	1	Karadag-Saygi et al. 2010
1b	Tibial nerve block through thermocoagulation with ankle-foot orthosis may not have a difference in efficacy when compared to Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis for improving gait speed.	1	Beckerman et al. 1996a

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Taping when compared to no taping, sham taping, or conventional therapy for improving gait endurance.	2	Wang et al. 2022c; Chen et al. 2019c
2	Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may produce greater improvements in gait endurance than Sham taping with treadmill training.	1	Kim & Kang 2018c
1b	Ankle-Foot Orthosis may not have a difference in efficacy when compared to No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis for improving gait endurance.	2	Rimaud et al. 2024; Yeung et al. 2018
1b	C-AFO ("off the shelf" composite AFO) may not have a difference in efficacy when compared to P-AFO (custom made plastic AFO) for improving gait endurance.	1	Rimaud et al. 2024
1b	C-AFO ("off the shelf" composite AFO) or P-AFO (custom made plastic AFO) may produce greater improvements in gait endurance than No treatment (No AFO, shoes only).	1	Rimaud et al. 2024
1b	Early Ankle Foot Orthosis may not have a difference in efficacy when compared to Late Ankle Foot Orthosis for improving gait endurance.	1	Nikamp et al. 2017
2	A Comparison of Orthoses may not have a difference in efficacy when compared to Oil Damper ankle-foot orthosis with Gait training for improving gait endurance.	1	Karakkattil et al. 2020
1b	Comparing Types of Canes may not have a difference in efficacy when compared to Ambulation therapy with cane with Conventional therapy for improving gait endurance.	1	Avelino et al. 2021
1b	Single-point cane may produce greater improvements in gait endurance than Quad cane.	1	Jeong et al. 2015
1b	There is conflicting evidence about the effect of Arm Sling when compared to No Therapy for improving gait endurance.	1	Jeong et al. 2017
2	Treadmill Training with Orthotic Devices may produce greater improvements in gait endurance than Treadmill Training Alone.	1	An et al. 2020
1b	Gait training (with insole on non-paretic foot) may not have a difference in efficacy when compared to Gait training (without insole) for improving gait endurance.	1	Park et al. 2024a

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Taping may not have a difference in efficacy when compared to no taping, sham taping, or conventional therapy for improving falls and fear of falling.	2	Wang et al. 2022c; Chen et al. 2019c
1b	A Comparison of Orthoses may not have a difference in efficacy when compared to Oil Damper ankle-foot orthosis with Gait training for improving falls and fear of falling.	1	Tyson et al. 2018
2	Physical Therapy Wearing Insole (unaffected side) may not have a difference in efficacy when compared to Physical Therapy for improving falls and fear of falling.	1	Aruin et al. 2018

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Comparing Types of Canes may not have a difference in efficacy when compared to Ambulation therapy with cane with Conventional therapy for improving quality of life.	1	Avelino et al. 2021
1b	Tibial nerve block through thermocoagulation with ankle-foot orthosis may not have a difference in efficacy when compared to Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis for improving quality of life.	1	Beckerman et al. 1996a

Other Associated Outcome Measures

MOOD			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Oswestry standing frame treatment may not have a difference in efficacy when compared to Usual treatment for improving mood.	1	Bagley et al. 2005

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Shoulder brace during treadmill training may produce greater improvements in upper extremity function than conventional treadmill training.	1	Park et al. 2024b

Key Points

- Anterior Kinesio Taping may be beneficial for improving balance, but not functional mobility, after stroke when compared to Posterior Kinesio Taping.
- Taping may be beneficial for improving muscle strength and neurophysiological measures, but not falls and fear of falling, activities of daily living, and spasticity, after stroke when compared to no taping, sham taping, or conventional therapy; the literature is mixed regarding biomechanical balance measures, gait speed, balance, biomechanical gait measures, range of motion, functional mobility, and gait endurance.
- Extensor Digitorum Longus Taping may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Tibialis Anterior Taping.
- Pelvic stability training with posterior and lateral taping may be beneficial for improving muscle strength, but not gait speed, after stroke when compared to Pelvic stability training with posterior taping only; the literature is mixed regarding biomechanical gait measures.

- Posterior pelvic tilt taping with functional movements (sitting-to- standing, indoor walking and stair walking training) may be beneficial for improving biomechanical gait measures, muscle strength, and gait speed after stroke when compared to Functional movements (sitting-to-standing with indoor walking and stair walking training).
- Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may be beneficial for improving gait endurance, functional mobility, and gait speed after stroke when compared to Sham taping with treadmill training.
- Walking with TheraTogs may be beneficial for improving neurophysiological measures, but not gait speed, after stroke when compared to Walking with cane at normal height.
- Walking with hip abductor taping may not be beneficial for improving gait speed after stroke when compared to Walking with cane at normal height; the literature is mixed regarding neurophysiological measures.
- Ankle Kinesio taping may result in lesser improvements in biomechanical gait measures, range of motion, and gait speed when compared to Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (proprioceptive neuromuscular facilitation-KT).
- Taping With Electrical Stimulation may be beneficial for improving muscle strength, spasticity, and gait speed after stroke when compared to Electrical Stimulation or Taping Alone or No Taping.
- New Body Orthosis may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to No Orthosis.
- Shoe Insole Orthotics During Walking may be beneficial for improving functional mobility and balance, but not biomechanical gait measures, biomechanical balance measures, range of motion, and gait speed, after stroke when compared to Overground Walking or Conventional Therapy or Sham.
- Rehabilitation with Balance training and Visual biofeedback may not be beneficial for improving functional mobility and balance after stroke when compared to rehabilitation program with lateral wedge insole.
- Weight-Shift Therapy Using Shoe Insert may be beneficial for improving biomechanical balance measures, but not motor recovery, biomechanical gait measures, gait speed, and balance, after stroke when compared to Conventional Treatment.
- Ankle-Foot Orthosis may be beneficial for improving motor recovery and functional mobility, but not biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, gait speed, gait endurance, and balance, after stroke when compared to No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis; the literature is mixed regarding neurophysiological measures and aerobic measures.
- Ankle-Foot Orthosis with Botulinum Toxin may be beneficial for improving biomechanical gait measures and spasticity, but not gait speed, after stroke when compared to Botulinum Toxin.
- Taping with Botulinum Toxin may not be beneficial for improving biomechanical gait measures, spasticity, range of motion, and gait speed after stroke when compared to Botulinum Toxin.
- Early Ankle Foot Orthosis may be beneficial for improving activities of daily living and balance, but not gait speed, gait endurance, and functional mobility, after stroke when compared to Late Ankle Foot Orthosis.
- High PFR DAFO may not be beneficial for improving biomechanical gait measures and biomechanical balance measures after stroke when compared to Medium PFR DAFO or Low PFR Dynamic Ankle-Foot Orthosis (DAFO); High PFR DAFO may result in lesser improvements in range of motion and gait speed when compared to Medium PFR DAFO or Low PFR Dynamic Ankle-Foot Orthosis (DAFO).
- Low PFR Dynamic Ankle-Foot Orthosis (DAFO) may not be beneficial for improving biomechanical gait measures and biomechanical balance measures after stroke when compared to Medium PFR DAFO; Low PFR Dynamic Ankle-Foot Orthosis (DAFO) may result in lesser improvements in range of motion and gait speed when compared to Medium PFR DAFO.
- Carbon composite ankle-foot orthosis may not be beneficial for improving gait speed and functional mobility after stroke when compared to Posterior leaf spring ankle-foot orthosis.
- A Comparison of Orthoses may not be beneficial for improving biomechanical balance measures, muscle strength, spasticity, pain, activities of daily living, gait endurance, functional mobility, balance, and falls and fear of falling after stroke when compared to Oil Damper ankle-foot orthosis with Gait training; the literature is mixed regarding biomechanical gait measures, range of motion, and gait speed.

- Ankle-foot orthosis-PlfS with shoe (SSh) may not be beneficial for improving biomechanical gait measures and range of motion after stroke when compared to SSh only.
- AFO-plfR may be beneficial for improving biomechanical gait measures, but not range of motion, after stroke when compared to SSh only.
- AFO-PlfS with Standard shoe (SSh) may not be beneficial for improving biomechanical gait measures and range of motion after stroke when compared to AFO-plfR.
- The literature is mixed regarding the effect of Ankle-foot orthosis with mechanical plantar flexion stops (ankle-foot orthosis-PlfS) with Rocker shoe (RSh) on biomechanical gait measures after stroke when compared to ankle-foot orthosis-PlfS with shoe (SSh).
- Solid Ankle Foot Orthosis may not be beneficial for improving biomechanical gait measures after stroke when compared to Dynamic Ankle Foot Orthosis.
- Plastic ankle foot orthosis made with polypropylene may not be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to Hybrid ankle foot orthosis made with polypropylene covered with canvas fabric.
- Using an off-the-shelf carbon ankle-foot orthosis (C- ankle-foot orthosis) may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Using a custom plastic ankle-foot orthosis (P-ankle-foot orthosis).
- 5-degree lateral wedge orthotic in both shoes may not be beneficial for improving muscle strength and gait speed after stroke when compared to 8.5-degree lateral wedge orthotic in both shoes.
- Anterior ankle foot orthosis may be beneficial for improving neurophysiological measures, but not range of motion, after stroke when compared to Posterior ankle foot orthosis; the literature is mixed regarding gait speed and biomechanical gait measures.
- Bivalve Cast may not be beneficial for improving spasticity, range of motion, and activities of daily living after stroke when compared to Pressure-Relieving Ankle-Foot Orthosis or Conventional Care.
- Toe Spreader may not be beneficial for improving biomechanical gait measures, spasticity, gait speed, and balance after stroke when compared to Conventional Care.
- Comparing Types of Canes may not be beneficial for improving biomechanical gait measures, activities of daily living, gait speed, functional mobility, balance, gait endurance, and quality of life after stroke when compared to Ambulation therapy with cane with Conventional therapy.
- Single-point cane may be beneficial for improving aerobic measures, gait speed, and gait endurance after stroke when compared to Quad cane.
- Neuromuscular electrical stimulation Orthosis may be beneficial for improving gait speed, but not motor recovery, muscle strength, spasticity, and activities of daily living, after stroke when compared to Ankle-Foot Orthosis; the literature is mixed regarding functional mobility.
- Ankle-Foot Orthosis with Balance Training Shoes may be beneficial for improving aerobic measures and gait speed, but not functional mobility, after stroke when compared to Ankle-Foot Orthosis with Regular Shoes.
- Nighttime splint wearing with Inpatient rehabilitation may not be beneficial for improving range of motion and functional mobility after stroke when compared to Standing on a tilt table with Inpatient rehabilitation.
- Arm Sling may be beneficial for improving balance, but not biomechanical gait measures, muscle strength, aerobic measures, pain, and gait speed, after stroke when compared to No Therapy; the literature is mixed regarding gait endurance.
- Wearable Devices may be beneficial for improving activities of daily living and balance, but not biomechanical gait measures, after stroke when compared to Conventional Care or No Therapy; the literature is mixed regarding gait speed.
- Oswestry standing frame treatment may not be beneficial for improving motor recovery, activities of daily living, and functional mobility after stroke when compared to Usual treatment.
- Treadmill Training with Orthotic Devices may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and motor recovery after stroke when compared to Treadmill Training Alone; the literature is mixed regarding balance.
- Visual Biofeedback with Orthotic Devices may be beneficial for improving spasticity, but not range of motion, after stroke when compared to Sham Feedback; the literature is mixed regarding gait speed.

- Regent Suit may be beneficial for improving neurophysiological measures, but not motor recovery, activities of daily living, and balance, after stroke when compared to Conventional Therapy.
- Knee immobilizer brace may result in lesser improvements in balance when compared to Knee immobilizer brace with Foot lifter orthosis.
- Knee immobilizer brace may not be beneficial for improving balance after stroke when compared to Knee immobilizer brace with Rigid taping.
- Knee immobilizer brace with Foot lifter orthosis may be beneficial for improving balance after stroke when compared to Knee immobilizer brace with Rigid taping.
- Knee Orthosis with Gait Training may be beneficial for improving biomechanical gait measures, but not gait speed, after stroke when compared to Gait Training Alone.
- Physical Therapy Wearing Insole (unaffected side) may not be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and falls and fear of falling after stroke when compared to Physical Therapy.
- Arm sling may be beneficial for improving aerobic measures and gait speed after stroke when compared to No Treatment.
- Wearing an Inhibitor Hand Splint during ambulation may not be beneficial for improving balance after stroke when compared to no treatment; the literature is mixed regarding functional mobility.
- Gait training (with insole on non-paretic foot) may be beneficial for improving biomechanical gait measures and gait speed, but not gait endurance, after stroke when compared to Gait training (without insole).
- Shoulder brace during treadmill training may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to conventional treadmill training.
- Unstable board intervention (using AIREX Balance-pad) under non-paralyzed lower leg with Knee ankle foot orthosis (KAFO) on paralyzed leg and Usual physical therapy may be beneficial for improving biomechanical balance measures after stroke when compared to Usual Physical Therapy.
- Robot-assisted gait training (Welwalk orthosis-type robotic leg) with Conventional rehab may not be beneficial for improving motor recovery, activities of daily living, gait speed, gait endurance, and functional mobility after stroke when compared to Conventional rehab.
- Bicephalic transcranial direct current stimulation with gait training and foot drop stimulator (Walkaide orthosis) may not be beneficial for improving motor recovery, neurophysiological measures, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with gait training and foot drop stimulator.
- Ankle foot orthosis with gait training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility, but not aerobic measures, after stroke when compared to functional electrical stimulation with gait training.
- Cryo-airflow therapy for calf muscle with Physical therapy and Ankle foot orthosis at night may be beneficial for improving spasticity and range of motion, but not neurophysiological measures, after stroke when compared to Physical therapy with Ankle foot orthosis.
- Solid Ankle-foot orthosis, then Rocker shoes may be beneficial for improving aerobic measures and gait speed, but not functional mobility, after stroke when compared to Solid Ankle-foot orthosis, then Regular shoes.
- The literature is mixed regarding the effect of Botulinum toxin A under ultrasound guidance with ankle foot orthosis (ankle-foot orthosis) and Conventional rehabilitation on motor recovery, spasticity, activities of daily living, and balance after stroke when compared to Conventional rehabilitation.
- Gait training with robotic leg brace may not be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Group exercise without robotic leg brace.
- 6wk of Peroneal nerve functional electrical stimulation (WalkAide Foot-Drop Stimulator) followed by 6wk of Ankle Foot Orthosis ; (ankle-foot orthosis) may not be beneficial for improving aerobic measures, gait speed, and functional mobility after stroke when compared to Ankle Foot Orthosis only or 12wk ankle-foot orthosis.
- Botulinum toxin A (100U) with Serial casting and stretching and gait training may be beneficial for improving spasticity and range of motion, but not muscle strength, gait speed, gait endurance, and

functional mobility, after stroke when compared to Botulinum toxin A (100U) with Taping and stretching and gait training.

- Botulinum toxin A (75- 100U) with Kinesio Taping and home exercises may not be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to Botulinum toxin A (75- 100U) with Sham taping and home exercises.
- Botulinum toxin A (500U) with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, spasticity, and range of motion after stroke when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching.
- Odstock Dropped-foot Stimulator (peroneal nerve functional electrical stimulation) may not be beneficial for improving functional mobility after stroke when compared to No Intervention.
- Tibial nerve block through thermocoagulation with ankle-foot orthosis may not be beneficial for improving motor recovery, spasticity, gait speed, and quality of life after stroke when compared to Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis.
- Ankle Kinesio taping may be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to No Taping.
- Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (PNF-KT) may be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to No Taping.
- Anterior Kinesio Taping may be beneficial for improving balance after stroke when compared to Standard physiotherapy.
- Posterior Kinesio Taping may be beneficial for improving balance after stroke when compared to Standard physiotherapy.
- Plastic ankle foot orthosis made with polypropylene may be beneficial for improving gait speed, but not biomechanical gait measures, after stroke when compared to Barefoot.
- Hybrid ankle foot orthosis made with polypropylene covered with canvas fabric may not be beneficial for improving gait speed and biomechanical gait measures after stroke when compared to Barefoot.
- Using an off-the-shelf carbon ankle-foot orthosis (C- AFO) may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to No ankle-foot orthosis.
- Using a custom plastic ankle-foot orthosis (P-AFO) may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to No ankle-foot orthosis.
- 5-degree lateral wedge orthotic in both shoes may not be beneficial for improving muscle strength and gait speed after stroke when compared to Overground walking with no wedge.
- Pressure-relieving Ankle- foot Orthosis with Physical Therapy may not be beneficial for improving spasticity, range of motion, and activities of daily living after stroke when compared to Physical Therapy.
- Customized unilateral ankle-foot orthosis may be beneficial for improving functional mobility after stroke when compared to No Intervention.
- 8.5-degree lateral wedge orthotic in both shoes may be beneficial for improving muscle strength, but not gait speed, after stroke when compared to Overground walking with no wedge.
- Walking with hip abductor taping may not be beneficial for improving neurophysiological measures after stroke when compared to Walking with TheraTogs.
- C-AFO ("off the shelf" composite AFO) or P-AFO (custom made plastic AFO) may be beneficial for improving biomechanical gait measures, range of motion, aerobic measures, gait speed, and gait endurance after stroke when compared to No treatment (No AFO, shoes only).
- C-AFO ("off the shelf" composite AFO) may not be beneficial for improving biomechanical gait measures, range of motion, aerobic measures, gait speed, and gait endurance after stroke when compared to P-AFO (custom made plastic AFO).

Summary of Key Points: Orthotic Devices

Intervention	Control(s)	Function domain(s)	Effect
Anterior Kinesio Taping	Posterior Kinesio Taping	Balance	+

Anterior Kinesio Taping	Posterior Kinesio Taping	Functional mobility	–
Taping	no taping, sham taping, or conventional therapy	Falls and fear of falling, activities of daily living, spasticity	–
Taping	no taping, sham taping, or conventional therapy	Biomechanical gait measures, biomechanical balance measures, gait speed, balance, range of motion, functional mobility, gait endurance	=
Taping	no taping, sham taping, or conventional therapy	Muscle strength, neurophysiological measures	+
Taping	no taping, sham taping, or conventional therapy	Range of motion	=
Taping	no taping, sham taping, or conventional therapy	Falls and fear of falling	–
Extensor Digitorum Longus Taping	Tibialis Anterior Taping	Biomechanical gait measures, gait speed	–
Pelvic stability training with posterior and lateral taping	Pelvic stability training with posterior taping only	Muscle strength	+
Pelvic stability training with posterior and lateral taping	Pelvic stability training with posterior taping only	Gait speed	–
Pelvic stability training with posterior and lateral taping	Pelvic stability training with posterior taping only	Biomechanical gait measures	=
Taping	no taping, sham taping, or conventional therapy	Muscle strength	+
Posterior pelvic tilt taping with functional movements (sitting-to-standing, indoor walking and stair walking training)	Functional movements (sitting-to-standing with indoor walking and stair walking training)	Biomechanical gait measures, muscle strength, gait speed	+
Taping	no taping, sham taping, or conventional therapy	Activities of daily living	–
Taping	no taping, sham taping, or conventional therapy	Neurophysiological measures	+
Taping	no taping, sham taping, or conventional therapy	Spasticity	–
Taping	no taping, sham taping, or conventional therapy	Biomechanical balance measures	=
Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT)	Sham taping with treadmill training	Gait endurance, functional mobility, gait speed	+
Walking with TheraTogs	Walking with cane at normal height	Neurophysiological measures	+
Walking with TheraTogs	Walking with cane at normal height	Gait speed	–
Walking with hip abductor taping	Walking with cane at normal height	Gait speed	–
Walking with hip abductor taping	Walking with cane at normal height	Neurophysiological measures	=
Ankle Kinesio taping	Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping	Biomechanical gait measures, range of motion, gait speed	–

	(proprioceptive neuromuscular facilitation-KT)		
Taping With Electrical Stimulation	Electrical Stimulation or Taping Alone or No Taping	Muscle strength, spasticity, gait speed	+
New Body Orthosis	No Orthosis	Biomechanical gait measures, gait speed	+
Shoe Insole Orthotics During Walking	Overground Walking or Conventional Therapy or Sham	Functional mobility, balance	+
Shoe Insole Orthotics During Walking	Overground Walking or Conventional Therapy or Sham	Biomechanical gait measures, biomechanical balance measures, range of motion, gait speed	–
Rehabilitation with Balance training and Visual biofeedback	rehabilitation program with lateral wedge insole	Functional mobility, balance	–
Weight-Shift Therapy Using Shoe Insert	Conventional Treatment	Biomechanical balance measures	+
Weight-Shift Therapy Using Shoe Insert	Conventional Treatment	Motor recovery, biomechanical gait measures, gait speed, balance	–
Ankle-Foot Orthosis	No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis	Motor recovery, functional mobility	+
Ankle-Foot Orthosis	No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis	Biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, gait speed, gait endurance, balance	–
Ankle-Foot Orthosis	No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis	Neurophysiological measures, aerobic measures	=
Ankle-Foot Orthosis with Botulinum Toxin	Botulinum Toxin	Biomechanical gait measures, spasticity	+
Ankle-Foot Orthosis with Botulinum Toxin	Botulinum Toxin	Gait speed	–
Taping with Botulinum Toxin	Botulinum Toxin	Biomechanical gait measures, spasticity, range of motion, gait speed	–
Early Ankle Foot Orthosis	Late Ankle Foot Orthosis	Gait speed, gait endurance, functional mobility	–
Early Ankle Foot Orthosis	Late Ankle Foot Orthosis	Activities of daily living, balance	+
High PFR DAFO	Medium PFR DAFO or Low PFR Dynamic Ankle-Foot Orthosis (DAFO)	Biomechanical gait measures, biomechanical balance measures, range of motion, gait speed	–
High PFR DAFO	Medium PFR DAFO or Low PFR Dynamic Ankle-Foot Orthosis (DAFO)	Range of motion, gait speed	–
Low PFR Dynamic Ankle-Foot Orthosis (DAFO)	Medium PFR DAFO	Biomechanical gait measures, biomechanical balance measures, range of motion, gait speed	–
Low PFR Dynamic Ankle-Foot Orthosis (DAFO)	Medium PFR DAFO	Range of motion, gait speed	–
Carbon composite ankle-foot orthosis	Posterior leaf spring ankle-foot orthosis	Gait speed, functional mobility	–
A Comparison of Orthoses	Oil Damper ankle-foot orthosis with Gait training	Biomechanical balance measures, muscle strength, spasticity, pain, activities of daily living, gait endurance,	–

		functional mobility, balance, falls and fear of falling	
Ankle-foot orthosis-PlfS with shoe (SSh)	SSh only	Biomechanical gait measures, range of motion	–
AFO-plfR	SSh only	Biomechanical gait measures	+
AFO-plfR	SSh only	Range of motion	–
AFO-PlfS with Standard shoe (SSh)	AFO-plfR	Biomechanical gait measures, range of motion	–
Ankle-foot orthosis with mechanical plantar flexion stops (ankle-foot orthosis-PlfS) with Rocker shoe (RSh)	ankle-foot orthosis-PlfS with shoe (SSh)	Biomechanical gait measures	=
A Comparison of Orthoses	Oil Damper ankle-foot orthosis with Gait training	Gait endurance	–
A Comparison of Orthoses	Oil Damper ankle-foot orthosis with Gait training	Functional mobility, falls and fear of falling	–
A Comparison of Orthoses	Oil Damper ankle-foot orthosis with Gait training	Biomechanical balance measures	–
Solid Ankle Foot Orthosis	Dynamic Ankle Foot Orthosis	Biomechanical gait measures	–
Plastic ankle foot orthosis made with polypropylene	Hybrid ankle foot orthosis made with polypropylene covered with canvas fabric	Biomechanical gait measures, range of motion, gait speed	–
A Comparison of Orthoses	Oil Damper ankle-foot orthosis with Gait training	Biomechanical gait measures, range of motion, gait speed	=
Using an off-the-shelf carbon ankle-foot orthosis (C- ankle-foot orthosis)	Using a custom plastic ankle-foot orthosis (P-ankle-foot orthosis)	Biomechanical gait measures, gait speed	+
A Comparison of Orthoses	Oil Damper ankle-foot orthosis with Gait training	Spasticity, pain, activities of daily living, functional mobility, balance	–
A Comparison of Orthoses	Oil Damper ankle-foot orthosis with Gait training	Gait speed	=
5-degree lateral wedge orthotic in both shoes	8.5-degree lateral wedge orthotic in both shoes	Muscle strength, gait speed	–
Anterior ankle foot orthosis	Posterior ankle foot orthosis	Neurophysiological measures	+
Anterior ankle foot orthosis	Posterior ankle foot orthosis	Range of motion	–
Anterior Ankle-Foot Orthosis	Posterior Ankle-Foot Orthosis	Biomechanical gait measures, gait speed	=
Bivalve Cast	Pressure-Relieving Ankle-Foot Orthosis vs Conventional Care	Spasticity, range of motion, activities of daily living	–
Toe Spreader	Conventional Care	Biomechanical gait measures, spasticity, gait speed, balance	–
Comparing Types of Canes	Ambulation therapy with cane with Conventional therapy	Biomechanical gait measures, activities of daily living, gait speed, functional mobility, balance, gait endurance, quality of life	–
Comparing Types of Canes	Ambulation therapy with cane with Conventional therapy	Biomechanical gait measures, gait speed, gait endurance, functional mobility, quality of life	–

Single-point cane	Quad cane	Aerobic measures, gait speed, gait endurance	+
Neuromuscular electrical stimulation Orthosis	Ankle-Foot Orthosis	Gait speed	+
Neuromuscular electrical stimulation Orthosis	Ankle-Foot Orthosis	Motor recovery, muscle strength, spasticity, activities of daily living	–
Neuromuscular electrical stimulation Orthosis	Ankle-Foot Orthosis	Functional mobility	=
Ankle-Foot Orthosis with Balance Training Shoes	Ankle-Foot Orthosis with Regular Shoes	Aerobic measures, gait speed	+
Ankle-Foot Orthosis with Balance Training Shoes	Ankle-Foot Orthosis with Regular Shoes	Functional mobility	–
Nighttime splint wearing with Inpatient rehabilitation	Standing on a tilt table with Inpatient rehabilitation	Range of motion, functional mobility	–
Arm Sling	No Therapy	Balance	+
Arm Sling	No Therapy	Biomechanical gait measures, muscle strength, aerobic measures, pain, gait speed	–
Arm Sling	No Therapy	Gait endurance	=
Wearable Devices	Conventional Care or No Therapy	Activities of daily living, balance	+
Wearable Devices	Conventional Care or No Therapy	Biomechanical gait measures	–
Wearable Devices	Conventional Care or No Therapy	Gait speed	=
Oswestry standing frame treatment	Usual treatment	Motor recovery, activities of daily living, functional mobility	–
Treadmill Training with Orthotic Devices	Treadmill Training Alone	Biomechanical gait measures, gait speed, gait endurance, functional mobility, motor recovery	+
Treadmill Training with Orthotic Devices	Treadmill Training Alone	Motor recovery, gait speed, functional mobility	+
Treadmill Training with Orthotic Devices	Treadmill Training Alone	Balance	=
Visual Biofeedback with Orthotic Devices	Sham Feedback	Spasticity	+
Visual Biofeedback with Orthotic Devices	Sham Feedback	Range of motion	–
Visual Biofeedback with Orthotic Devices	Sham Feedback	Gait speed	=
Regent Suit	Conventional Therapy	Neurophysiological measures	+
Regent Suit	Conventional Therapy	Motor recovery, activities of daily living, balance	–
Knee immobilizer brace	Knee immobilizer brace with Foot lifter orthosis	Balance	–
Knee immobilizer brace	Knee immobilizer brace with Rigid taping	Balance	–

Knee immobilizer brace with Foot lifter orthosis	Knee immobilizer brace with Rigid taping	Balance	+
Knee Orthosis with Gait Training	Gait Training Alone	Biomechanical gait measures	+
Knee Orthosis with Gait Training	Gait Training Alone	Gait speed	−
Physical Therapy Wearing Insole (unaffected side)	Physical Therapy	Motor recovery, biomechanical gait measures, gait speed, falls and fear of falling	−
Arm sling	No Treatment	Aerobic measures, gait speed	+
Wearing an Inhibitor Hand Splint during ambulation	no treatment	Balance	−
Wearing an Inhibitor Hand Splint during ambulation	no treatment	Functional mobility	=
Gait training (with insole on non-paretic foot)	Gait training (without insole)	Biomechanical gait measures, gait speed	+
Gait training (with insole on non-paretic foot)	Gait training (without insole)	Gait endurance	−
Shoulder brace during treadmill training	conventional treadmill training	Biomechanical gait measures, gait speed	+
Unstable board intervention (using AIREX Balance-pad) under non-paralyzed lower leg with Knee ankle foot orthosis (KAFO) on paralyzed leg and Usual physical therapy	Usual Physical Therapy	Biomechanical balance measures	+
Robot-assisted gait training (Welwalk orthosis-type robotic leg) with Conventional rehab	Conventional rehab	Motor recovery, activities of daily living, gait speed, gait endurance, functional mobility	−
Bicephalic transcranial direct current stimulation with gait training and foot drop stimulator (Walkaide orthosis)	Sham transcranial direct current stimulation with gait training and foot drop stimulator	Motor recovery, neurophysiological measures, functional mobility	−
Ankle foot orthosis with gait training	functional electrical stimulation with gait training	Biomechanical gait measures, gait speed, gait endurance, functional mobility	+
Ankle foot orthosis with gait training	functional electrical stimulation with gait training	Aerobic measures	−
Cryo-airflow therapy for calf muscle with Physical therapy and Ankle foot orthosis at night	Physical therapy with Ankle foot orthosis	Spasticity, range of motion	+
Cryo-airflow therapy for calf muscle with Physical therapy and Ankle foot orthosis at night	Physical therapy with Ankle foot orthosis	Neurophysiological measures	−
Solid Ankle-foot orthosis, then Rocker shoes	Solid Ankle-foot orthosis, then Regular shoes	Aerobic measures, gait speed	+
Solid Ankle-foot orthosis, then Rocker shoes	Solid Ankle-foot orthosis, then Regular shoes	Functional mobility	−
Botulinum toxin A under ultrasound guidance with ankle foot orthosis (ankle-foot orthosis) and Conventional rehabilitation	Conventional rehabilitation	Motor recovery, spasticity, activities of daily living, balance	=

Gait training with robotic leg brace	Group exercise without robotic leg brace	Gait speed, gait endurance, functional mobility, balance	–
6wk of Peroneal nerve functional electrical stimulation (WalkAide Foot-Drop Stimulator) followed by 6wk of Ankle Foot Orthosis ; (ankle-foot orthosis)	Ankle Foot Orthosis only or 12wk ankle-foot orthosis	Aerobic measures, gait speed, functional mobility	–
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with Taping and stretching and gait training	Spasticity, range of motion	+
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with Taping and stretching and gait training	Muscle strength, gait speed, gait endurance, functional mobility	–
Botulinum toxin A (75- 100U) with Kinesio Taping and home exercises	Botulinum toxin A (75- 100U) with Sham taping and home exercises	Spasticity, range of motion, gait speed	–
Botulinum toxin A (500U) with functional electrical stimulation	Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching	Biomechanical gait measures, spasticity, range of motion	–
Odstock Dropped-foot Stimulator (peroneal nerve functional electrical stimulation)	No Intervention	Functional mobility	–
Tibial nerve block through thermocoagulation with ankle-foot orthosis	Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis	Motor recovery, spasticity, gait speed, quality of life	–
Ankle Kinesio taping	No Taping	Biomechanical gait measures, range of motion, gait speed	+
Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (PNF-KT)	No Taping	Biomechanical gait measures, range of motion, gait speed	+
Anterior Kinesio Taping	Standard physiotherapy	Balance	+
Posterior Kinesio Taping	Standard physiotherapy	Balance	+
Plastic ankle foot orthosis made with polypropylene	Barefoot	Gait speed	+
Hybrid ankle foot orthosis made with polypropylene covered with canvas fabric	Barefoot	Gait speed, biomechanical gait measures	–
Plastic ankle foot orthosis made with polypropylene	Barefoot	Biomechanical gait measures	–
Using an off-the-shelf carbon ankle-foot orthosis (C- AFO)	No ankle-foot orthosis	Biomechanical gait measures, gait speed	+
Using a custom plastic ankle-foot orthosis (P-AFO)	No ankle-foot orthosis	Biomechanical gait measures, gait speed	+
5-degree lateral wedge orthotic in both shoes	Overground walking with no wedge	Muscle strength, gait speed	–
8.5-degree lateral wedge orthotic in both shoes	Overground walking with no wedge	Muscle strength	+
Pressure-relieving Ankle- foot Orthosis with Physical Therapy	Physical Therapy	Spasticity, range of motion, activities of daily living	–

Customized unilateral ankle-foot orthosis	No Intervention	Functional mobility	+
8.5-degree lateral wedge orthotic in both shoes	Overground walking with no wedge	Gait speed	–
Walking with hip abductor taping	Walking with TheraTogs	Neurophysiological measures	–
C-AFO ("off the shelf" composite AFO) or P-AFO (custom made plastic AFO)	No treatment (No AFO, shoes only)	Biomechanical gait measures, range of motion, aerobic measures, gait speed, gait endurance	+
C-AFO ("off the shelf" composite AFO)	P-AFO (custom made plastic AFO)	Biomechanical gait measures, range of motion, aerobic measures, gait speed, gait endurance	–

Hippotherapy

Adopted from: https://strokerecoveryfoundation.org

Hippotherapy utilizes the natural gait and rhythmic, repetitive movements of a horse to provide motor and sensory input, such inputs are similar to the movement pattern of the pelvis when a person is walking (Cunningham, 2009; Koca & Ataseven, 2015). As a result, hippotherapy has garnered attention as a rehabilitative method for lower limb stroke recovery.

A total of eight RCTs were found that evaluated hippotherapy for lower extremity motor rehabilitation. Three RCTs compared Hippotherapy Therapy or No Treatment with Conventional Therapy or No Treatment (Ozturk et al. 2024; Kim & Lee 2015c; Sung et al. 2013). One RCT compared Hippotherapy or Rhythm and Music-Based Therapy with No Treatment (Bunketorp-Käll et al. 2017). Two RCTs compared Hippotherapy Training Therapy with Trunk Training Therapy (Coban et al. 2024; Baek et al. 2014). One RCT compared Hippotherapy Training with Treadmill Training (Lee et al. 2014a).

In addition, one RCT in which hippotherapy formed part of a combined or comparative intervention are cross-referenced at the end of Table 14; their primary listings appear in other tables.

The methodological details and results of all eight RCTs are presented in Table 14.

Table 14. RCTs Evaluating Hippotherapy for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score)	Interventions	Outcome Measures Result (direction of effect)

Sample Size start/end Time post stroke category Study design	Duration: Session length, frequency per week for total number of weeks	
Hippotherapy vs Conventional Therapy or No Treatment		
Ozturk et al. (2024) RCT (6) Nstart=26 Nend=26 TPS=Chronic A vs 0	E: Hippotherapy simulator training + Conventional physiotherapy C: Conventional physiotherapy Duration: 60min (15min hippotherapy, 45min CT)/d, 5d/wk, 6wks	E vs C: BBS (+exp) Postural assessment scale for stroke (-) Rivermead mobility index (-) TUG (-) BI (-) 2MWT (+exp)
Kim & Lee (2015c) RCT (4) Nstart=20 Nend=20 TPS=Chronic A vs 0	E: Hippotherapy C: No Treatment Duration: 30min/d, 5d/wk for 6wks	E vs C: 10-Meter Walk Test (+exp) Berg Balance Scale (+exp) Modified Barthel Index (+exp)
Sung et al. (2013) RCT (4) Nstart=20 Nend=20 TPS=Chronic A vs 0	E: Hippotherapy stimulator + conventional rehabilitation C: Conventional rehabilitation Duration: 60min/d, 5d/wk for 4wk	E vs C: Surface EMG during sit to stand (+exp) Step length (-) Stance phase (-) Swing phase (-) Single support (+exp) Load response (+exp) Pre-swing (+exp) Cadence (-) Total double support (+exp)
Hippotherapy or Rhythm and Music-Based Therapy vs No Treatment		
Bunketorp-Käll et al. (2017) RCT (8) Nstart=123 Nend=117 TPS=Chronic A vs B vs 0	E1: Rhythm- and Music-based therapy E2: Horse-riding therapy C: No treatment Duration: 2d/wk, for 12wks	E1/E2 vs C: Stroke Impact Scale (+exp1, +exp2) Timed Up and Go Test (+exp 2) Berg Balance Scale (+exp 2) Bäckstrand, Dahlberg and Liljenäs Balance Scale (+exp1, +exp2) Grip Strength Right Hand Final (-) Right Hand Mean (-) Right Hand Max (+exp1) Left Hand Final (+exp1) Left Hand Mean (-) Left Hand Max (-) Barrow Neurological Institute Screen (+exp1) Letter Number Sequencing (+exp1)
Hippotherapy vs Trunk Training Therapy		
Coban et al. (2024) RCT (5) Nstart=30 Nend=30 TPS=Chronic A vs B	E: Hippotherapy Horseriding simulator therapy + Conventional rehabilitation C: trunk and balance control exercises + conventional rehab Duration: 60min/d(45min conventional, 15min intervention), 5d/wk, 4wks	E vs C: BBS(-) FMA-UE(-) FMA-LE(-) Postural Stability (-) anterior-posterior index (-)

		medial-lateral index (-) Fall Risk Index (-) TIS(-) TUG(-) SF-36(-)
Baek et al. (2014) RCT (3) Nstart=30 Nend=30 TPS=Not reported A + B vs C + B	E: Hippotherapy + Central nervous system development therapy C: Trunk training + Central nervous system development therapy Duration: 1h/d, 3d/wk for 8wks	E vs C: Static Balance (+exp) Muscle Thickness (-)
Hippotherapy vs Treadmill Training		
Lee et al. (2014a) RCT (4) Nstart=30 Nend=30 TPS=Not reported A vs B	E: Hippotherapy C: Treadmill training Duration: 30min/d, 3d/wk for 8wks	E vs C: Step length asymmetry ratio (+exp) Berg Balance Scale (-) Gait speed (+exp)
Additional Comparisons from the Source Dataset		
Bunketorp-Käll et al. (2019) RCT (8) Nstart=123 Nend=117 TPS=Chronic A vs 0	E1: Horse riding therapy; E2: Rhythm-and music based therapy C: Wait list control Duration: 2d/wk, 12wks Hours riding or MT	E1 / E2 vs C: 10 meter walk test time (+exp1) Steps number (+exp1) Step length (-) 6 minute walk test (-) Modified Motor Assessment Scale (+exp1)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Hippotherapy Training Therapy may not have a difference in efficacy when compared to Trunk Training Therapy for improving motor recovery.	1	Coban et al. 2024

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	There is conflicting evidence about the effect of Hippotherapy Therapy or No Treatment when compared to Conventional Therapy or No Treatment for improving biomechanical gait measures.	1	Sung et al. 2013
2	Hippotherapy Training may produce greater improvements in biomechanical gait measures than Treadmill Training.	1	Lee et al. 2014a

1b	Horse riding therapy may produce greater improvements in biomechanical gait measures than Wait list control.	1	Bunketorp-Käll et al. 2019
1b	Rhythm-and music based therapy may not have a difference in efficacy when compared to Wait list control for improving biomechanical gait measures.	1	Bunketorp-Käll et al. 2019

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Hippotherapy Training Therapy may not have a difference in efficacy when compared to Trunk Training Therapy for improving biomechanical balance measures.	1	Coban et al. 2024

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Hippotherapy Training Therapy may not have a difference in efficacy when compared to Trunk Training Therapy for improving muscle strength.	1	Baek et al. 2014

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Hippotherapy Therapy or No Treatment may produce greater improvements in neurophysiological measures than Conventional Therapy or No Treatment.	1	Sung et al. 2013

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Hippotherapy Therapy or No Treatment when compared to Conventional Therapy or No Treatment for improving activities of daily living.	2	Ozturk et al. 2024; Kim & Lee 2015c

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Hippotherapy Therapy or No Treatment may produce greater improvements in gait speed than Conventional Therapy or No Treatment.	1	Kim & Lee 2015c
2	Hippotherapy Training may produce greater improvements in gait speed than Treadmill Training.	1	Lee et al. 2014a
1b	Horse riding therapy may produce greater improvements in gait speed than Wait list control.	1	Bunketorp-Käll et al. 2019
1b	Rhythm-and music based therapy may not have a difference in efficacy when compared to Wait list control for improving gait speed.	1	Bunketorp-Käll et al. 2019

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Hippotherapy Therapy or No Treatment may produce greater improvements in gait endurance than Conventional Therapy or No Treatment.	1	Ozturk et al. 2024

1b	Horse riding therapy or Rhythm-and music based therapy may not have a difference in efficacy when compared to Wait list control for improving gait endurance.	1	Bunketorp-Käll et al. 2019

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Hippotherapy Therapy or No Treatment may not have a difference in efficacy when compared to Conventional Therapy or No Treatment for improving functional mobility.	1	Ozturk et al. 2024
2	Hippotherapy Training Therapy may not have a difference in efficacy when compared to Trunk Training Therapy for improving functional mobility.	1	Coban et al. 2024
1b	Horse riding therapy may produce greater improvements in functional mobility than Wait list control.	1	Bunketorp-Käll et al. 2019
1b	Rhythm-and music based therapy may not have a difference in efficacy when compared to Wait list control for improving functional mobility.	1	Bunketorp-Käll et al. 2019

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Hippotherapy Therapy or No Treatment may produce greater improvements in balance than Conventional Therapy or No Treatment.	2	Ozturk et al. 2024; Kim & Lee 2015c
2	Hippotherapy Training Therapy may not have a difference in efficacy when compared to Trunk Training Therapy for improving balance.	2	Coban et al. 2024; Baek et al. 2014
2	Hippotherapy Training may not have a difference in efficacy when compared to Treadmill Training for improving balance.	1	Lee et al. 2014a

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Hippotherapy Training Therapy may not have a difference in efficacy when compared to Trunk Training Therapy for improving falls and fear of falling.	1	Coban et al. 2024

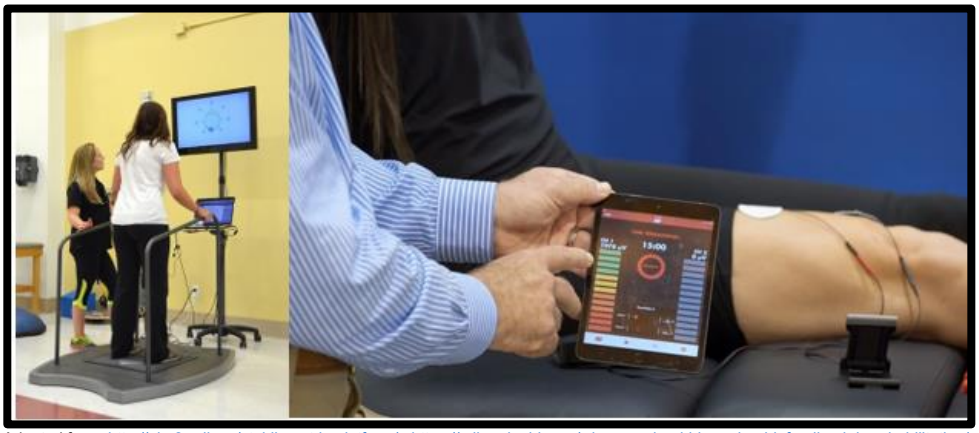
3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Hippotherapy Training Therapy may not have a difference in efficacy when compared to Trunk Training Therapy for improving quality of life.	1	Coban et al. 2024

Other Associated Outcome Measures

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Hippotherapy or Rhythm and Music-Based Therapy when compared to No Treatment for improving upper extremity function.	1	Bunketorp-Käll et al. 2017

2	Hippotherapy Training Therapy may not have a difference in efficacy when compared to Trunk Training Therapy for improving upper extremity function.	1	Coban et al. 2024



Key Points

- Hippotherapy Therapy or No Treatment may be beneficial for improving neurophysiological measures, gait speed, gait endurance, and balance, but not functional mobility, after stroke when compared to Conventional Therapy or No Treatment; the literature is mixed regarding biomechanical gait measures and activities of daily living.
- Hippotherapy Training Therapy may not be beneficial for improving motor recovery, biomechanical balance measures, muscle strength, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Trunk Training Therapy.
- Hippotherapy Training may be beneficial for improving biomechanical gait measures and gait speed, but not balance, after stroke when compared to Treadmill Training.
- Horse riding therapy may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility, but not gait endurance, after stroke when compared to Wait list control.
- Rhythm-and music based therapy may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Wait list control.

Summary of Key Points: Hippotherapy

Intervention	Control(s)	Function domain(s)	Effect
Hippotherapy Therapy or No Treatment	Conventional Therapy or No Treatment	Neurophysiological measures, gait speed, gait endurance, balance	+
Hippotherapy Therapy or No Treatment	Conventional Therapy or No Treatment	Functional mobility	–
Hippotherapy Therapy or No Treatment	Conventional Therapy or No Treatment	Biomechanical gait measures, activities of daily living	=
Hippotherapy Training Therapy	Trunk Training Therapy	Motor recovery, biomechanical balance measures, muscle strength, functional mobility, balance, falls and fear of falling, quality of life	–
Hippotherapy Training	Treadmill Training	Biomechanical gait measures, gait speed	+
Hippotherapy Training	Treadmill Training	Balance	–
Horse riding therapy	Wait list control	Biomechanical gait measures, gait speed, functional mobility	+
Horse riding therapy	Wait list control	Gait endurance	–
Rhythm-and music based therapy	Wait list control	Biomechanical gait measures, gait speed, gait endurance, functional mobility	–

Biofeedback

Adopted from: http://aim2walk.ca/stabilometric-platform/ ; https://mikereinold.com/why-you-should-be-using-biofeedback-in-rehabilitation/

Table 15. Classification of Biofeedback used for stroke rehabilitation (Giggins et al., 2013) Biofeedback category Subcategories Examples Biomechanical Movement • Inertial sensors Postural Control • Force plates Force • Electrogoimeters • Pressure biofeedback units • Camera based systems • Physiotherapist comments Physiological Neuromuscular system • EMG biofeedback • Real time ultrasound imagining biofeedback Cardiovascular system • Heart rate biofeedback • Heart rate variability biofeedback Respiratory system • Breathing electrodes and sensors that convert breathing to auditory and visual signals Biofeedback is a longstanding technique used within rehabilitation that involves providing real- time biological information to patients as a form of augmented or extrinsic feedback during rehabilitation (Giggins et al. 2013). Feedback provided is extrinsic as opposed to intrinsic because additional information is provided beyond self-generated information from intrinsic sensory receptors (Giggins et al. 2013). Providing additional and detailed feedback to patients during rehabilitation may produce a positive impact on their learning and performance through improving accuracy during functional tasks and increasing engagement during rehabilitation (Giggins et al., 2013; Johnson et al., 2013).

There are two strategies through which biofeedback is relayed to the user. The first option is through direct feedback, in which a physiological measurement such as heart rate is displayed (Giggins et al. 2013). The second way is through transformed feedback, in which measurements are used to inform and produce an auditory, visual, or tactile feedback signal (Giggins et al. 2013). Biofeedback can be classified most broadly into biomechanical or physiological categories (Table 15). Biomechanical feedback can be further broken down based on measurements of movement, postural control, and force (Giggins et al. 2013). Physiological feedback can be broken down based on measurements of the neuromuscular, cardiovascular, and respiratory systems (Giggins et al. 2013).

Electromyography (EMG) biofeedback therapy uses surface electrodes to detect changes in skeletal muscle activity, which is then transformed to a visual or auditory feedback signal (Giggins et al 2013). It is used to increase activity within a paretic muscle or can be used to reduce tone in a spastic muscle (Giggins et al. 2013).

A total of 67 RCTs were found that evaluated biofeedback for lower extremity motor rehabilitation. Four RCTs compared Gait Training with Visual Feedback with Gait Training or Conventional Therapy (Evron et al. 2024; Kim et al. 2020b; Pignolo et al. 2020; Byl et al. 2015). Six RCTs compared Treadmill Training with Visual Biofeedback with Treadmill Training (Shin et al. 2022; Druzbicki et al. 2018; Druzbicki et al. 2016a; Druzbicki et al. 2016b; Brasileiro et al. 2015; Druzbicki et al. 2015). Five RCTs compared Gait Training with Activity Feedback with Gait Training or Conventional Therapy (Waddell et al. 2022; Phonthee et al. 2020; Danks et al. 2016; Dorsch et al. 2015; Mansfield et al. 2015). Three RCTs compared Gait Training with Postural Control Visual Feedback with Gait Training or EMG Biofeedback (Khallaf et al. 2014; Balci et al. 2013; Mandel et al. 1990). Five RCTs compared Trunk Training with Visual Biofeedback with Conventional Therapy (Shin et al. 2020; Jung et al. 2017a; Shin & Song 2016; Chung et al. 2014; Chae et al. 2011). Nine RCTs compared Rehabilitation with EMG biofeedback with Conventional Therapy (Dost Surucu & Tezen 2021; Gamez et al. 2019; Tsaih et al., 2018; Xu et al. 2015; Jonsdottir et al. 2010; Bradley et al. 1998; Intiso et al. 1994; Cozean et al. 1988; Mulder et al. 1986). One RCT compared Lokomat Training with Galvanic Vestibular Stimulation or Physiotherapy with Visual Feedback (Krewer et al. 2013). One RCT compared Balance Training with Computer-based Visual Feedback with Mirror Feedback (Yang et al. 2015). One RCT compared Cycling Training with Biofeedback with Conventional Rehabilitation (Yang et al. 2014). Seven RCTs compared Overground Gait Training with Auditory Feedback with Gait Training (Jung et al. 2020a; Choi et al. 2019; Cha et al. 2018; Jung et al. 2015; Sungkarat et al. 2011; Dobkin et al. 2010; Aruin et al. 2003). One RCT compared Verbal Feedback During Walking with Tactile Feedback During Walking (Ploughman et al. 2018). Two RCTs

evaluated Biofeedback combined with sit-to-stand training (Hyun et al. 2021; Cheng et al. 2001). Seven RCTs compared Balance Training with Biofeedback with Balance Training or Conventional Therapy (Lu et al. 2024; Yeo et al. 2023; Elshinnawy et al. 2022; Liao et al. 2018; Lupo et al. 2018; Hung et al. 2016b; Maciaszek et al. 2014). Two RCTs compared Target or Reach Visual Feedback Training with Conventional Rehabilitation (Pak et al. 2020; Khumsapsiri et al. 2018). One RCT compared Strength Training with Visual Feedback with Physical Therapy (Cho et al. 2021). Two RCTs compared Perceptual Feedback with Conventional Treatment (Rao et al. 2023; Morioka et al. 2003). Two RCTs compared Robot-Assisted Gait Training with Biofeedback with No Biofeedback or Conventional Biofeedback (Maggio et al. 2021; Tamburella et al. 2019). One RCT compared Visual Biofeedback with Orthotic Devices with Sham Feedback (Tamburella et al. 2017). One RCT compared Neurofeedback with Sham (Lee et al. 2015g). One RCT compared Knowledge of Results with Knowledge of Performance Feedback Training (Kwon et al. 2024). One RCT compared EMG Biofeedback During Single Support Phase with Stance Phase (Skvortsov et al. 2024).

In addition, 38 RCTs in which biofeedback formed part of a combined or comparative intervention are cross-referenced at the end of Table 15; their primary listings appear in other tables.

The methodological details and results of all 67 RCTs are presented in Table 15.

Table 15. RCTs Evaluating Biofeedback for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Gait Training with Visual Feedback vs Gait Training or Conventional Therapy		
Evron et al. (2024) RCT (3) Nstart=33 Nend=25 TPS=Acute A vs 0	E: "Selfit" gait exercises with visual feedback + conventional rehabilitation C: conventional rehab Duration: 30min/d, 6 sessions	E vs C: TUG(+exp) DGI(-) 10MWT(-) ABC(-)
Kim et al. (2020b) RCT (5) Nstart=30 Nend=24 TPS=Chronic A vs B Also in Table 7 (Non-Technological Overground Walking and Gait Training)	E: Visual performance feedback training during overground walking + conventional physical therapy C: Overground walking without feedback + conventional physical therapy Duration: 30min/d overground walking & 60min/d physical therapy, 3d/wk, 6wk	E vs C: Timed Up and Go test (+exp) Step length (+exp) Stride length (+exp) Single support time on affected side (+exp) Double support time (-) Walking velocity (+exp) Step length ratio (-) Stride length ratio (+exp) Single support time ratio (+exp)
Pignolo et al. (2020) RCT (7) Nstart=66 Nend=63 TPS=Subacute A1 vs A2 vs B	E1: Gait training sessions using the computerized body-weight- support system with real-time interactive visual feedback E2: Gait training sessions using the computerized body-weight- support system without visual feedback C: Neuromotor conventional treatment Duration: 2hr, 5d/wk, 6wks conventional therapy in control group & 60min gait training + 60min conventional therapy, 5d/wk, 6wks for intervention groups	E1 vs E2/C: Tinetti balance scales (+exp1) Functional Independence Measures (+exp1) Trunk Control Test (-) Motricity Index (-) Fugl-Meyer Lower Extremities scale test (-) Static gait balance (+exp1)
Byl et al. (2015) RCT (4)	E: Gait training enhanced with visual kinematic biofeedback	E vs C: 10-Metre Walk Test (-)

Nstart=24 Nend=23 TPS=Chronic A vs 0	C: Gait training Duration: 90min, 12sessions over 6-8wk	Step length (-) 6-Minute walk test (-) Dynamic Gait Index (-) Tinetti Gait Scale (-) Timed Up and Go Test (-) Five times Sit-to-Stand test (-) Berg Balance Scale (-) Strength LE (-) Range of motion (-)
Treadmill Training with Visual Biofeedback vs Treadmill Training		
Shin et al. (2022) RCT (8) Nstart=32 Nend=32 TPS=Chronic A + B vs C	E: Visual feedback + rhytmic auditory cues + conventional rehab C: Treadmill training + conventional rehab Duration: 3d/wk, 8wks	E vs C: Gait speed(+exp) Cadence(+exp) step length(+exp) BBS(+exp) TUG(+exp) Spatial/temporal asymmetry(+exp) paretic single limb support (+exp) non paretic single limb support (-)
Druzbicki et al. (2018) RCT (7) Nstart=30 Nend=30 TPS=Acute A + B vs A Also in Table 9 (Treadmill Training)	E: Body weight support treadmill training + visual biofeedback C: Body weight support treadmill training Duration: 30min/d, 5d/wk for 3wks	E vs C: Stance phase Paretic (-) Non paretic (-) Symmetry Index Stance Phase (-) Swing Phase (-) Step Length (+exp) Swing phase Paretic (-) Non paretic (-) Cadence (-) Gait speed (-) Step length Paretic (-) Non paretic (-) 10-metre walk test (+exp) 2-minute walk test (+exp) Timed Up and Go (-)
Druzbicki et al. (2016a) RCT (8) Nstart=30 Nend=30 TPS=Chronic A + B vs A Also in Table 9 (Treadmill Training)	E: Treadmill training + visual biofeedback + physiotherapy exercises C: Treadmill training + physiotherapy exercises Duration: 90min/d, 5d/wk for 2wk	E vs C: Step length Paretic side (-) Non paretic side (-) Stance phase Paretic side (-) Non paretic side (-) Swing phase Paretic side (-) Non paretic side (-) Range of motion Hip Paretic side (-) Non paretic side (-) Range of motion Knee Paretic side (-)

		Non paretic side (-)
Druzbicki et al. (2016b) RCT (7) Nstart=46 Nend=46 TPS=Chronic A vs B Also in Table 9 (Treadmill Training)	E: Treadmill training with Gait Trainer 2 Biodex biofeedback (30-45min/d) + Conventional individual exercises C: Treadmill training without biofeedback + Conventional individual exercises Duration: 70min/d (30-45min/d treadmill training + individual exercises), 5d/wk, 12d	E vs C: Static balance (-) Timed Up and Go (-) Center of Pressure Length Eyes Open (-) Eyes Closed (-) Sway Area Eyes Open (-) Eyes Closed (-) Center of Pressure in Mediolateral Range Scalar with Eyes Open (-) Eyes Closed (-) Center of Pressure in Anterioposterior Range Scalar with Eyes Open (-) Eyes Closed (-) Symmetry ratio of lowerlimb load ()
Brasileiro et al. (2015) RCT (6) Nstart=30 Nend=30 TPS=Chronic A + B vs A + C vs A Also in Table 9 (Treadmill Training)	E1: Partial body-weight support treadmill training + Visual biofeedback E2: Partial body-weight support treadmill training + Auditory biofeedback C: Partial body-weight support treadmill training Duration: 20min/1session	E vs C: Speed Stride Length (-) Cadence (-) Stance Time (-) Symmetry Ratio (-) Max hip extension during stance (-) Max hip flexion during swing (-) Hip range of motion (-) Knee angle at initial contact (-) Max knee flexion during swing (-) Knee range of motion (-) Ankle angle at initial contact (-) ankle angle at toe-off (-) ankle range of motion (-)
Druzbicki et al. (2015) RCT (7) Nstart=50 Nend=50 TPS=Chronic A + B vs A Also in Table 9 (Treadmill Training)	E: Treadmill training + visual biofeedback + basic physiotherapy C: Treadmill training + basic physiotherapy Duration: 150min/d, 5d/wk, 2wks	E vs C: 10-Metre Walk Test (-) 2-Minute Walk Test (-) Timed Up & Go Test (-) Cadence (-) Gait velocity (-) Swing phase Paretic (-) Non paretic (+exp) Stance phase Paretic (-) Non paretic (+exp) Length of gait cycle Paretic (-) Non paretic (+exp) Barthel Index (-)
Gait Training with Activity Feedback vs Gait Training or Conventional Therapy		
Waddell et al. (2022) RCT (4)	E: Wearable wrist device to engage in game (feedback through points and	E vs C: Daily Steps (+exp)

Nstart=34 Nend=34 TPS=Chronic A1 vs A2	levels, weekly emails and daily texts) to meet step goal C: Wearable wrist device with basic feedback to meet step goal Duration: 8wks	Proportion of days acheiving step goal (+exp)
Phonthee et al. (2020) RCT (7) Nstart=39 Nend=36 TPS=Chronic A vs B	E: Stepping Training with External Feedback C: Stepping Training Alone Duration: 40min, 5d/wk, 4wks	E vs C: Lower limb support period (+exp) Single limb support period (affected) (+exp) Timed Up and Go Test (+exp) 10-Meter Walk Test (-) 6-Minute Walk Test (-) Step length (affected/non-affected) (-) Step length symmetry (-)
Danks et al. (2016) RCT (4) Nstart=37 Nend=27 TPS=Chronic A + B vs A	E: Fast Walking training (FAST) + Step activity monitoring (SAM) program C: Fast Walking training (FAST) Duration: 30min/d, 3d/wk, 12wks	E vs C: Steps per Day (-) Total Time Walking Per Day (-) 10-Meter Walk Test Self-selected speed (-) Maximal speed (-) 6-Minute-Walk Test: Distance (+exp)
Dorsch et al. (2015) RCT (6) Nstart=151 Nend=125 TPS=Acute A1 vs A2	E1: Gait training with Augmented Accelerometer feedback (speed and activity) C: Gait training with Accelerometer feedback on speed only Duration: variable duration, received feedback 3d/wk	E1 vs C: 15m Walking speed (-) 3-minute walking distance (-) Functional Ambulatory category (-) Stroke Impact Scale-16 (-)
Mansfield et al. (2015) RCT (8) Nstart=60 Nend=57 TPS=Acute A vs B	E: Accelerometer-based feedback + Walking training C: Walking training without feedback Duration: 60min/d, 5d/wk	E vs C: Total walking duration (-) Total number of steps (-) Cadence (+exp) Longest bout duration (-) Number of long walking bouts (-) Gait data Walking speed (+exp) Step length symmetry (-) Swing time symmetry (-) Step length variability (-) Step time variability (+exp) Step width variability (-) Stroke self-efficacy (-)
Gait Training with Postural Control Visual Feedback vs Gait Training or EMG Biofeedback		
Khallaf et al. (2014) RCT (5) Nstart=16 Nend=16 TPS=Chronic A + B vs 0 Also in Table 5 (Task-Specific Training)	E: Gait training with postural control visual feedback on monitor + task specific exercises C: Gait training + physiotherapy Duration: 90min/d, 5d/wk, 8wks Exercises Treatment Group & 50min/d, 5d/wk, 8wks Exercises Control Group	E vs C: Foot placement/contact during walking (+exp)
Balci et al. (2013) RCT (6) Nstart=25	E1: Vestibular rehabilitation (consisted of eye-head coordination exercises, balance and ambulation exercises)	E2 vs E1 vs C: Berg Balance scale (-) Timed Up and Go test (No stats) Dizziness Handicap inventory (-)

Nend=25 TPS=Acute A vs B vs C	E2: Visual feedback: Posturography Training C: Usual Home Exercise Duration: 10min, 2-3sessions/d (20-30min/d), 6wks vestibular rehabilitation & 25-30min, 3d/wk, 6wks visual feedback training & 20-30min/d, 6wks usual home exercise	Dynamic gait index (-) Center of Gravity Sway Velocity (-) Limit of Stability (-)
Mandel et al. (1990) RCT (3) Nstart=37 Nend=37 TPS=Chronic A1 vs A2 vs 0	E1: Electromyographic with novel biofeedback E2: Electromyographic with novel biofeedback for 6wks, then rhythmic positional novel biofeedback for last 6wks C: No treatment Duration: 12wks	E2 vs C: Gait speed (+exp2) E1 vs E2/C: Passive plantar flexor torque (-) Borg RPE (-)
Trunk Training with Visual Biofeedback vs Conventional Therapy		
Shin et al. (2020) RCT (7) Nstart=24 Nend=24 TPS=Chronic A vs 0 Also in Table 4 (Trunk Training)	E: Smartphone-based visual feedback trunk control training + Conventional rehabilitation C: Conventional Rehabilitation Duration: 50min/d, 5d/wk, 4wk Conventional Rehabilitation	E vs C: Trunk Impairment Scale (+exp) Velocity (+exp) Cadence (+exp) Stride length (+exp) Stride Time (+exp) Step length (+exp) Step width (+exp) Step time (+exp) Double Limb support (+exp)
Jung et al. (2017a) RCT (6) Nstart=46 Nend=43 TPS=Chronic A + B vs A Also in Table 4 (Trunk Training)	E: Trunk stabilization exercises + audiovisual biofeedback (Pressure biofeedback unit) C: Trunk stabilization exercises Duration: 50min/d, 5d/wk,6wks	E vs C: Thickness of trunk muscles (+exp) TrA-affected (+exp) TrA-unaffected (+exp) IO-affected (-) IO-unaffected (-) EO-affected (+con) EO-unaffected (+con) Symmetric ratio (-) static sitting balance ability (+exp) dynamic sitting balance ability (+exp)
Shin & Song (2016) RCT (6) Nstart=24 Nend=24 TPS=Chronic A vs 0 Also in Table 4 (Trunk Training)	E: Smartphone visual feedback for trunk control training + Conventional care C: Conventional care Duration: 80min/d conventional care + 20min/d Smartphone therapy, 5d/wk, 4wks	E vs C: Timed Up and Go (+exp) Static balance Eyes closed (+exp) Eyes open (+exp) Trunk Impairment scale (+exp) Modified Functional reach test (+exp)
Chung et al. (2014) RCT (4) Nstart=26 Nend=19 TPS=Chronic A + B vs A Also in Table 4 (Trunk Training)	E: Core stability exercises + real time feedback + conventional physical therapy C: Core stability exercises + conventional physical therapy Duration: 30min/session, 3d/wk for 6wks	E vs C: Timed Up and Go test (+exp) Gait velocity (+exp) Gait cadence (-) Affected side Stride length (+exp) Step length (-) Single support time (+exp) Double support time (-)

		Non-affected side Stride length (+exp) Step length (-) Single support time (-) Double support time (-)
Chae et al. (2011) RCT (5) Nstart=21 Nend=21 TPS=Chronic A + B vs 0	E: Spinal stabilization exercise + postural control visual biofeedback C: Conventional rehabilitation Duration: 30min/d, 5d/wk for 8wks	E vs C: Gait speed (-) Cadence (-) Step length (-) Step length asymmetry ratio (-) Single support time (-) Functional Ambulation Category (-)
Rehabilitation with EMG biofeedback vs Conventional Therapy		
Dost Surucu & Tezen (2021) RCT (4) Nstart=40 Nend=40 TPS=Subacute A vs 0	E: EMG biofeedback + Conventional physical therapy C: Conventional physical therapy Duration: 20min/d, 5d/wk, 3wks EMG biofeedback	E vs C: Modified Ashworth scale (+exp) Active dorsiflexion ankle range of motion (+exp) Brunnstrom recovery stages (+exp) Modified Motor assessment scale Sitting to standing (+con) Walking (+con) EMG activity of Tibialis Anterior (+exp)
Gamez et al. (2019) RCT (6) Nstart=40 Nend=28 TPS=Acute A vs 0	E: Surface electromyography-biofeedback (sEMG-B) + conventional care C: Conventional care Duration: 60min/d, 2d/wk, for 12wks	E vs C: Mean activity of EMG signals Upper limb hemiparetic side (+exp) Upper limb normal side (-) Lower limb hemiparetic side (+exp) Lower limb normal side (+exp) Barthel Index (+exp) Fugl Meyer Assessment Upper limb (-) Lower limb (+exp) Isometric strength of the wrist (-) Daniels and Worthingham's muscle testing (-) Kendall's Manual Muscle Test (-) Lovett's test (-)
Tsaih et al. (2018) RCT (7) Nstart=33 Nend=33 TPS=Chronic A1 vs A2 vs B	E1: Constant-force EMG- biofeedback Tibalis anterior training + general Physiotherapy E2: Variable-force EMG- biofeedback Tibalis anterior training + general Physiotherapy C: Upper extremity exercise + general Physiotherapy Duration: 40min/d, 3d/wk for 6wks	E1/E2 vs C: Muscle strength (+exp1, +exp2) Limit of stability anterior (-) posterior (+exp1) Timed Up and Go (-) 6min Walk test (-) 10m Walk test (-) E1 vs E2: Muscle strength (-) Limit of stability anterior (-) posterior (+exp2) Timed Up and Go (-) 6min Walk test (-) 10m Walk test (-)

Xu et al. (2015) RCT (5) Nstart=40 Nend=40 TPS=Subacute A + B vs 0	E: Comprehensive rehabilitation + EMG biofeedback C: Conventional rehabilitation Duration: 20min/d, 5d/wk EMG & 40min/d, 5d/wk comprehensive rehabilitation	E vs C: Fugl-Meyer Assessment (+exp) Functional Ambulation Category (+exp) Integrated Electromyography of Gastrosnemius (+exp)
Jonsdottir et al. (2010) RCT (7) Nstart=20 Nend=20 TPS=Chronic A vs 0	E: Rehabilitation + EMG biofeedback C: Conventional rehabilitation Duration: 45min/d, 3d/wk, 6wks (20 sessions totally)	E vs C: Gait speed (+exp) Stride length (+exp) Ankle power (+exp) Knee flexion (-)
Bradley et al. (1998) RCT (4) Nstart=23 Nend=19 TPS=Acute A vs 0	E: EMG biofeedback + conventional physical therapy C: Sham biofeedback + conventional physical therapy Duration: If inpatients: 3d/wk EMG + PT and 2d/wk PT only & If discharged: 3d/wk EMG + PT, 18sessions/ 6wks.	E vs C: Modified Bobath Scale (-) Modified Ashworth Scale (-) Sensation and Proprioception (-) 10 metre walk test Time in seconds (-) Number of steps (-) Step Length (-) Stride Width (-) Foot angle (-) Rivermead Mobility Index (-) Nottingham Extended ADL index (-) Mental Status Questionnaire (-) National Adult Reading Test (-) Ravens' Coloured Progressive Matrices (-) Rey Auditory Verbal Learning Test (-) Rey Osterrieth Figure Copying Test (-) Token Test (-)
Intiso et al. (1994) RCT (6) Nstart=16 Nend=14 TPS=Chronic A vs 0	E: EMG biofeedback training + conventional physiotherapy C: Conventional physiotherapy Duration: 60min/d, 7d/wk, 8wks physiotherapy & 30 sessions EMG-biofeedback	E vs C: Barthel Index (No stats) Canadian Neurological scale (No stats) Adams scale (No stats) Basmajian scale (No stats) Ashworth scale (No stats) Integrated surface EMG signal (No stats) Step length (-) Velocity (-) Ankle dorsiflexion in swing phase (+exp)
Cozean et al. (1988) RCT (6) Nstart=36 Nend=32 TPS=Chronic A vs B vs A + B vs 0 Also in Table 28 (Functional Electrical Stimulation)	E1: Rehabilitation + EMG biofeedback E2: Rehabilitation + Functional electrical stimulation E3: Rehabilitation + EMG biofeedback + Functional electrical stimulation C: Conventional rehabilitation Duration: 30min/d, 3d/wk for 6wk	E1/E2/E3 vs C: Knee flexion (+exp3) Ankle dorsiflexion (+exp3) Stride length (-) Cycle time (+exp3)
Mulder et al. (1986) RCT (4) Nstart=12 Nend=12	E: Motor relearning + EMG biofeedback C: Motor relearning Duration: 40min/d, 3d/wk for 5wk	E vs C: EMG activity (-) Gait velocity (-) Range of motion (-)

TPS=Chronic A + B vs A Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)		
Lokomat Training vs Galvanic Vestibular Stimulation or Physiotherapy with Visual Feedback		
Krewer et al. (2013) RCT crossover (5) Nstart=25 Nend=24 TPS=Chronic A vs B vs C Also in Table 27 (Electromechanical and Robotic Devices)	E1: Galvanic vestibular stimulation E2: Lokomat gait training E3: Physiotherapy with visual feedback Duration: 20min session – 1d washout	E1 vs E2/E3: Burke Lateropulsion Scale (-) Scale for Contraversive Pushing (-) E2 vs E3: Burke Lateropulsion Scale (+exp2) Scale for Contraversive Pushing (-)
Balance Training with Computer-based Visual Feedback vs Mirror Feedback		
Yang et al. (2015) RCT (7) Nstart=12 Nend=12 TPS=Subacute A1 vs A2 Also in Table 11 (Balance Training)	E: Computer-generated interactive visual feedback balance training + Physical therapy C: Mirror visual feedback balance training + Physical therapy Duration: 20min/d - Balance training, 20min/d - Physical therapy, 3d/wk, 3wks	E vs C: Pusher syndrome severity (+exp) Berg balance scale (+exp) Fugl-Meyer assessment upper extremity (-) lower extremity (+exp)
Cycling Training with Biofeedback vs Conventional Rehabilitation		
Yang et al. (2014) RCT crossover (7) Nstart=31 Nend=30 TPS=Chronic A + B vs 0 Also in Table 8 (Cycle Ergometer Training)	E: Conventional Rehabilitation + Cycling training + biofeedback C: Conventional Rehabilitation (CR) Duration: 30min/d for 4wks Cycling ; 120min/d for 4wks Conventional rehabilitation – no washout	E vs C: Fugl-Meyer assessment-lower limb (+exp) 6min Walk test (+exp) 10m Walk Test (+exp) Modified Ashworth Scale (+exp)
Overground Gait Training with Auditory Feedback vs Gait Training		
Jung et al. (2020a) RCT (7) Nstart=20 Nend=20 TPS=Chronic A vs 0	E: Gait training (walking overground) + auditory feedback + conventional exercise C: Gait training (walking overground) + conventional exercise Duration: 60 mins, 5d/wk, 4 wks	E vs C: Peak vertical force on cane (+exp) EMG (Muscle activation % peak activity) (+exp) Trunk impairment scale (-): Static (-) Dynamic (-) Coordination (-) Timed Up and Go Test (+exp)
Choi et al. (2019) RCT (6) Nstart=24 Nend=24 TPS=Chronic A vs B	E1: Gait training with auditory feedback caused by active weight bearing on their paralyzed foot E2: General gait training over the ground Duration: 20min gait intervention + 30min conventional rehabilitation, 3x/wk, for 6wks	E1 vs E2: 10m walk test (+exp) Functional gait assessment (+exp) Timed up and go test (+exp) Center of pressure path length (+exp)
Cha et al. (2018) RCT (8) Nstart=31 Nend=31	E1: Gait training by active weight bearing on the paretic heel with auditory feedback + Conventional therapy	E1/E2 vs C: 10-metre walking test (-) Functional gait assessment(+exp2) Timed Up and Go test (-)

TPS=Chronic A1 vs A2 vs 0	E2: Gait training by active weight bearing on the paretic metatarsals with auditory feedback + Conventional therapy C: General gait intervention + Conventional therapy Duration: 30min, 3d/wk, 6wks conventional therapy & 20min, 3d/wk, 6wks gait training	Center of loading- path length: Eyes open (+exp1, +exp2) Eyes closed (-) Center of loading- path velocity: Eyes open (+exp1, +exp2) Eyes closed (-)
Jung et al. (2015) RCT (7) Nstart=22 Nend=21 TPS=Chronic A vs 0	E: Gait training + Auditory feedback from cane + Conventional rehabilitation C: Gait training + Conventional rehabilitation Duration: 30min/d, 5d/wk for 4wks - Gait training, 1h/d, 5d/wk for 4wks - Conventional rehabilitation	E vs C: Walking speed (+exp) Single limb support phase (+exp) Surface EMG Gluetus medius (+exp) Vastus medialis oblique (+exp)
Sungkarat et al. (2011) RCT (7) Nstart=40 Nend=35 TPS=Subacute A + B vs 0 Also in Table 13 (Orthotic Devices)	E: Gait training with Insole Shoe Wedge and Sensors + Auditory feedback + Conventional rehabilitation C: Conventional gait training + Conventional rehabilitation Duration: 30min/d, 5d/wk for 3wks - Conventional rehabilitation, 30min/d, 5d/wk for 3wks - Gait training	E vs C: Gait speed (+exp) Step length asymmetry ratio (+exp) Single support time asymmetry ratio (+exp) Berg balance scale (+exp) Timed up and go (+exp) Loading on paretic leg during stance (+exp)
Dobkin et al. (2010) RCT (7) Nstart=179 Nend=162 TPS=Acute A vs 0	E: Gait training + positive reinforcement about walking speed C: Gait training Duration: 4wk	E vs C: Walking speed (+exp) Length of rehabilitation stay (-) Walking distance (-) Functional Ambulatory category (-)
Aruin et al. (2003) RCT (3) Nstart=16 Nend=16 TPS=Acute A vs 0	E: Gait training + Auditory feedback C: Conventional gait therapy Duration: 25min (2sessions/d), for 10d	E vs C: Step Width (+exp)
Verbal Feedback During Walking vs Tactile Feedback During Walking		
Ploughman et al. (2018) RCT crossover (7) Nstart=10 Nend=10 TPS=Subacute A1 vs A2	E1: Verbal Cues and Feedback During Walking E2: Tactile Cues and Feedback During Walking Duration: Single Session, 7-10 day washout	E1 vs E2: Cadence (+exp) Velocity (+exp) Double support time (+exp) step length symmetry (-) hip kinematics (-) knee kinematics (-) Ankle kinematics (-) EMG muscle activity gluteus maximum (-) gluteus medius (-) vastus lateralis (+con) medial hamstrings (-) tibialis anterior (-) medial gastrocnemius (+con)

Biofeedback combined with sit-to-stand training		
Hyun et al. (2021) RCT (5) Nstart=40 Nend=30 TPS=Subacute A + B vs A Also in Table 2 (Sit-to-Stand Training); Table 26 (Virtual Reality)	E: Sit-to-stand training + visual feedback with Wii Balance Board + Standard physiotherapy C: Sit-to-stand Training + Standard physiotherapy Duration: 20min/d, 5d/wk, 6 wks sit-to-stand training & 30min/d, 5d/wk, 6wks physiotherapy	E vs C: Manual muscle Strength test of the Lower Extremities Hip flexor (+exp) hip abductor (+exp) knee extensor (+exp) Centre of Pressure (+exp) Berg Balance Scale (+exp) 10 meter walking test (+exp) Timed Up and Go test (+exp) Stroke-Specific Quality of Life (+exp)
Cheng et al. (2001) RCT (5) Nstart=54 Nend=54 TPS=Subacute A + B vs 0 Also in Table 2 (Sit-to-Stand Training)	E: Standing postural symmetry training with a visual and auditory biofeedback trainer + repetitive sit-to-stand training+ conventional rehabilitation C: Conventional rehabilitation Duration: 30min/d postural training & 20min/d sit-to-stand training, 5d/wk for 3wks	E vs C: Rate of falls (No stats) the anteroposterior COP (No stats) mediolateral COP (No stats) Rate of rise in force during rising from a chair (No stats) time needed to rise and sit (No stats)
Balance Training with Biofeedback vs Balance Training or Conventional Therapy		
Lu et al. (2024) RCT (8) Nstart=62 Nend=62 TPS=Acute A + B vs C Also in Table 11 (Balance Training)	E: Pro-Kin system + weight loss system (body-weight support) with balance training C: Conventional balance training Duration: C: 20 mins/session, 10 times/wk, 4 wks. (2002) RCT (4) Nstart=41 Nend=41 TPS=Subacute A + B vs 0 Primary listing: Table 11 (Balance Training)	E: Balance training + postural control visual biofeedback (SMART Balance master) C: Conventional rehabilitation Duration: Not Specified	E vs C: Functional Independent Measure selfcare and sphincter control (No stats) mobility and locomotion (No stats) static balance maximal stability (No stats) ankle strategy (No stats) center of gravity alignment (No stats) dynamic balance axis velocity (No stats) directional control (No stats) end point excusion (No stats)
De Seze et al. (2001) RCT (6) Nstart=20 Nend=20 TPS=Subacute A vs B Primary listing: Table 4 (Trunk Training)	E: Trunk postural control training with visual and auditory feedback + Conventional neurorehabilitation C: Conventional neurorehabilitation Duration: 120min/d, 5d/wk for 3mo	E vs C: Motricity Index (-) Ashworth scale (-) Mini-mental status exam (-) Upright Equilibrium Index (+exp) Sitting Equilibrium Index (-) Functional Ambulation Category (+exp) Functional Independence Measure (-) Trunk Control Test (+exp) Bells Neglect Test (+exp)
Geiger et al. (2001) RCT (5) Nstart=13 Nend=13 TPS=Subacute A vs 0 Primary listing: Table 11 (Balance Training)	E: Physical therapy + visual biofeedback (SMART Balance master forceplate) C: Physical therapy Duration: 50min/d, 2-3d/wk for 4wks	E vs C: Berg Balance Scale (-) Timed Up & Go Test (-)
Walker et al. (2000) RCT (4) Nstart=54 Nend=46 TPS=Subacute A + B vs A + C vs 0 Primary listing: Table 11 (Balance Training)	E1: Balance training + Visual feedback E2: Balance training + Verbal and tactile cues C: Conventional rehabilitation Duration: 30min/d, 5d/wk for 3- 8wks Balance training, 120min/d, 5d/wk Conventional rehabilitation	E1 vs E2 vs C: Postural sway Eyes open (-) Eyes closed (-) Berg Balance Scale (-) Timed Up & Go Test (-) 10-m walk test (-)
Sackley & Lincoln (1997) RCT (6) Nstart=26 Nend=24 TPS=Subacute A + B vs B Primary listing: Table 11 (Balance Training)	E: Visual feedback + Nottingham Balance Platform training + physical therapy C: Sham visual feedback + Nottingham Balance Platform training + physical therapy Duration: 60min/d, 3d/wk, for 4wks	E vs C: Balance co-efficient (+exp) Rivermead Motor assessment (+exp) Leg and trunk (-) Gross function (+exp) Nottingham 10-point Activities of Daily Life scale (+exp) Stance symmetry (+exp) Sway (+exp)
Wong et al. (1997) RCT (5) Nstart=60 Nend=60	E: Standing practice + Force platform biofeedback C: Standing training table Duration: 60min/d, 5d/wk, for 3- 4wks	E vs C: Postural symmetry (+exp)

TPS=Acute A + B vs C Primary listing: Table 11 (Balance Training)		
Engardt et al. (1993) RCT (5) Nstart=42 Nend=40 TPS=Subacute A vs B Primary listing: Table 2 (Sit-to-Stand Training)	E: Continuous Auditory Feedback During Sit-to-Stand Training C: No Feedback During Sit-to- stand Training Duration: 15min/session, 3sessions/d, 5d/wk, 6wks	E vs C: Weight distribution (+exp) Motor Assessment Scale (+exp) Barthel Index (-) Fugl-Meyer Assessment (+exp)
Cozean et al. (1988) RCT (6) Nstart=36 Nend=32 TPS=Chronic A vs B vs A + B vs 0 Primary listing: Table 28 (Functional Electrical Stimulation)	E1: Gait training + FES E2: Gait training + Biofeedback E3: Gait training + FES + Biofeedback C: Standard care Duration: 30min/d, 3d/wk for 6wks	E3 vs E1/E2/C: Gait cycle time (+exp3) Stride length (-) Knee flexion (+exp3) Ankle flexion (+exp3)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Gait Training with Visual Feedback may not have a difference in efficacy when compared to Gait Training or Conventional Therapy for improving motor recovery.	1	Pignolo et al. 2020
1a	Rehabilitation with electromyography biofeedback may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	5	Dost Surucu & Tezen 2021; Gamez et al. 2019; Xu et al. 2015; Bradley et al. 1998; Intiso et al. 1994
1b	Balance Training with Computer-based Visual Feedback may produce greater improvements in motor recovery than Mirror Feedback.	1	Yang et al. 2015
1b	Cycling Training with Biofeedback may produce greater improvements in motor recovery than Conventional Rehabilitation.	1	Yang et al. 2014
1b	There is conflicting evidence about the effect of Balance Training with Biofeedback when compared to Balance Training or Conventional Therapy for improving motor recovery.	1	Lupo et al. 2018
1b	Strength Training with Visual Feedback may produce greater improvements in motor recovery than Physical Therapy.	1	Cho et al. 2021
1b	There is conflicting evidence about the effect of Robot-Assisted Gait Training with Biofeedback when compared to No Biofeedback or Conventional Biofeedback for improving motor recovery.	1	Maggio et al. 2021

1b	Knowledge of Results (Real-time visual feedback) may not have a difference in efficacy when compared to Knowledge of Performance (Real-time feedback with instructions on how to adjust/ direct cues) for improving motor recovery.	1	Kwon et al. 2024
2	Dynamic sitting excercises in the mediolateral and anteroposterior directions with computer visual feedback with 500 (ms) delay may not have a difference in efficacy when compared to Dynamic sitting excercises in the mediolateral and anteroposterior directions with computer visual feedback in real time for improving motor recovery.	1	Inoue et al. 2022a
1b	Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may produce greater improvements in motor recovery than Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy.	1	Mihai et al. 2022
1b	Whole-Body Tilting Postural Training (Visual feedback monitor with Trunk sensor, 8- direction body tilt and Spine balance 3D) may produce greater improvements in motor recovery than General Postural Training.	1	An et al. 2021
1b	Neurofeedback facilitation with motor imagery may not have a difference in efficacy when compared to Sham neurofeedback with motor imagery for improving motor recovery.	1	Mihara et al. 2021
2	Balance training with postural control visual biofeedback (SMART Balance master) may not have a difference in efficacy when compared to Conventional physical therapy with balance training for improving motor recovery.	1	Rao et al. 2013
1b	Balance training with postural control visual biofeedback from unaffected side and physiotherapy may not have a difference in efficacy when compared to Stand-up task with physiotherapy for improving motor recovery.	1	Varoqui et al. 2011
1b	Balance Training with a kinaesthetic ability training (KAT) device (postural control visual biofeedback) may not have a difference in efficacy when compared to Conventional rehabilitation for improving motor recovery.	1	Alptekin et al. 2008
2	Balance training with force platform biofeedback and Conventional rehabilitation may not have a difference in efficacy when compared to Conventional rehabilitation for improving motor recovery.	1	Eser et al. 2008
1b	Visual feedback with Nottingham Balance Platform training and physical therapy may produce greater improvements in motor recovery than Sham visual feedback with Nottingham Balance Platform training and physical therapy.	1	Sackley & Lincoln 1997
2	Continuous Auditory Feedback During Sit-to-Stand Training may produce greater improvements in motor recovery than No Feedback During Sit-to- stand Training.	1	Engardt et al. 1993

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Gait Training with Visual Feedback may produce greater improvements in biomechanical gait measures than Gait Training or Conventional Therapy.	2	Kim et al. 2020b; Byl et al. 2015
1a	Treadmill Training with Visual Biofeedback may not have a difference in efficacy when compared to Treadmill Training for improving biomechanical gait measures.	5	Shin et al. 2022; Druzbicki et al. 2018; Druzbicki et al. 2016a; Brasileiro et al. 2015; Druzbicki et al. 2015

1a	Gait Training with Activity Feedback may not have a difference in efficacy when compared to Gait Training or Conventional Therapy for improving biomechanical gait measures.	2	Phonthee et al. 2020; Mansfield et al. 2015
2	Gait Training with Postural Control Visual Feedback may produce greater improvements in biomechanical gait measures than Gait Training or electromyography Biofeedback.	1	Khallaf et al. 2014
1a	Trunk Training with Visual Biofeedback may not have a difference in efficacy when compared to Conventional Therapy for improving biomechanical gait measures.	4	Shin et al. 2020; Jung et al. 2017a; Chung et al. 2014; Chae et al. 2011
1a	Rehabilitation with electromyography biofeedback may not have a difference in efficacy when compared to Conventional Therapy for improving biomechanical gait measures.	4	Jonsdottir et al. 2010; Bradley et al. 1998; Intiso et al. 1994; Cozean et al. 1988
1b	Overground Gait Training with Auditory Feedback may produce greater improvements in biomechanical gait measures than Gait Training.	2	Sungkarat et al. 2011; Aruin et al. 2003
1b	Verbal Cues and Feedback During Walking may not have a difference in efficacy when compared to Tactile Cues and Feedback During Walking for improving biomechanical gait measures.	1	Ploughman et al. 2018
1b	Balance Training with Biofeedback may not have a difference in efficacy when compared to Balance Training or Conventional Therapy for improving biomechanical gait measures.	1	Yeo et al. 2023
1b	Visual feedback with Unstable surface balance training may not have a difference in efficacy when compared to Unstable surface balance training for improving biomechanical gait measures.	1	Yeo et al. 2023
2	Robot-Assisted Gait Training with Biofeedback may not have a difference in efficacy when compared to No Biofeedback or Conventional Biofeedback for improving biomechanical gait measures.	1	Tamburella et al. 2019
1b	Neurofeedback may produce greater improvements in biomechanical gait measures than Sham.	1	Lee et al. 2015g
1b	Weight support feedback cane (WSFC) gait training + conventional care may produce greater improvements in biomechanical gait measures than Regular cane gait training + conventional care.	1	Kang et al. 2021a
2	100% performance feedback and scatter plot visual feedback may not have a difference in efficacy when compared to No performance feedback for improving biomechanical gait measures.	1	Powers et al. 2021
1b	Multimodal training: Biofeedback FES +cycling training + biofeedback platform-based balance training + conventional rehabilitation may not have a difference in efficacy when compared to Conventional rehabilitation for improving biomechanical gait measures.	1	Ambrosini et al. 2020
2	EMG biofeedback from the affected-side soleus muscle (EMG) may not have a difference in efficacy when compared to Physical therapy (PT) for improving biomechanical gait measures.	1	Colborne et al. 1993
1b	3D balance training using visual feedback with Conventional therapy may produce greater improvements in biomechanical gait measures than Conventional therapy.	1	Noh et al. 2019
1b	Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit) may not have a difference in efficacy when compared to Trunk stabilization exercises for improving biomechanical gait measures.	1	Jung et al. 2017a
1b	Gaming Assisted Visual feedback for balance training with Conventional therapy may produce greater improvements in	1	James et al. 2017

	biomechanical gait measures than Balance training exercises with Conventional therapy.		
1b	Treadmill training with Rhythmic auditory feedback may produce greater improvements in biomechanical gait measures than Treadmill training.	1	Yang et al. 2016
2	Botulinum Toxin A injection (under ultrasound guidance) with electromyography biofeedback treatment and conventional care may not have a difference in efficacy when compared to Botulinum Toxin A injection (under ultrasound guidance) with conventional care for improving biomechanical gait measures.	1	Chen et al. 2015b
1b	Force platform biofeedback balance training with Conventional rehabilitation may not have a difference in efficacy when compared to Conventional rehabilitation for improving biomechanical gait measures.	1	Yavuzer et al. 2006a
1b	Visual feedback with Nottingham Balance Platform training and physical therapy may produce greater improvements in biomechanical gait measures than Sham visual feedback with Nottingham Balance Platform training and physical therapy.	1	Sackley & Lincoln 1997
2	Standing practice with Force platform biofeedback may produce greater improvements in biomechanical gait measures than Standing training table.	1	Wong et al. 1997
1b	There is conflicting evidence about the effect of Gait training with functional electrical stimulation when compared to care for improving biomechanical gait measures.	1	Cozean et al. 1988

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Treadmill Training with Visual Biofeedback may not have a difference in efficacy when compared to Treadmill Training for improving biomechanical balance measures.	1	Druzbicki et al. 2016b
1b	Gait Training with Postural Control Visual Feedback may not have a difference in efficacy when compared to Gait Training or electromyography Biofeedback for improving biomechanical balance measures.	1	Balci et al. 2013
1b	There is conflicting evidence about the effect of Rehabilitation with electromyography biofeedback when compared to Conventional Therapy for improving biomechanical balance measures.	1	Tsaih et al. 2018
1b	There is conflicting evidence about the effect of Constant-force electromyography- biofeedback Tibalis anterior training with general Physiotherapy when compared to Variable-force electromyography-biofeedback Tibalis anterior training with general Physiotherapy for improving biomechanical balance measures.	1	Tsaih et al. 2018
1b	Gait training with auditory feedback caused by active weight bearing on their paralyzed foot may produce greater improvements in biomechanical balance measures than General gait training over the ground.	1	Choi et al. 2019
2	Standing postural symmetry training with a visual and auditory biofeedback trainer with repetitive sit-to-stand training and conventional rehabilitation may not have a difference in efficacy when compared to Conventional rehabilitation for improving biomechanical balance measures.	1	Cheng et al. 2001
1b	Balance Training with Biofeedback may produce greater improvements in biomechanical balance measures than Balance Training or Conventional Therapy.	2	Lupo et al. 2018; Hung et al. 2016b

1b	Target or Reach Visual Feedback Training may produce greater improvements in biomechanical balance measures than Conventional Rehabilitation.	2	Pak et al. 2020; Khumsapsiri et al. 2018
1b	Perceptual Feedback may not have a difference in efficacy when compared to Conventional Treatment for improving biomechanical balance measures.	1	Morioka et al. 2003
1b	There is conflicting evidence about the effect of Knowledge of Results (Real-time visual feedback) when compared to Knowledge of Performance (Real-time feedback with instructions on how to adjust/ direct cues) for improving biomechanical balance measures.	1	Kwon et al. 2024
2	Visual Deprivation Group Balance Training Group with Conventional Therapy may produce greater improvements in biomechanical balance measures than Conventional Therapy.	1	Jeong et al. 2024
2	Visual Deprivation Group Balance Training Group with Conventional Therapy may produce greater improvements in biomechanical balance measures than Visual Feedback Balance Training Group with Conventional Therapy.	1	Jeong et al. 2024
1b	Pressure sensor-based vibrotactile biofeedback may produce greater improvements in biomechanical balance measures than Standing without biofeedback.	1	Kim et al. 2022e
1b	Visual biofeedback providing posture information may produce greater improvements in biomechanical balance measures than Standing without biofeedback.	1	Kim et al. 2022e
1b	Pressure sensor-based vibrotactile biofeedback may produce greater improvements in biomechanical balance measures than Visual biofeedback providing posture information.	1	Kim et al. 2022e
1b	Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may produce greater improvements in biomechanical balance measures than Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy.	1	Mihai et al. 2022
1b	There is conflicting evidence about the effect of Gaming Assisted Visual feedback for balance training with Conventional therapy when compared to Balance training exercises with Conventional therapy for improving biomechanical balance measures.	1	James et al. 2017
2	Balance training using Biodex stability system with visual biofeedback may not have a difference in efficacy when compared to Balance training for improving biomechanical balance measures.	1	Ghomashchi 2016
1b	Balance Platform Training with Audio-visual Feedback with Rehabilitation program may not have a difference in efficacy when compared to Rehabilitation program with postural training with physiotherapy for improving biomechanical balance measures.	1	De Nunzio et al. 2014
2	Balance training with self- controlled postural control visual biofeedback may produce greater improvements in biomechanical balance measures than Balance training with no control over postural control visual biofeedback.	1	Yoon et al. 2013
2	There is conflicting evidence about the effect of Usual rehabilitation with Sit-to- Stand training and visual feedback when compared to Usual rehabilitation with Arm task training for improving biomechanical balance measures.	1	Britton et al. 2008
1b	Balance Training with a kinaesthetic ability training (KAT) device (postural control visual biofeedback) may produce greater improvements in biomechanical balance measures than Conventional rehabilitation.	1	Alptekin et al. 2008

2	Balance training with postural control visual biofeedback (SMART Balance master) may not have a difference in efficacy when compared to Conventional rehabilitation for improving biomechanical balance measures.	1	Chen et al. 2002
2	Balance training with Visual feedback may not have a difference in efficacy when compared to Balance training with Verbal and tactile cues for improving biomechanical balance measures.	1	Walker et al. 2000
1b	Visual feedback with Nottingham Balance Platform training and physical therapy may produce greater improvements in biomechanical balance measures than Sham visual feedback with Nottingham Balance Platform training and physical therapy.	1	Sackley & Lincoln 1997
2	Continuous Auditory Feedback During Sit-to-Stand Training may produce greater improvements in biomechanical balance measures than No Feedback During Sit-to- stand Training.	1	Engardt et al. 1993
1b	Visual biofeedback training with Conventional rehabilitation may produce greater improvements in biomechanical balance measures than Conventional rehabilitation.	1	Elshinnawy et al. 2022

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Gait Training with Visual Feedback may not have a difference in efficacy when compared to Gait Training or Conventional Therapy for improving muscle strength.	2	Pignolo et al. 2020; Byl et al. 2015
2	Gait Training with Postural Control Visual Feedback may not have a difference in efficacy when compared to Gait Training or electromyography Biofeedback for improving muscle strength.	1	Mandel et al. 1990
1b	There is conflicting evidence about the effect of Trunk Training with Visual Biofeedback when compared to Conventional Therapy for improving muscle strength.	1	Jung et al. 2017a
1b	Rehabilitation with electromyography biofeedback may not have a difference in efficacy when compared to Conventional Therapy for improving muscle strength.	1	Gamez et al. 2019
1b	Constant-force electromyography- biofeedback Tibalis anterior training with general Physiotherapy may not have a difference in efficacy when compared to Variable-force electromyography-biofeedback Tibalis anterior training with general Physiotherapy for improving muscle strength.	1	Tsaih et al. 2018
1b	Constant-force EMG- biofeedback Tibalis anterior training with general Physiotherapy or Variable-force EMG- biofeedback Tibalis anterior training with general Physiotherapy may produce greater improvements in muscle strength than Upper extremity exercise with general Physiotherapy.	1	Tsaih et al. 2018
2	Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy may produce greater improvements in muscle strength than Sit-to-stand Training with physiotherapy.	1	Hyun et al. 2021
2	There is conflicting evidence about the effect of Balance Training with Biofeedback when compared to Balance Training or Conventional Therapy for improving muscle strength.	1	Hung et al. 2016b
1b	Strength Training with Visual Feedback may produce greater improvements in muscle strength than Physical Therapy.	1	Cho et al. 2021
1b	Multimodal training: Biofeedback FES +cycling training + biofeedback platform-based balance training + conventional rehabilitation may not have a difference in efficacy when compared to Conventional rehabilitation for improving muscle strength.	1	Ambrosini et al. 2020

1b	There is conflicting evidence about the effect of Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit) when compared to Trunk stabilization exercises for improving muscle strength.	1	Jung et al. 2017a
2	There is conflicting evidence about the effect of Stepper Exercise with Visual Feedback (with mirror) when compared to Stepper Exercise for improving muscle strength.	1	Choi et al. 2015c
1b	Trunk postural control training with visual and auditory feedback with Conventional neurorehabilitation may not have a difference in efficacy when compared to Conventional neurorehabilitation for improving muscle strength.	1	De Seze et al. 2001

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Rehabilitation with electromyography biofeedback may not have a difference in efficacy when compared to Conventional Therapy for improving spasticity.	3	Dost Surucu & Tezen 2021; Bradley et al. 1998; Intiso et al. 1994
1b	Cycling Training with Biofeedback may produce greater improvements in spasticity than Conventional Rehabilitation.	1	Yang et al. 2014
2	Robot-Assisted Gait Training with Biofeedback may not have a difference in efficacy when compared to No Biofeedback or Conventional Biofeedback for improving spasticity.	1	Tamburella et al. 2019
1b	Visual Biofeedback with Orthotic Devices may produce greater improvements in spasticity than Sham Feedback.	1	Tamburella et al. 2017
1b	Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may produce greater improvements in spasticity than Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy.	1	Mihai et al. 2022
2	Botulinum Toxin A injection (under ultrasound guidance) with electromyography biofeedback treatment and conventional care may not have a difference in efficacy when compared to Botulinum Toxin A injection (under ultrasound guidance) with conventional care for improving spasticity.	1	Chen et al. 2015b
1b	Balance training with postural control visual biofeedback from unaffected side and physiotherapy may not have a difference in efficacy when compared to Stand-up task with physiotherapy for improving spasticity.	1	Varoqui et al. 2011

1b	Weight support feedback cane (WSFC) gait training + conventional care may not have a difference in efficacy when compared to Regular cane gait training + conventional care for improving upper extremity function.	1	Kang et al. 2021a
1b	Neurofeedback facilitation with motor imagery may not have a difference in efficacy when compared to Sham neurofeedback with motor imagery for improving upper extremity function.	1	Mihara et al. 2021

Key Points

- Gait Training with Visual Feedback may be beneficial for improving biomechanical gait measures and activities of daily living, but not motor recovery, muscle strength, range of motion, gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, after stroke when compared to Gait Training or Conventional Therapy.
- Treadmill Training with Visual Biofeedback may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, range of motion, activities of daily living, gait speed, and

functional mobility after stroke when compared to Treadmill Training; the literature is mixed regarding gait endurance and balance.

- Gait Training with Activity Feedback may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and quality of life after stroke when compared to Gait Training or Conventional Therapy; the literature is mixed regarding functional mobility.
- Gait Training with Postural Control Visual Feedback may be beneficial for improving biomechanical gait measures, but not biomechanical balance measures, muscle strength, aerobic measures, functional mobility, balance, and quality of life, after stroke when compared to Gait Training or electromyography Biofeedback; the literature is mixed regarding gait speed.
- Trunk Training with Visual Biofeedback may be beneficial for improving gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Conventional Therapy; the literature is mixed regarding muscle strength.
- Rehabilitation with electromyography biofeedback may be beneficial for improving neurophysiological measures, but not motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, sensory and proprioceptive function, activities of daily living, gait speed, and gait endurance, after stroke when compared to Conventional Therapy; the literature is mixed regarding biomechanical balance measures and functional mobility.
- Constant-force electromyography- biofeedback Tibalis anterior training with general Physiotherapy may not be beneficial for improving muscle strength, gait speed, gait endurance, and functional mobility after stroke when compared to Variable-force electromyography- biofeedback Tibalis anterior training with general Physiotherapy; the literature is mixed regarding biomechanical balance measures.
- Galvanic vestibular stimulation may not be beneficial for improving balance after stroke when compared to Lokomat gait training or Physiotherapy with visual feedback.
- The literature is mixed regarding the effect of Lokomat gait training on balance after stroke when compared to Physiotherapy with visual feedback.
- Balance Training with Computer-based Visual Feedback may be beneficial for improving motor recovery and balance after stroke when compared to Mirror Feedback.
- Cycling Training with Biofeedback may be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Conventional Rehabilitation.
- Overground Gait Training with Auditory Feedback may be beneficial for improving biomechanical gait measures, neurophysiological measures, and gait speed, but not gait endurance, functional mobility, and balance, after stroke when compared to Gait Training.
- Gait training with auditory feedback caused by active weight bearing on their paralyzed foot may be beneficial for improving biomechanical balance measures, gait speed, and functional mobility after stroke when compared to General gait training over the ground.
- Verbal Cues and Feedback During Walking may be beneficial for improving gait speed, but not biomechanical gait measures and neurophysiological measures, after stroke when compared to Tactile Cues and Feedback During Walking.
- Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy may be beneficial for improving muscle strength, gait speed, functional mobility, balance, and quality of life after stroke when compared to Sit-to-stand Training with physiotherapy.
- Standing postural symmetry training with a visual and auditory biofeedback trainer with repetitive sit-to-stand training and conventional rehabilitation may not be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Conventional rehabilitation.
- Balance Training with Biofeedback may be beneficial for improving biomechanical balance measures, range of motion, sensory and proprioceptive function, gait speed, functional mobility, and balance, but not biomechanical gait measures and activities of daily living, after stroke when compared to Balance Training or Conventional Therapy; the literature is mixed regarding motor recovery and muscle strength.
- Visual feedback with Unstable surface balance training may be beneficial for improving functional mobility and balance, but not biomechanical gait measures and gait speed, after stroke when compared to Unstable surface balance training; the literature is mixed regarding range of motion.
- Rehabilitation with Balance training and Visual biofeedback may not be beneficial for improving functional mobility and balance after stroke when compared to rehabilitation program with lateral wedge insole.

- Target or Reach Visual Feedback Training may be beneficial for improving biomechanical balance measures and neurophysiological measures, but not gait speed and balance, after stroke when compared to Conventional Rehabilitation.
- Strength Training with Visual Feedback may be beneficial for improving motor recovery and muscle strength, but not gait speed and balance, after stroke when compared to Physical Therapy; the literature is mixed regarding sensory and proprioceptive function.
- Perceptual Feedback may be beneficial for improving balance, but not biomechanical balance measures, after stroke when compared to Conventional Treatment.
- Robot-Assisted Gait Training with Biofeedback may be beneficial for improving neurophysiological measures, but not biomechanical gait measures, spasticity, pain, activities of daily living, functional mobility, balance, and quality of life, after stroke when compared to No Biofeedback or Conventional Biofeedback; the literature is mixed regarding motor recovery.
- Visual Biofeedback with Orthotic Devices may be beneficial for improving spasticity, but not range of motion, after stroke when compared to Sham Feedback; the literature is mixed regarding gait speed.
- Neurofeedback may be beneficial for improving biomechanical gait measures, sensory and proprioceptive function, gait speed, and functional mobility after stroke when compared to Sham.
- Knowledge of Results (Real-time visual feedback) may not be beneficial for improving motor recovery, gait speed, balance, and falls and fear of falling after stroke when compared to Knowledge of Performance (Real-time feedback with instructions on how to adjust/ direct cues); the literature is mixed regarding biomechanical balance measures.
- Electromyography Biofeedback During Single Support Phase may be beneficial for improving activities of daily living, functional mobility, and balance after stroke when compared to Stance Phase.
- Weight support feedback cane (WSFC) gait training + conventional care may be beneficial for improving biomechanical gait measures and neurophysiological measures, but not gait speed, after stroke when compared to Regular cane gait training + conventional care.
- 100% performance feedback and scatter plot visual feedback may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to No performance feedback.
- Multimodal training: Biofeedback FES +cycling training + biofeedback platform-based balance training + conventional rehabilitation may not be beneficial for improving biomechanical gait measures, muscle strength, activities of daily living, gait speed, gait endurance, balance, and falls and fear of falling after stroke when compared to Conventional rehabilitation.
- EMG biofeedback from the affected-side soleus muscle (EMG) may not be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to Physical therapy (PT).
- Visual Deprivation Group Balance Training Group with Conventional Therapy may be beneficial for improving biomechanical balance measures, but not balance, after stroke when compared to Conventional Therapy.
- Visual Deprivation Group Balance Training Group with Conventional Therapy may be beneficial for improving biomechanical balance measures and functional mobility after stroke when compared to Visual Feedback Balance Training Group with Conventional Therapy.
- Dynamic sitting excercises in the mediolateral and anteroposterior directions with computer visual feedback with 500 (ms) delay may not be beneficial for improving motor recovery, neurophysiological measures, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Dynamic sitting excercises in the mediolateral and anteroposterior directions with computer visual feedback in real time.
- Pressure sensor-based vibrotactile biofeedback may be beneficial for improving biomechanical balance measures and gait speed after stroke when compared to Standing without biofeedback.
- Visual feedback via Mirror with Verbal feedback and Conventional treatment (static and dynamic balance training) may be beneficial for improving balance after stroke when compared to Visual feedback via Mirror with Conventional treatment (static and dynamic balance training).
- Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may be beneficial for improving motor recovery, biomechanical balance measures, spasticity, and range of motion, but not balance, after stroke when compared to Sham Radial

Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy; the literature is mixed regarding functional mobility.

- Whole-Body Tilting Postural Training (Visual feedback monitor with Trunk sensor, 8- direction body tilt and Spine balance 3D) may be beneficial for improving motor recovery, activities of daily living, and balance after stroke when compared to General Postural Training.
- Neurofeedback facilitation with motor imagery may be beneficial for improving functional mobility and balance, but not motor recovery, activities of daily living, and gait speed, after stroke when compared to Sham neurofeedback with motor imagery.
- 3D balance training using visual feedback with Conventional therapy may be beneficial for improving biomechanical gait measures, gait speed, balance, and falls and fear of falling after stroke when compared to Conventional therapy.
- Posturographic platform biofeedback training may be beneficial for improving functional mobility and balance after stroke when compared to hospital treatment.
- Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit) may be beneficial for improving balance, but not biomechanical gait measures, after stroke when compared to Trunk stabilization exercises; the literature is mixed regarding muscle strength.
- Gaming Assisted Visual feedback for balance training with Conventional therapy may be beneficial for improving biomechanical gait measures after stroke when compared to Balance training exercises with Conventional therapy; the literature is mixed regarding biomechanical balance measures, range of motion, and balance.
- Wii Fit balance training may not be beneficial for improving balance after stroke when compared to Tetrax biofeedback balance training.
- Smartphone visual feedback for trunk control training with Conventional care may be beneficial for improving functional mobility and balance after stroke when compared to Conventional care.
- Balance training using Biodex stability system with visual biofeedback may not be beneficial for improving biomechanical balance measures and balance after stroke when compared to Balance training.
- Treadmill training with Rhythmic auditory feedback may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Treadmill training.
- Balance training with postural control visual biofeedback and conventional rehabilitation may be beneficial for improving functional mobility and balance, but not activities of daily living, after stroke when compared to Conventional rehabilitation.
- Space balance 3D training using visual feedback program with Conventional rehabilitation may not be beneficial for improving functional mobility and balance after stroke when compared to Conventional rehabilitation.
- Stepper Exercise with Visual Feedback (with mirror) may be beneficial for improving gait speed, but not functional mobility, after stroke when compared to Stepper Exercise; the literature is mixed regarding muscle strength.
- Botulinum Toxin A injection (under ultrasound guidance) with electromyography biofeedback treatment and conventional care may not be beneficial for improving biomechanical gait measures, spasticity, and gait speed after stroke when compared to Botulinum Toxin A injection (under ultrasound guidance) with conventional care.
- Balance Platform Training with Audio-visual Feedback with Rehabilitation program may not be beneficial for improving biomechanical balance measures, activities of daily living, functional mobility, and balance after stroke when compared to Rehabilitation program with postural training with physiotherapy.
- Balance training with postural control visual biofeedback (SMART Balance master) may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional physical therapy with balance training.
- Balance training with postural control visual biofeedback may be beneficial for improving balance after stroke when compared to Conventional physiotherapy.
- Balance training with self- controlled postural control visual biofeedback may be beneficial for improving biomechanical balance measures after stroke when compared to Balance training with no control over postural control visual biofeedback.

- Balance training with postural control visual biofeedback from unaffected side and physiotherapy may not be beneficial for improving motor recovery, spasticity, functional mobility, and balance after stroke when compared to Stand-up task with physiotherapy.
- 3D balance exercises (3D Thera-Balance) with visual feedback may be beneficial for improving balance, but not gait speed, after stroke when compared to Weight shifting exercises.
- Usual rehabilitation with Sit-to- Stand training and visual feedback may not be beneficial for improving functional mobility after stroke when compared to Usual rehabilitation with Arm task training; the literature is mixed regarding biomechanical balance measures.
- Balance Training with a kinaesthetic ability training (KAT) device (postural control visual biofeedback) may be beneficial for improving biomechanical balance measures, but not motor recovery and activities of daily living, after stroke when compared to Conventional rehabilitation.
- Balance training with force platform biofeedback and Conventional rehabilitation may not be beneficial for improving motor recovery, activities of daily living, and functional mobility after stroke when compared to Conventional rehabilitation.
- Force platform biofeedback balance training with Conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Conventional rehabilitation.
- Balance training with postural control visual biofeedback (SMART Balance master) may not be beneficial for improving biomechanical balance measures, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Conventional rehabilitation.
- Trunk postural control training with visual and auditory feedback with Conventional neurorehabilitation may be beneficial for improving functional mobility and balance, but not muscle strength, spasticity, and activities of daily living, after stroke when compared to Conventional neurorehabilitation.
- Physical therapy with visual biofeedback (SMART Balance master forceplate) may not be beneficial for improving functional mobility and balance after stroke when compared to Physical therapy.
- Balance training with Visual feedback may not be beneficial for improving biomechanical balance measures, gait speed, functional mobility, and balance after stroke when compared to Balance training with Verbal and tactile cues.
- Visual feedback with Nottingham Balance Platform training and physical therapy may be beneficial for improving motor recovery, biomechanical gait measures, biomechanical balance measures, and balance after stroke when compared to Sham visual feedback with Nottingham Balance Platform training and physical therapy.
- Standing practice with Force platform biofeedback may be beneficial for improving biomechanical gait measures after stroke when compared to Standing training table.
- Continuous Auditory Feedback During Sit-to-Stand Training may be beneficial for improving motor recovery, biomechanical balance measures, and functional mobility, but not activities of daily living, after stroke when compared to No Feedback During Sit-to- stand Training.
- Gait training with functional electrical stimulation may be beneficial for improving range of motion after stroke when compared to care; the literature is mixed regarding biomechanical gait measures.
- Visual biofeedback providing posture information may be beneficial for improving biomechanical balance measures after stroke when compared to Standing without biofeedback.
- Pressure sensor-based vibrotactile biofeedback may be beneficial for improving biomechanical balance measures after stroke when compared to Visual biofeedback providing posture information.
- Constant-force EMG- biofeedback Tibalis anterior training with general Physiotherapy may be beneficial for improving muscle strength after stroke when compared to Upper extremity exercise with general Physiotherapy.
- Visual biofeedback training with Conventional rehabilitation may be beneficial for improving biomechanical balance measures after stroke when compared to Conventional rehabilitation.
- Variable-force EMG- biofeedback Tibalis anterior training with general Physiotherapy may be beneficial for improving muscle strength after stroke when compared to Upper extremity exercise with general Physiotherapy.

Summary of Key Points: Biofeedback

Intervention	Control(s)	Function domain(s)	Effect
Gait Training with Visual Feedback	Gait Training or Conventional Therapy	Biomechanical gait measures, activities of daily living	+
Gait Training with Visual Feedback	Gait Training or Conventional Therapy	Motor recovery, muscle strength, range of motion, gait speed, gait endurance, functional mobility, balance, falls and fear of falling	−
Treadmill Training with Visual Biofeedback	Treadmill Training	Biomechanical gait measures, biomechanical balance measures, range of motion, activities of daily living, gait speed, functional mobility	−
Treadmill Training with Visual Biofeedback	Treadmill Training	Gait endurance, balance	=
Gait Training with Activity Feedback	Gait Training or Conventional Therapy	Biomechanical gait measures, gait speed, gait endurance, quality of life	−
Gait Training with Activity Feedback	Gait Training or Conventional Therapy	Functional mobility	=
Gait Training with Postural Control Visual Feedback	Gait Training or electromyography Biofeedback	Biomechanical gait measures	+
Gait Training with Postural Control Visual Feedback	Gait Training or electromyography Biofeedback	Biomechanical balance measures, muscle strength, aerobic measures, functional mobility, balance, quality of life	−
Gait Training with Postural Control Visual Feedback	Gait Training or electromyography Biofeedback	Gait speed	=
Trunk Training with Visual Biofeedback	Conventional Therapy	Gait speed, functional mobility, balance	+
Trunk Training with Visual Biofeedback	Conventional Therapy	Biomechanical gait measures	−
Trunk Training with Visual Biofeedback	Conventional Therapy	Muscle strength	=
Rehabilitation with electromyography biofeedback	Conventional Therapy	Neurophysiological measures	+
Rehabilitation with electromyography biofeedback	Conventional Therapy	Motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, sensory and proprioceptive function, activities of daily living, gait speed, gait endurance	−
Rehabilitation with electromyography biofeedback	Conventional Therapy	Biomechanical balance measures, functional mobility	=
Constant-force electromyography-biofeedback Tibalis anterior training with general Physiotherapy	Variable-force electromyography-biofeedback Tibalis anterior training with general Physiotherapy	Muscle strength, gait speed, gait endurance, functional mobility	−
Constant-force electromyography-biofeedback Tibalis anterior training with general Physiotherapy	Variable-force electromyography-biofeedback Tibalis anterior training with general Physiotherapy	Biomechanical balance measures	=
Galvanic vestibular stimulation	Lokomat gait training or Physiotherapy with visual feedback	Balance	−

Lokomat gait training	Physiotherapy with visual feedback	Balance	=
Balance Training with Computer-based Visual Feedback	Mirror Feedback	Motor recovery, balance	+
Cycling Training with Biofeedback	Conventional Rehabilitation	Motor recovery, spasticity, gait speed, gait endurance	+
Overground Gait Training with Auditory Feedback	Gait Training	Biomechanical gait measures, neurophysiological measures, gait speed	+
Overground Gait Training with Auditory Feedback	Gait Training	Gait endurance, functional mobility, balance	−
Gait training with auditory feedback caused by active weight bearing on their paralyzed foot	General gait training over the ground	Biomechanical balance measures, gait speed, functional mobility	+
Verbal Cues and Feedback During Walking	Tactile Cues and Feedback During Walking	Gait speed	+
Verbal Cues and Feedback During Walking	Tactile Cues and Feedback During Walking	Biomechanical gait measures, neurophysiological measures	−
Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy	Sit-to-stand Training with physiotherapy	Muscle strength, gait speed, functional mobility, balance, quality of life	+
Standing postural symmetry training with a visual and auditory biofeedback trainer with repetitive sit-to-stand training and conventional rehabilitation	Conventional rehabilitation	Biomechanical balance measures, falls and fear of falling	−
Balance Training with Biofeedback	Balance Training or Conventional Therapy	Biomechanical balance measures, range of motion, sensory and proprioceptive function, gait speed, functional mobility, balance	+
Balance Training with Biofeedback	Balance Training or Conventional Therapy	Biomechanical gait measures, activities of daily living	−
Balance Training with Biofeedback	Balance Training or Conventional Therapy	Motor recovery, muscle strength	=
Visual feedback with Unstable surface balance training	Unstable surface balance training	Functional mobility, balance	+
Visual feedback with Unstable surface balance training	Unstable surface balance training	Biomechanical gait measures, gait speed	−
Visual feedback with Unstable surface balance training	Unstable surface balance training	Range of motion	=
Rehabilitation with Balance training and Visual biofeedback	rehabilitation program with lateral wedge insole	Functional mobility, balance	−
Target or Reach Visual Feedback Training	Conventional Rehabilitation	Biomechanical balance measures, neurophysiological measures	+
Target or Reach Visual Feedback Training	Conventional Rehabilitation	Gait speed, balance	−
Strength Training with Visual Feedback	Physical Therapy	Motor recovery, muscle strength	+
Strength Training with Visual Feedback	Physical Therapy	Gait speed, balance	−
Strength Training with Visual Feedback	Physical Therapy	Sensory and proprioceptive function	=

Perceptual Feedback	Conventional Treatment	Balance	+
Perceptual Feedback	Conventional Treatment	Biomechanical balance measures	–
Robot-Assisted Gait Training with Biofeedback	No Biofeedback or Conventional Biofeedback	Neurophysiological measures	+
Robot-Assisted Gait Training with Biofeedback	No Biofeedback or Conventional Biofeedback	Biomechanical gait measures, spasticity, pain, activities of daily living, functional mobility, balance, quality of life	–
Robot-Assisted Gait Training with Biofeedback	No Biofeedback or Conventional Biofeedback	Motor recovery	=
Visual Biofeedback with Orthotic Devices	Sham Feedback	Spasticity	+
Visual Biofeedback with Orthotic Devices	Sham Feedback	Range of motion	–
Visual Biofeedback with Orthotic Devices	Sham Feedback	Gait speed	=
Neurofeedback	Sham	Biomechanical gait measures, sensory and proprioceptive function, gait speed, functional mobility	+
Knowledge of Results (Real-time visual feedback)	Knowledge of Performance (Real-time feedback with instructions on how to adjust/ direct cues)	Motor recovery, gait speed, balance, falls and fear of falling	–
Knowledge of Results (Real-time visual feedback)	Knowledge of Performance (Real-time feedback with instructions on how to adjust/ direct cues)	Biomechanical balance measures	=
Electromyography Biofeedback During Single Support Phase	Stance Phase	Activities of daily living, functional mobility, balance	+
Weight support feedback cane (WSFC) gait training + conventional care	Regular cane gait training + conventional care	Biomechanical gait measures, neurophysiological measures	+
Weight support feedback cane (WSFC) gait training + conventional care	Regular cane gait training + conventional care	Gait speed	–
100% performance feedback and scatter plot visual feedback	No performance feedback	Biomechanical gait measures, gait speed	–
Multimodal training: Biofeedback FES +cycling training + biofeedback platform-based balance training + conventional rehabilitation	Conventional rehabilitation	Biomechanical gait measures, muscle strength, activities of daily living, gait speed, gait endurance, balance, falls and fear of falling	–
EMG biofeedback from the affected-side soleus muscle (EMG)	Physical therapy (PT)	Biomechanical gait measures, range of motion, gait speed	–
Visual Deprivation Group Balance Training Group with Conventional Therapy	Conventional Therapy	Biomechanical balance measures	+
Visual Deprivation Group Balance Training Group with Conventional Therapy	Conventional Therapy	Balance	–
Visual Deprivation Group Balance Training Group with Conventional Therapy	Visual Feedback Balance Training Group with Conventional Therapy	Biomechanical balance measures, functional mobility	+

Dynamic sitting excercises in the mediolateral and anteroposterior directions with computer visual feedback with 500 (ms) delay	Dynamic sitting excercises in the mediolateral and anteroposterior directions with computer visual feedback in real time	Motor recovery, neurophysiological measures, activities of daily living, gait speed, functional mobility, balance	–
Pressure sensor-based vibrotactile biofeedback	Standing without biofeedback	Biomechanical balance measures, gait speed	+
Visual feedback via Mirror with Verbal feedback and Conventional treatment (static and dynamic balance training)	Visual feedback via Mirror with Conventional treatment (static and dynamic balance training)	Balance	+
Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Motor recovery, biomechanical balance measures, spasticity, range of motion	+
Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Balance	–
Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Functional mobility	=
Whole-Body Tilting Postural Training (Visual feedback monitor with Trunk sensor, 8- direction body tilt and Spine balance 3D)	General Postural Training	Motor recovery, activities of daily living, balance	+
Neurofeedback facilitation with motor imagery	Sham neurofeedback with motor imagery	Functional mobility, balance	+
Neurofeedback facilitation with motor imagery	Sham neurofeedback with motor imagery	Motor recovery, activities of daily living, gait speed	–
3D balance training using visual feedback with Conventional therapy	Conventional therapy	Biomechanical gait measures, gait speed, balance, falls and fear of falling	+
Posturographic platform biofeedback training	hospital treatment	Functional mobility, balance	+
Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit)	Trunk stabilization exercises	Balance	+
Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit)	Trunk stabilization exercises	Biomechanical gait measures	–
Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit)	Trunk stabilization exercises	Muscle strength	=
Gaming Assisted Visual feedback for balance training with Conventional therapy	Balance training exercises with Conventional therapy	Biomechanical gait measures	+
Gaming Assisted Visual feedback for balance training with Conventional therapy	Balance training exercises with Conventional therapy	Biomechanical balance measures, range of motion, balance	=
Wii Fit balance training	Tetrax biofeedback balance training	Balance	–
Smartphone visual feedback for trunk control training with Conventional care	Conventional care	Functional mobility, balance	+

Balance training using Biodex stability system with visual biofeedback	Balance training	Biomechanical balance measures, balance	–
Treadmill training with Rhythmic auditory feedback	Treadmill training	Biomechanical gait measures, gait speed, functional mobility	+
Balance training with postural control visual biofeedback and conventional rehabilitation	Conventional rehabilitation	Functional mobility, balance	+
Balance training with postural control visual biofeedback and conventional rehabilitation	Conventional rehabilitation	Activities of daily living	–
Space balance 3D training using visual feedback program with Conventional rehabilitation	Conventional rehabilitation	Functional mobility, balance	–
Stepper Exercise with Visual Feedback (with mirror)	Stepper Exercise	Gait speed	+
Stepper Exercise with Visual Feedback (with mirror)	Stepper Exercise	Functional mobility	–
Stepper Exercise with Visual Feedback (with mirror)	Stepper Exercise	Muscle strength	=
Botulinum Toxin A injection (under ultrasound guidance) with electromyography biofeedback treatment and conventional care	Botulinum Toxin A injection (under ultrasound guidance) with conventional care	Biomechanical gait measures, spasticity, gait speed	–
Balance Platform Training with Audio-visual Feedback with Rehabilitation program	Rehabilitation program with postural training with physiotherapy	Biomechanical balance measures, activities of daily living, functional mobility, balance	–
Balance training with postural control visual biofeedback (SMART Balance master)	Conventional physical therapy with balance training	Motor recovery, activities of daily living	–
Balance training with postural control visual biofeedback	Conventional physiotherapy	Balance	+
Balance training with self- controlled postural control visual biofeedback	Balance training with no control over postural control visual biofeedback	Biomechanical balance measures	+
Balance training with postural control visual biofeedback from unaffected side and physiotherapy	Stand-up task with physiotherapy	Motor recovery, spasticity, functional mobility, balance	–
3D balance exercises (3D Thera-Balance) with visual feedback	Weight shifting exercises	Balance	+
3D balance exercises (3D Thera-Balance) with visual feedback	Weight shifting exercises	Gait speed	–
Usual rehabilitation with Sit-to- Stand training and visual feedback	Usual rehabilitation with Arm task training	Functional mobility	–
Usual rehabilitation with Sit-to- Stand training and visual feedback	Usual rehabilitation with Arm task training	Biomechanical balance measures	=
Balance Training with a kinaesthetic ability training (KAT) device (postural control visual biofeedback)	Conventional rehabilitation	Biomechanical balance measures	+
Balance Training with a kinaesthetic ability training (KAT) device (postural control visual biofeedback)	Conventional rehabilitation	Motor recovery, activities of daily living	–

Balance training with force platform biofeedback and Conventional rehabilitation	Conventional rehabilitation	Motor recovery, activities of daily living, functional mobility	–
Force platform biofeedback balance training with Conventional rehabilitation	Conventional rehabilitation	Biomechanical gait measures, gait speed	–
Balance training with postural control visual biofeedback (SMART Balance master)	Conventional rehabilitation	Biomechanical balance measures, activities of daily living, gait speed, functional mobility, balance	–
Trunk postural control training with visual and auditory feedback with Conventional neurorehabilitation	Conventional neurorehabilitation	Functional mobility, balance	+
Trunk postural control training with visual and auditory feedback with Conventional neurorehabilitation	Conventional neurorehabilitation	Muscle strength, spasticity, activities of daily living	–
Physical therapy with visual biofeedback (SMART Balance master forceplate)	Physical therapy	Functional mobility, balance	–
Balance training with Visual feedback	Balance training with Verbal and tactile cues	Biomechanical balance measures, gait speed, functional mobility, balance	–
Visual feedback with Nottingham Balance Platform training and physical therapy	Sham visual feedback with Nottingham Balance Platform training and physical therapy	Motor recovery, biomechanical gait measures, biomechanical balance measures, balance	+
Standing practice with Force platform biofeedback	Standing training table	Biomechanical gait measures	+
Continuous Auditory Feedback During Sit-to-Stand Training	No Feedback During Sit-to- stand Training	Motor recovery, biomechanical balance measures, functional mobility	+
Continuous Auditory Feedback During Sit-to-Stand Training	No Feedback During Sit-to- stand Training	Activities of daily living	–
Gait training with functional electrical stimulation	care	Range of motion	+
Gait training with functional electrical stimulation	care	Biomechanical gait measures	=
Visual biofeedback providing posture information	Standing without biofeedback	Biomechanical balance measures	+
Pressure sensor-based vibrotactile biofeedback	Visual biofeedback providing posture information	Biomechanical balance measures	+
Constant-force EMG- biofeedback Tibalis anterior training with general Physiotherapy	Upper extremity exercise with general Physiotherapy	Muscle strength	+
Visual biofeedback training with Conventional rehabilitation	Conventional rehabilitation	Biomechanical balance measures	+
Variable-force EMG- biofeedback Tibalis anterior training with general Physiotherapy	Upper extremity exercise with general Physiotherapy	Muscle strength	+

Dual-Task Training

Adapted from: https://link.springer.com/chapter/10.1007/978-3-030-23762-2_40

Dual-tasking training requires subjects to simultaneously perform complex tasks, such as cognitive and motor tasks, allowing them to improve their coordination of various tasks (Kim et al., 2014a). Cognitive-motor tasks are important for various activities of daily living, such as walking while holding a conversation (Liu et al. 2017). Additionally, dual tasks can be two motor tasks to allow for different motor processes to occur simultaneously to further stimulate the damaged brain.

A total of 28 RCTs were found that evaluated Dual-Task training for lower extremity motor rehabilitation. Five RCTs compared Cognitive Dual Motor Task with Conventional Therapy or No Treatment (Iqbal et al. 2020; Kannan et al. 2019; Park & Lee 2019; Liu et al. 2017; Yang et al. 2007). Ten RCTs compared Dual Task with Single Task Training or Control (Jung et al. 2023; Plummer et al. 2022; Baek et al. 2021; Fishbein et al. 2019; Meester et al. 2019; Pang et al. 2018; Choi et al. 2015a; Cho et al. 2015b; Shim et al. 2012; Durfee et al. 2011). Four RCTs compared Dual Cognitive-Motor Task with Balance Training (Hong et al. 2020; Choi et al. 2015b; Jiejiao et al. 2012; Seo et al. 2012). One RCT compared Problem-Oriented Willed-Movement Therapy with Conventional Treatment (Tang et al. 2005). One RCT compared Dual-Task and Resistance Exercise with Aerobic and Resistance Exercise (Antonio et al. 2022). One RCT evaluated Dual-task with Various Instructional Sets (Sengar et al. 2019). One RCT compared Cognitive and Motor Dual-Task Training with Motor Imagery (Mishra et al. 2015). One RCT compared Dual-Task Training with Vestibular Rehabilitation (Saleem et al. 2019). One RCT compared Cognitive Task with Motor Task vs No Task in Various Settings (Lord et al. 2006). One RCT compared Cognitive Therapeutic Exercise Combined with Goal-Directed Training with Goal-Directed Training Alone (Abdelfadil et al. 2024). One RCT compared Cognitive Training with Conventional Therapy (Tahoon et al. 2024). One RCT compared Dual-Task Training with Motor Imagery with Dual-Task Training Alone (Zafar et al. 2024).

In addition, three RCTs in which Dual-Task training formed part of a combined or comparative intervention are cross-referenced at the end of Table 16; their primary listings appear in other tables.

The methodological details and results of all 28 RCTs are presented in Table 16.

Table 16. RCTs Evaluating Dual-Task Training for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)

Study design		
Cognitive Dual Motor Task vs Conventional Therapy or No Treatment		
Iqbal et al. (2020) RCT (4) Nstart=64 Nend=64 TPS=Chronic A vs 0	E: Dual task training C: Conventional physiotherapy Duration: 40min/d, 4d/wk, 4wks	E vs C: Timed Up and Go Test (+exp) 10-meter walk test (+exp) Step length (+exp) Stride length (+exp) Cycle time (+exp) Cadence (+exp)
Kannan et al. (2019) RCT (4) Nstart=25 Nend=23 TPS=Chronic A vs 0 Also in Table 26 (Virtual Reality)	E: Cognitive motor exergaming training C: Conventional training (stretching, strengthening, balance and endurance training) Duration: 90min/d, 10d, 6wk	E vs C: Limit of Stability (+exp) Movement velocity (+exp) Postural center of mass (-) Letter-number sequencing (No stats) 10min Walk test (No stats) Berg balance scale (No stats) 6min Walk test (No stats) Timed Up and Go (No stats) Wii Gaming scores (-)
Park & Lee (2019c) RCT (6) Nstart=30 Nend=30 TPS=Chronic A vs 0	E: Cognitive-motor dual task program C: Conventional occupational therapy Duration: 30min/d, 3dwk, for 6wks	E vs C: Fugl-Meyer Assessment (-) Modified Functional Reach Test Forward (-) Affected (-) Nonaffected (-) Berg Balance Scale (+exp) Trail Making Test A (-) B (-) Digit Span Test Forward (+exp) Backward (+exp) Stroop Test Colour (+exp) Word (-)
Liu et al. (2017) RCT (5) Nstart=28 Nend=28 TPS=Chronic A vs A + B vs 0	E1: Cognitive dual task training (Gait training + cognitive task) E2: Motor dual task training (Gait training + motor task) C: Conventional therapy Duration: 30min/d, 3d/wk for 4wk	E1 vs E2/C: Gait speed (-) Cadence (+exp1) Stride time (-) Stride length (-)
Yang et al. (2007) RCT (7) Nstart=25 Nend=25 TPS=Chronic A vs B	E: Dual-task based training (ball exercise) C: No intervention Duration: 30min/d, 3d/wk for 4wk	E vs C: Single-Task Measures 10-m walk Speed (+exp) Cadence (+exp) Stride time (+exp) Stride length (+exp) Temporal symmetry index (-) Dual-Task Measures 10-m walk Speed (+exp) Cadence (-) Stride time (+exp)

		Stride length (+exp) Temporal symmetry index (-)
Dual Task vs Single Task Training or Control		
Jung et al. (2023) RCT (9) Nstart=34 Nend=28 TPS=Subacute A vs B	E: Dual-task walking C: Overground walking Duration: 6min 2x/d, 3d/wk, 4wks	E vs C: 10MWT (-) 6MWT (-) TUG (-) BBS (-) ABC-K (+exp)
Plummer et al. (2022) RCT (8) Nstart=37 Nend=36 TPS=Chronic A vs B	E1: Dual-task gait training C: Single-task gait training Duration: 30min/d, 3d/wk, for 4wks	E1 vs C: Single-task Gait speed (preferred/fast) (-) Dual-task Stroop Gait speed (preferred/fast) (-) Dual-task clock Gait speed (preferred/fast) (-) 10-m walk speed (-) Timed Up and Go (-) Lower Extremity Fugl-Meyer (-) Activities-specific Balance Confidence scale (-) Stroke Impact Scale (-) Computerized Stroop, reaction time interference (-) Computerized Stroop, accuracy interference (+exp)
Baek et al. (2021) RCT (7) Nstart=34 Nend=31 TPS=Chronic A1 vs A2 Also in Table 9 (Treadmill Training)	E: Dual-task gait training with treadmill C: Single-task gait training with treadmill Duration: 30min, 2d/wk, 6wks	E vs C: Gait Measures in Single-task Condition Speed (-) Stride Length (-) Stance Phase Variability (-) Cadence (-) Correct response rate (-) Gait Measures in Dual-task Condition Speed (+exp) Stride Length (+exp) Stance Phase Variability (+exp) Cadence (-) Correct response rate (-) Dual-task Cost-motor task Speed (+exp) Stride Length (-) Stance Phase Variability (+exp) Cadence (-) Dual-task Cost-cognition task (-) Fall Efficacy Scale (-)

(2019) RCT (6) Nstart=22 Nend=22 TPS=Chronic A vs B Also in Table 9 (Treadmill Training); Table 26 (Virtual Reality)	E: Dual-task (VR-based UL training while walking on treadmill) C: Single task treadmill walking	E vs C: 10 m walk test Time (+exp) Steps (+exp) Timed Up and Go (-) Functional Reach Test (+exp) Lateral Reach Test (+exp)

		Activities Specific Balance confidence (+exp) Berg Balance Scale (+exp)
Meester et al. (2019) RCT (6) Nstart=50 Nend=43 TPS=Chronic A vs B	E: Walking training with simultaneous cognitive demand (dual task) C: Treadmill walking training Duration: 30min/d, 2d/wk, 10wks	E vs C: 2-Minute Walk Test Distance (-) Distance with dual task (-) Walking distance change (-) Number of cognitive responses (-) Step activity (-) Physical Activity Scale for Elderly (-) SF-36 (-) EQ-5D (-) Community walking confidence (-)
Pang et al. (2018) RCT (8) Nstart=84 Nend=78 TPS=Chronic A1 vs A2 vs B	E1: Dual-task balance/mobility E2: Single-task balance/mobility C: Upper limb exercise Duration: 60min/d, 3d/wk, for 8wks	E1 vs E2/C: Percent dual-task effect(%DTE) in walking time When forward walking + verbal fluency (+exp1) When forward walking + serial-3-subtractions (+exp1) When TUG + verbal fluency (+exp1) When TUG + serial-3-subtractions (-) %DTE in correct response rate When forward walking + verbal fluency (-) When forward walking+ serial-3-subtractions (-) When TUG + verbal fluency (-) When TUG + serial-3-subtractions (-) Activities-specific Balance Confidence Scale (-) Frenchay Activities Index (-) Stroke-specific Quality of Life Scale (-) E2 v C: DTE%-all tasks (-) DTE% in correct response rate-all tasks (-) Activities-specific Balance Confidence Scale (-) Frenchay Activities Index (-) Stroke-specific Quality of Life Scale (-)
Choi et al. (2015a) RCT (7) Nstart=37 Nend=37 TPS=Chronic A vs B Also in Table 9 (Treadmill Training)	E: Cognitive-motor dual task training while treadmill walking + Conventional rehabilitation C: Single task training on Treadmill walking + Conventional rehabilitation Duration: 15min/d, 3d/wk, 4wk task training & 5d/wk, 4wk conventional rehabilitation	E vs C: Static Balance Anteroposterior sway velocity with eyes open (-) Mediolateral sway velocity with eyes open (+exp) Anteroposterior sway velocity with eyes closed (+exp) Mediolateral sway velocity with eyes closed (+exp) Timed Up & Go Test (-)
Cho et al. (2015b) RCT (8) Nstart=24	E: Virtual reality with cognitive load + conventional rehabilitation C: Treadmill walking with virtual environment + conventional rehabilitation	E vs C: Under single task condition Gait velocity (-)

Nend=22 TPS=Chronic A vs B Also in Table 26 (Virtual Reality)	Duration: 30min/d, 5d/wk, 4wk Virtual reality training and 60min/d, 5d/wk, 4wk conventional therapy	Cadence (-) Paretic side step length (-) Stride length (-) Under dual task condition Gait velocity (+exp) Cadence (+exp) Paretic side step length (+exp) Stride length (+exp)
Shim et al. (2012) RCT (5) Nstart=35 Nend=33 TPS=Chronic A vs 0	E: Motor dual task training + conventional therapy C: Conventional therapy Duration: 30min/d, 3d/wk for 6wks dual task training & 30min/d, 5d/wk, for 6wks conventional physical therapy	E vs C: Gait speed (+exp) Cadence (+exp) Stride length (+exp) Step length (+exp) Single limb support (+exp) Double limb support (-)
Durfee et al. (2011) RCT (4) Nstart=19 Nend=16 TPS=Chronic A + B vs A	E: Ankle movements + following a target waveform (cognitively demanding task) C: Ankle movements Duration: 180 movements/d, 5d/wk, for 4wks	E vs C: Ankle DF/PF angle (+exp) Clearance (-) Gait temporal symmetry ratio (-) Stride length (-) 10-Meter Walking Test (-) Cortical activation by fMRI (-)
Dual Cognitive-Motor Task vs Balance Training		
Hong et al. (2020) RCT (4) Nstart=24 Nend=17 TPS=Chronic A1 vs A2	E: Dual task of balance and cognition C: Balance training Duration: 30min/d, 3d/wk, 4wks	E vs C: Timed Up and Go (+exp) Berg Balance scale (-) Stride velocity (-) Stride length (-) Double support time (-)
Choi et al. (2015b) RCT (5) Nstart=21 Nend=21 TPS=Subacute A + B vs A Also in Table 11 (Balance Training)	E: Balance training + cognitive training C: Balance training with balance board Duration: 1hr/d, 3d/wk for 4wk	E vs C: Berg Balance Scale (-) Fugl-Meyer Assessment (-) Modified Barthel Index (-)
Jiejiao et al. (2012) RCT (8) Nstart=92 Nend=85 TPS=Chronic A + B vs A Also in Table 11 (Balance Training)	E: Balance training + cognitive training C: Balance training Duration: 40min/d, 5d/wk for 8wks	E vs C: Center of Pressure (-) Mediolateral Sway Distance (+exp) Anteroposterior Eyes Open (+exp) Eyes Closed (-)
Seo et al. (2012) RCT (4) Nstart=40 Nend=40 TPS=Chronic A vs B Also in Table 11 (Balance Training)	E: Dual-task balance training C: Single-task balance training Duration: 30min/d, 5d/wk for 4wks	E vs C: Sway path (-) Sway area (+exp) Max velocity (+exp)

Problem-Oriented Willed-Movement Therapy vs Conventional Treatment		
Tang et al. (2005) RCT (6) Nstart=48 Nend=47 TPS=Subacute A vs B	E: Problem-oriented willed- movement therapy C: Neurodevelopmental treatment Duration: 50min/d, 5-6d/wk, for 8wks	E vs C: Rehabilitation Assessment of Movement (+exp) Upper Extremity (+exp) Lower Extremity (+exp) Basic Mobility (+exp) Mini-Mental State Examination (-)
Dual-Task vs Aerobic and Resistance Exercise		
Antonio et al. (2022) RCT (8) Nstart=26 Nend=26 TPS=Chronic A vs B Also in Table 21 (Strength and Resistance Training)	E: Dual Task (Consisting aerobic and resistance exercises while performing cognitive task) C: Aerobic and Resistance Exercises, without Performing Cognitive Task Duration: 60–90min, 2d/wk, 15wks	E vs C: Timed-up-and-go Test (+exp) Cognitive Performance in TUG Dual Task (-) Dual Task Cost in in TUG (-) 10-M Walk Test (-) 10MWT Dual Task (-) Cognitive Performance in 10MWT Dual Task (-) Dual Task Cost in 10MWT (-) 6-M Walk Test (-) Maximum Ballistic Voluntary Isometric Contraction (-) Montreal Cognitive Assessment (-) Falls Efficacy Scale (FES-I) (-) Stroke Impact Scale (-) Mini-BESTest (-)
Dual-task with Various Instructional Sets		
Sengar et al. (2019) RCT (4) Nstart=30 Nend=30 TPS=Chronic A1 vs A2	E: Dual-task training with variable priority instructional sets C: Dual-task training with fixed priority instructional sets Duration: 45min/d, 3d/wk, for 4wks	E vs C: 10-m walk test Comfortable speed (+exp) Maximal speed (+exp) Step length (+exp) Stride Length (+exp)
Cognitive and Motor Dual-Task Training vs Motor Imagery		
Mishra et al. (2015) RCT (5) Nstart=15 Nend=15 TPS=Not reported A1 vs A2 vs B Also in Table 17 (Mental Practice)	E1: Motor dual task training + Conventional care E2: Cognitive dual task training + Conventional care E3: Motor imagery + Conventional care Duration: 15min/session, 5d/wk for 2wks	E1 v E2/E3: Berg Balance scale (-) Functional gait assessment scale (+exp1)
Dual-Task Training vs Vestibular Rehabilitation		
Saleem et al. (2019) RCT (4) Nstart=30 Nend=30 TPS=Subacute A vs B	E: Vestibular Rehabilitation + Conventional PT C: Dual Task training + Conventional PT Duration: 45min/d, 3d/wk, 4wks interventions & 45min/d, 5d/wk, 4wks Conventional PT	E vs C: Wisconsin Gait Scale (+exp) Mini-BEST (+exp)
Cognitive Task vs Motor Task vs No Task in Various Settings		
Lord et al. (2006) RCT (6)	E1: No task in suburban street E2: Cognitive task in suburban street	E1 vs E2 vs E3 vs E4 vs E5 vs E6 vs C1 vs C2 vs C3:

Nstart=27 Nend=27 TPS=Chronic A1 vs A2 vs A3 vs B1 vs B2 vs B3 vs A4 vs C1 vs C2	E3: Motor task in suburban street E4: No task in shopping mall E5: Cognitive task in shopping mall E6: Motor task in shopping mall C1: No task in clinic C2: Motor task in clinic C3: cognitive task in clinic Duration: 6 min walk	6-minute walk test (-) Cadence (-) Step Length (-)
Cognitive Therapeutic Exercise Combined with Goal-Directed Training vs Goal-Directed Training Alone		
Abdelfadil et al. (2024) RCT (7) Nstart=40 Nend=40 TPS=Chronic A + B vs B	E: Systematic desensitzation + goal-directed paradigm C: Goal-directed paradigm Duration: E: 90 mins/d (20 mins of Jacobson's technique + 30 mins of guided imagery training + 40 mins of goal-directed paradigm training), 3ds/wk, 8wks; C: 40 mins/d, 3ds/wk, 8wks	E vs C: TUG (+exp) Dynamic gait index (+exp) Berg balance scale (+exp) Biodex Fall Risk Index (+exp) 16-item fall efficacy scale-international (+exp)
Cognitive Training vs Conventional Therapy		
Tahoon et al. (2024) RCT (7) Nstart=40 Nend=40 TPS=Chronic A vs 0	E: Rehacom cognitive training + Conventional physiotherapy C: Conventional physiotherapy Duration: E: 60min Rehacom + 60min Conventional care/d, 3d/wk, 8wks	E vs C: MoCA (+exp) step length (+exp) walking speed (-)
Dual-Task Training with Motor Imagery vs Dual-Task Training Alone		
Zafar et al. (2024) RCT (7) Nstart=30 Nend=29 TPS=Subacute A + B vs A Also in Table 17 (Mental Practice)	E: Dual-task training + motor imagery C: Dual-task training Duration: 28min (7 task x 4min)/d, 8wks	E vs C: Functional Reach Test (-) TUG (+exp) BBS (+exp) Movement Imagery Questionnaire-3 (+exp) internal imagery (+exp) external imagery (+exp) kinesthetic (+exp)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Ahmed et al. (2021) RCT (8) Nstart=84 Nend=84 TPS=Chronic A + B vs A Primary listing: Table 4 (Trunk Training)	E: High-intensity multiplanar trunk training + dual-task training + conventional rehabilitation C: Trunk training + conventional rehabilitation. Duration: 45min/d, 5d/wk for 3mo	E vs C: Trunk Impairment Scale (+exp) Dynamic Control(+exp) Coordination (+exp) Timed-Up-And-Go (+exp) Cognitive (+exp) 10-Metre Walk Test (+exp) Berg Balance Scale (+exp) Stroke Impact Scale (+exp)
Saleh et al. (2019) RCT (6) Nstart=50 Nend=50 TPS=Chronic A1 vs A2 Primary listing: Table 20 (Aquatic Therapy)	E: Aquatic-based Dual-task Motor Training C: Land-based Dual-task Motor Training Duration: 45min, 3d/wk, for 6wks	E vs C: Overall Stability Index (+exp) Anteroposterior Stability Index (+exp) Mediolateral Stability Index (+exp) Walking speed (+exp) Step length affected side (+exp) non affected side (+exp) Support time affected side (+exp)

Kim et al. (2016a) RCT (4) Nstart=20 Nend=NR TPS=Chronic A vs B Primary listing: Table 20 (Aquatic Therapy)	E: Aquatic therapy (Dual-task training with upper extremity tasks) C: Neurodevelopmental techniques Duration: 1h/d, 5d/wk for 6wks	E vs C: Berg Balance Scale (+exp) Five-Time Sit to Stand Test (+exp) Functional Reach Test (+exp) 10-Meter Walk Test (+exp) Timed Up and Go Test (+exp) Functional Gait Assessment (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1b	High-intensity multiplanar trunk training with dual-task training and conventional rehabilitation may produce greater improvements in functional mobility than Trunk training with conventional rehabilitation.	1	Ahmed et al. 2021
2	Aquatic therapy (Dual-task training with upper extremity tasks) may produce greater improvements in functional mobility than Neurodevelopmental techniques.	1	Kim et al. 2016a

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Cognitive Dual Motor Task may not have a difference in efficacy when compared to Conventional Therapy or No Treatment for improving balance.	2	Kannan et al. 2019; Park & Lee 2019c
1a	Dual Task may produce greater improvements in balance than Single Task Training or Control.	2	Jung et al. 2023; Fishbein et al. 2019
2	Dual Cognitive-Motor Task may not have a difference in efficacy when compared to Balance Training for improving balance.	2	Hong et al. 2020; Choi et al. 2015b
1b	Dual-Task and Resistance Exercise may not have a difference in efficacy when compared to Aerobic and Resistance Exercise for improving balance.	1	Antonio et al. 2022
2	Motor dual task training with Conventional care may not have a difference in efficacy when compared to Cognitive dual task training with Conventional care or Motor imagery and Conventional care for improving balance.	1	Mishra et al. 2015
2	Dual-Task Training may produce greater improvements in balance than Vestibular Rehabilitation.	1	Saleem et al. 2019
1b	Cognitive Therapeutic Exercise Combined with Goal-Directed Training may produce greater improvements in balance than Goal-Directed Training Alone.	1	Abdelfadil et al. 2024
1b	Dual-Task Training with Motor Imagery may produce greater improvements in balance than Dual-Task Training Alone.	1	Zafar et al. 2024
1b	High-intensity multiplanar trunk training with dual-task training and conventional rehabilitation may produce greater improvements in balance than Trunk training with conventional rehabilitation.	1	Ahmed et al. 2021
2	Aquatic therapy (Dual-task training with upper extremity tasks) may produce greater improvements in balance than Neurodevelopmental techniques.	1	Kim et al. 2016a

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Dual Task may not have a difference in efficacy when compared to Single Task Training or Control for improving falls and fear of falling.	3	Baek et al. 2021; Fishbein et al. 2019; Pang et al. 2018
1b	Dual-Task and Resistance Exercise may not have a difference in efficacy when compared to Aerobic and Resistance Exercise for improving falls and fear of falling.	1	Antonio et al. 2022
1b	Cognitive Therapeutic Exercise Combined with Goal-Directed Training may produce greater improvements in falls and fear of falling than Goal-Directed Training Alone.	1	Abdelfadil et al. 2024

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Dual Task may not have a difference in efficacy when compared to Single Task Training or Control for improving quality of life.	3	Plummer et al. 2022; Meester et al. 2019; Pang et al. 2018
1b	Dual-Task and Resistance Exercise may not have a difference in efficacy when compared to Aerobic and Resistance Exercise for improving quality of life.	1	Antonio et al. 2022
1b	High-intensity multiplanar trunk training with dual-task training and conventional rehabilitation may produce greater improvements in quality of life than Trunk training with conventional rehabilitation.	1	Ahmed et al. 2021

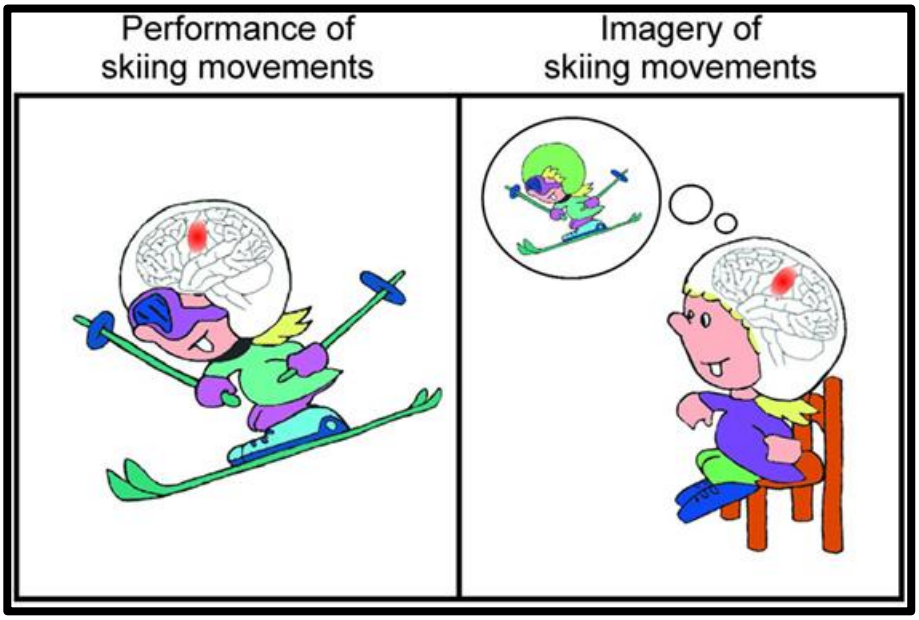
Other Associated Outcome Measures

COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Cognitive Dual Motor Task when compared to Conventional Therapy or No Treatment for improving cognition.	1	Park & Lee 2019c
1b	There is conflicting evidence about the effect of Dual Task when compared to Single Task Training or Control for improving cognition.	1	Plummer et al. 2022
1b	Problem-Oriented Willed-Movement Therapy may not have a difference in efficacy when compared to Conventional Treatment for improving cognition.	1	Tang et al. 2005
1b	Dual-Task and Resistance Exercise may not have a difference in efficacy when compared to Aerobic and Resistance Exercise for improving cognition.	1	Antonio et al. 2022
1b	Cognitive Training may produce greater improvements in cognition than Conventional Therapy.	1	Tahoon et al. 2024

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Problem-Oriented Willed-Movement Therapy may produce greater improvements in upper extremity function than Conventional Treatment.	1	Tang et al. 2005

Key Points

- Cognitive Dual Motor Task may be beneficial for improving biomechanical gait measures and biomechanical balance measures, but not motor recovery, gait endurance, and balance, after stroke when compared to Conventional Therapy or No Treatment; the literature is mixed regarding gait speed and functional mobility.
- Dual Task may be beneficial for improving gait speed and balance, but not motor recovery, biomechanical gait measures, neurophysiological measures, activities of daily living, gait endurance, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Single Task Training or Control.
- Dual Cognitive-Motor Task may be beneficial for improving functional mobility, but not motor recovery, biomechanical gait measures, activities of daily living, and balance, after stroke when compared to Balance Training; the literature is mixed regarding biomechanical balance measures and gait speed.



- Dual-Task and Resistance Exercise may not be beneficial for improving muscle strength, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Aerobic and Resistance Exercise.
- Dual-task training with variable priority instructional sets may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Dual-task training with fixed priority instructional sets.
- Motor dual task training with Conventional care may be beneficial for improving functional mobility, but not balance, after stroke when compared to Cognitive dual task training with Conventional care or Motor imagery and Conventional care.
- Dual-Task Training may be beneficial for improving functional mobility and balance after stroke when compared to Vestibular Rehabilitation.
- Cognitive Task may not be beneficial for improving biomechanical gait measures and gait endurance after stroke when compared to Motor Task or No Task in Various Settings.
- Cognitive Therapeutic Exercise Combined with Goal-Directed Training may be beneficial for improving functional mobility, balance, and falls and fear of falling after stroke when compared to Goal-Directed Training Alone.
- Cognitive Training may be beneficial for improving biomechanical gait measures, but not gait speed, after stroke when compared to Conventional Therapy.
- Dual-Task Training with Motor Imagery may be beneficial for improving functional mobility and balance after stroke when compared to Dual-Task Training Alone.
- High-intensity multiplanar trunk training with dual-task training and conventional rehabilitation may be beneficial for improving gait speed, functional mobility, balance, and quality of life after stroke when compared to Trunk training with conventional rehabilitation.
- Aquatic-based Dual-task Motor Training may be beneficial for improving biomechanical gait measures, biomechanical balance measures, and gait speed after stroke when compared to Land-based Dual-task Motor Training.
- Aquatic therapy (Dual-task training with upper extremity tasks) may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to Neurodevelopmental techniques.

Summary of Key Points: Dual-Task Training

Intervention	Control(s)	Function domain(s)	Effect
Cognitive Dual Motor Task	Conventional Therapy or No Treatment	Biomechanical gait measures, biomechanical balance measures	+
Cognitive Dual Motor Task	Conventional Therapy or No Treatment	Motor recovery, gait endurance, balance	–
Cognitive Dual Motor Task	Conventional Therapy or No Treatment	Gait speed, functional mobility	=
Dual Task	Single Task Training or Control	Gait speed, balance	+
Dual Task	Single Task Training or Control	Motor recovery, biomechanical gait measures, neurophysiological measures, activities of daily living, gait endurance, functional mobility, falls and fear of falling, quality of life	–
Dual Cognitive-Motor Task	Balance Training	Functional mobility	+
Dual Cognitive-Motor Task	Balance Training	Motor recovery, biomechanical gait measures, activities of daily living, balance	–
Dual Cognitive-Motor Task	Balance Training	Biomechanical balance measures, gait speed	=

Dual-Task and Resistance Exercise	Aerobic and Resistance Exercise	Muscle strength, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Dual-task training with variable priority instructional sets	Dual-task training with fixed priority instructional sets	Biomechanical gait measures, gait speed	+
Motor dual task training with Conventional care	Cognitive dual task training with Conventional care or Motor imagery and Conventional care	Functional mobility	+
Motor dual task training with Conventional care	Cognitive dual task training with Conventional care or Motor imagery and Conventional care	Balance	–
Dual-Task Training	Vestibular Rehabilitation	Functional mobility, balance	+
Cognitive Task	Motor Task vs No Task in Various Settings	Biomechanical gait measures, gait endurance	–
Cognitive Therapeutic Exercise Combined with Goal-Directed Training	Goal-Directed Training Alone	Functional mobility, balance, falls and fear of falling	+
Cognitive Training	Conventional Therapy	Biomechanical gait measures	+
Cognitive Training	Conventional Therapy	Gait speed	–
Dual-Task Training with Motor Imagery	Dual-Task Training Alone	Functional mobility, balance	+
High-intensity multiplanar trunk training with dual-task training and conventional rehabilitation	Trunk training with conventional rehabilitation	Gait speed, functional mobility, balance, quality of life	+

Aquatic therapy (Dual-task training with upper extremity tasks)	Neurodevelopmental techniques	Gait speed, functional mobility, balance	+

Mental Practice

Adopted from: https://www.ucbmsh.com/motor-imagery-for-improvement-of-gait-in-stroke-patient/

Mental practice as the name suggests, involves cognitively rehearsing a specific task by repetitively imagining oneself performing the precise movements involved in the task in the absence of performing the physical movement (Page & Peters, 2014). Mental practice is speculated to be effective because of its ability to use the same motor schema as when physically practicing the same task through the activation of similar neural regions and networks during mental practice (Page & Peters, 2014). The use of mental practice was adapted from the field of sports psychology where the technique has been shown to improve athletic performance, when used as an adjunct to standard training methods (Page & Peters, 2014). The technique is believed to be advantageous in stroke survivors because certain motor skills may be difficult to physically practice; stroke survivors spend a majority of their time inactive and alone; and repetitive task- specific practice is a prerequisite for cortical plasticity and subsequent motor changes (Page & Peters, 2014). Mental practice can be used to supplement conventional therapy and can be used at any stage of recovery.

A total of 27 RCTs were found that evaluated mental practice for lower extremity motor rehabilitation. Three RCTs compared Gait Training with Motor Imagery or Mental Practice with Gait Training (Anwar et al. 2022; Sawant 2020; Cho et al. 2013b). One RCT compared Task-Specific Training with Mental Practice with Task-Specific Training (Kumar et al. 2016). Two RCTs compared Task-Specific Training with Mental Practice with Conventional Training or No Treatment (Verma et al. 2011; Malouin et al. 2009). One RCT compared Proprioception Training + Motor Imagery with Proprioception Training (Lee et al. 2015a). One RCT compared Action Observation with Motor Imagery vs Conventional Therapy (Kim et al. 2013). Two RCTs compared Neurofeedback Facilitation with Motor Imagery with Sham (Mihara et al. 2024; Mihara et al. 2021). One RCT compared Mental Practice with Muscle Relaxation (Oostra et al. 2015). Two RCTs compared Circuit Training with Mental Practice with Circuit Training with Education (Aung et al. 2022; Bovonsunthonchai et al. 2020). One RCT compared Mental Imagery with Mental Imagery with Auditory Stimulation (Kim et al. 2011). Eight RCTs compared Mental Imagery with Conventional Training or Sham (Diaz-Lopez et al. 2022; Yin et al. 2021; Dickstein et al. 2013; Braun et al. 2012; Schuster et al. 2012; Hosseini et al. 2012; Bovend'Eerdt et al. 2010; Liu et al. 2004). One RCT compared Body Awareness Therapy with Continuing Usual Daily Activities (Lindvall et al. 2014). One RCT compared Cognitive and Motor Dual-Task Training with Motor Imagery (Mishra et al. 2015). One RCT compared Cognitive Sensory Motor Training with Conventional Therapy (Kim et al. 2021a). One RCT compared Mental Practice with Cognitive Training (Guerra et al. 2022). One RCT compared Motor Imagery with Virtual Reality with Virtual Reality Alone (Masood et al. 2024).

In addition, four RCTs in which mental practice formed part of a combined or comparative intervention are cross-referenced at the end of Table 17; their primary listings appear in other tables.

The methodological details and results of all 27 RCTs are presented in Table 17.

Table 17. RCTs Evaluating Mental Practice for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)
Gait Training with Motor Imagery or Mental Practice vs Gait Training		
Anwar et al. (2022) RCT (6) Nstart=44 Nend=44 TPS=Subacute A vs 0	E: Motor imagery + gait training C: Gait training Duration: 30min/d motor imagery & 30min/d gait training 3d/wk, 6wks	E vs C: 10 metre Walk test (-) Fugl-Meyer Assessment (-) Motor Imagery Questionnaire visual (+exp) kinesthetic (+exp) Imagery/actual walking time ratio (-)
Sawant (2020) RCT (4) Nstart=82 Nend=82 TPS=Not reported A vs B1 vs 0 vs B2	E: Gait training + guided motor imagery + conventional exercises C: Gait training + conventional exercises Duration: E: 20min/d, 3d/wk, 4wks gait training + 10min/d, 3d/wk, 4wks motor imagery C: 30min/d, 3d/wk, 4wks gait training	E vs C: Functional Gait Assessment (+exp) 10-Meter Walk Test (+exp)
Cho et al. (2013b) RCT (7) Nstart=28 Nend=28 TPS=Chronic A vs 0	E: Gait training + Mental practice C: Gait training Duration: 15min/d, mental practice & 30min gait training, 3d/wk, 6wks	E vs C: Fugl-Meyer Assessment (+exp) 10-Metre Walk Test (+exp) Timed Up & Go Test (+exp) Functional Reach Test (+exp)
Task-Specific Training with Mental Practice vs Task-Specific Training		
Kumar et al. (2016) RCT (7) Nstart=40 Nend=40 TPS=Chronic A + B vs A Also in Table 5 (Task-Specific Training)	E: Task-specific training + Mental practice (Motor Imagery) C: Task-specific training Duration: 45-60min/d, 4d/wk for 3wks task-specific training & 15min/d, 4d/wk, for 3wks motor imagery	E vs C: Muscle Strength Hip Flexors (+exp) Hip Extensors (+exp) Knee Flexors (-) Knee Extensors (+exp) Ankle -Dorsiflexors (+exp) Ankle Plantarfelxors (-) 10m walk test (+exp)
Task-Specific Training with Mental Practice vs Conventional Training or No Treatment		
Verma et al. (2011) RCT (8) Nstart=30 Nend=30 TPS=Subacute A + B vs C + A vs D vs C	E: Task-oriented circuit class training + Motor imagery C: Standard rehabilitation based on Bobath techniques Duration: E: 15min/d, 7d/wk, 2wks mental imagery + 25min/d, 7d/wk, 2wks task-oriented circuit class training C: 40min/d, 7d/wk, 2wks standard rehabilitation	E vs C: Functional ambulation category (+exp) Rivermead Visual gait assessment (+exp) Step length asymmetry (-) Cadence (+exp) Stride length asymmetry (-) 10m Walk test Maximum speed (-) Comfortable speed (+exp) 6min Walk test (+exp)
Malouin et al. (2009) RCT (6)	E1: Task-specific training + Mental practice E2 Task-specific training + Cognitive training	E1v E2 vs C: Limb loading (+exp1)

Nstart=12 Nend=12 TPS=Chronic A + B vs C Also in Table 5 (Task-Specific Training)	C: No training Duration: 3d/wk for 4wk	kinesthetic visual imagery questionnaire (No stats) gait speed (No stats) Timed Up and Go (No stats)
Proprioception Training + Motor Imagery vs Proprioception Training		
Lee et al. (2015a) RCT (5) Nstart=36 Nend=36 TPS=Chronic A + B vs A	E: Proprioception training + Motor imagery C: Proprioception training Duration: 30min/d, 5d/wk, for 8wks proprioception training & (25+5min/d) proprioception training and motor imagery	E vs C: Berg Balance Scale (+exp) Timed Up & Go Test (-) Weight Bearing Ratio (+exp) Joint Position Sense Error (+exp)
Action Observation vs Motor Imagery vs Conventional Therapy		
Kim et al. (2013) RCT (6) Nstart=30 Nend=27 TPS=Chronic A vs B vs 0 Also in Table 18 (Action Observation)	E1: Action observation training + physical training E2: Motor imagery training + physical training C: physical training Duration: 30min/d action observation and motor imagery & 1h/d, physical training, 5d/wk for 4wks	E1 vs C: Timed Up and Go (+exp1) Functional Reach test (-) Walking Ability questionnaire (-) Functional ambulation category (-) Gait speed (+exp1) Cadence (+exp1) Step length (-) Single limb support (+exp1) Double limb support (-) E2 v E1/C: Timed Up and Go (-) Functional Reach test (-) Walking Ability questionnaire (-) Functional ambulation category (-) Gait speed (-) Cadence (-) Step length (-) Single limb support (-) Double limb support (-)
Neurofeedback Facilitation with Motor Imagery vs Sham		
Mihara et al. (2024) RCT (8) Nstart=57 Nend=54 TPS=Chronic A vs 0	E: fNIRS-NFB C: Sham neurofeedback Duration: 10-20mins/d, 3ds/wk, 2wks	E vs C: TUG (+exp) Berg Balance Scale (-) Gait speed (-) FIM (-) FMA-UE (-) FMA-LE (-)
Mihara et al. (2021) RCT (8) Nstart=57 Nend=54 TPS=Chronic A + B vs B Also in Table 15 (Biofeedback)	E: Neurofeedback facilitation + motor imagery C: Sham neurofeedback + motor imagery Duration: 3 session/wk, 2wks	E vs C: Timed Up and Go (+exp) Functional Independence measure (-) Fugl-Meyer assessment Upper extremity (-) Lower extremity (-) Berg Balance scale (+exp) Gait speed (-)

Mental Practice vs Muscle Relaxation		
Oostra et al. (2015) RCT (6) Nstart=44 Nend=44 TPS=Subacute A vs B	E: Motor imagery training + standard rehabilitation program C: Muscle relaxation + Standard rehabilitation program Duration: 180min/d, 5d/wk, 6wks & 30min/d, 5d/wk, 6wks MIT or MR	E vs C: Movement Imagery Questionnaire-revised Visual (-) Kinesthetic (+exp) Walking trajectory test (imagery walking time/actual walking time) (-) 10-m walk test (+exp) Lower-extremity Fugl-Meyer assessment scale (-)
Circuit Training with Mental Practice vs Circuit Training with Education		
Aung et al. (2022) RCT (7) Nstart=40 Nend=40 TPS=Chronic A + B vs C + B	E: Motor imagery + Progressive circuit class therapy C: Health education + Structured progressive circuit class therapy Duration: 90 mins/d (25 mins of motor imagery/health education + 65 mins of structured progressive circuit class therapy), 3ds/wk, 4wks	E vs C: step test affected limb (+exp) unaffected limb (+exp) 6 minute walk test (-) TUG (+exp)
Bovonsunthonchai et al. (2020) RCT (8) Nstart=40 Nend=40 TPS=Chronic A + B vs A + C	E: Structured Progressive Circuit Training (SPCCT) + Motor Imagery (MI) C: Structured Progressive Circuit Training + Health Education (HE) Duration: 25min HE or MI + 65min SPCCT) 90min/d, 3d/wk, 4wks	E vs C: Step Length (-) Stride Length (-) Step Time affected (-) unaffected (+exp) Gait Speed (-) Cadence (-) Symmetry index step length (-) step time (-) Mximum voluntary isometric contraction Hip flexor (+exp) Hip extensor (-) knee flexor (-) knee extensor (+exp) Ankle dorsiflexor (-) Ankle plantar flexor (-)
Mental Imagery vs Mental Imagery with Auditory Stimulation		
Kim et al. (2011) RCT crossover (4) Nstart=18 Nend=15 TPS=Chronic A1 vs A2 vs B1 vs B2	E1: Visual Locomotor Imagery Training E2: Kinesthetic Locomotor Imagery Training E3: Visual Locomotor Training with Auditory Step Rhythm E4: Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm Duration: 15 min/condition, 24 hr washout	E1 vs E2: Timed Up and Go Test (-) E1 vs E3: Timed Up and Go Test (-) E1 vs E4: Timed Up and Go Test (+exp4) Muscle Activation by EMG Parameter (+exp4) E2 vs E3: Timed Up and Go Test (-) E2 vs E4: Timed Up and Go Test (-) E3 vs E4: Timed Up and Go Test (-)

Mental Imagery vs Conventional Training or Sham		
Diaz-Lopez et al. (2022) RCT (5) Nstart=49 Nend=38 TPS=Subacute A vs B	E: Recognition of laterality using implicit motor imagery + conventional rehab C: Recognition of body parts + conventional rehab Duration: Intervention: 5-10 mins/d, 3ds/wk, 4wks; conventional rehab: 40 min/d,5d/wk,4wks	E vs C: Area swing area (+exp) Long oscillation path length (-) DIFLOAD percentage of difference in weightload between lower limbs (-) Berg balance scale (+exp) Barthel Index (-) TUG (-) Functional ambulatory categories (+exp) Quality of life scale for stroke (+exp)
Yin et al. (2021) RCT (5) Nstart=39 Nend=32 TPS=Subacute A vs 0	E: Motor imagery training + conventional care C: Conventional care Duration: 20min/d, 5d/wk, 6wks MT & 180min/d, 5d/wk, 6wks conventional care	E vs C: Fugl Meyer Assessment (+exp) Functional Independence Measure (+exp) Berg Balance Scale (+exp)
Dickstein et al. (2013) RCT crossover (6) Nstart=25 Nend=23 TPS=Chronic A vs B	E: Integrated imagery practice C: Conventional care for upper extremity Duration: 15min/d, 3d/wk, 4wks	E vs C: Falls-efficacy scale - Swedish version (-) Step Activity monitor (-) 10m Walk test (+exp)
Braun et al. (2012) RCT (7) Nstart=36 Nend=34 TPS=Subacute A + B vs C	E: Mental practice + multi- professional rehabilitation C: multi-professional rehabilitation Duration: 6wks	E vs C: Motricity Index (-) Barthel Index (-) 9 Hole Peg test (-) Berg Balance scale (-) Rivermead Mobility index (-) 10m Walk Test (-)
Schuster et al. (2012) RCT (7) Nstart=41 Nend=41 TPS=Chronic A1 vs A2 vs 0	E1: Conventional rehabilitation + Embedded mental practice E2: Conventional rehabilitation + Added mental practice C: Conventional rehabilitation + listen to a sham tape Duration: 45-50min total (25-30 min PT + 20min MI/taping)/session, 6 sessions/ 2wks	E1 vs E2 vs C: Chedoke-McMaster Stroke Assessment (-) Time needed to perform the motor task (-) Barthel index (-) Berg Balance Scale (-) Computer-based Imaprax questionnaire (-) Kinesthetic and Visual Imagery Questionnaire (-) Activities-Specific Balance Confidence Scale (-) Edinburgh Handedness Inventory (-) Mini-Mental State Examination (-)
Hosseini et al. (2012) RCT (8) Nstart=30 Nend=30 TPS=Chronic A vs 0	E: Mental Practice + Conventional Treatment C: Conventional Treatment Duration: 45min/d, 3d/wk, 5wks	E vs C: Timed Up and Go Test (+exp) Berg Balance Test (+exp)
Bovend'Eerdt et al. (2010) RCT (8) Nstart=30 Nend=30	E: Motor imagery + Conventional therapy C: Sham + Conventional therapy Duration: 120min/d, 2-3d/wk, 5- 6wks	E vs C: Goal Attainment Scaling (-) Barthel index (-) Rivermead Mobility Index (-)

TPS=Subacute A vs 0		Timed UP and GO (-) Action Research Arm Test (-) Nottingham Extended ADL scale (-) Imagery Questionnaire (-)
Liu et al. (2004) RCT (7) Nstart=49 Nend=46 TPS=Acute A vs B	E: Mental imagery program C: Conventional functional training Duration: 60min/d, 5d/wk, for 3wks	E vs C: Task Performance Trained (+exp) Untrained (+exp) Color Trails Test (+exp) Fugl-Meyer Assessment Upper Extremity (-) Lower Extremity (-) Sensation (-)
Body Awareness Therapy vs Continuing Usual Daily Activities		
Lindvall et al. (2014) RCT (7) Nstart=46 Nend=43 TPS=Chronic A vs B	E: Body awareness therapy C: Continuing usual daily activities Duration: 60min/d, 1d/wk, 8wks	E vs C: Berg Balance Scale (-) Timed Up and Go Test (-) cognitive (-) 6-minute walk test (-) Timed-Stands Test (-) Activities-specific Balance Confidence Scale (-) Short Form 36 (SF36) (-)
Cognitive and Motor Dual-Task Training vs Motor Imagery		
Mishra et al. (2015) RCT (5) Nstart=15 Nend=15 TPS=Not reported A1 vs A2 vs B Also in Table 16 (Dual-Task Training)	E1: Motor dual task training + Conventional care E2: Cognitive dual task training + Conventional care E3: Motor imagery + Conventional care Duration: 15min/session, 5d/wk for 2wks	E1 v E2/E3: Berg Balance scale (-) Functional gait assessment scale (+exp1)
Cognitive Sensory Motor Training vs Conventional Therapy		
Kim et al. (2021a) RCT (6) Nstart=39 Nend=35 TPS=Chronic A vs 0 vs B	E: Cognitive Sensory Motor Training + conventional physical therapy C: Conventional physical therapy Duration: E: 30min/d CSMT + 30min/d Conventional PT, 5d/wk, 6wks C: 30min, 2sessions/d, 5d/wk, 6wks conventional physical therapy	E vs C: Lower extremity muscle strength of tibialis anterior (+exp) Medical research council (+exp) Romberg balance test Eye open surface area (+exp) Eye open average speed (+exp) Eye close surface area (+exp) Eye close average speed (+exp) Limits of stability (+exp)
Mental Practice vs Cognitive Training		
Guerra et al. (2022) RCT (6) Nstart=18 Nend=16 TPS=Acute A + B vs C + B	E: Mental Practice + physical exercise protocol C: Cognitive training + Physical exercise protocol Duration: 70min/d(30min mental practice, 40min physical activity), 3d/wk, 4wks	E vs C: TUG(-) Gait speed(-) Muscle strength(-) DASS-21(-) WHOQOL(-)

Motor Imagery with Virtual Reality vs Virtual Reality Alone		
Masood et al. (2024) RCT (8) Nstart=30 Nend=28 TPS=Not reported A + B vs B Also in Table 26 (Virtual Reality)	E: Motor imagery + VR training C: VR training + Conventional therapy Duration: 45-50min/d, 3d/wk, 6wks	E vs C: FMA-LE (+exp) BBS (+exp) WGS (+exp) TUG (+exp) 10MWT (+exp)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Zafar et al. (2024) RCT (7) Nstart=30 Nend=29 TPS=Subacute A + B vs A Primary listing: Table 16 (Dual-Task Training)	E: Dual-task training + motor imagery C: Dual-task training Duration: 28min (7 task x 4min)/d, 8wks	E vs C: Functional Reach Test (-) TUG (+exp) BBS (+exp) Movement Imagery Questionnaire-3 (+exp) internal imagery (+exp) external imagery (+exp) kinesthetic (+exp)
Suchetha et al. (2018) RCT (5) Nstart=30 Nend=28 TPS=Subacute A vs 0 Primary listing: Table 2 (Sit-to-Stand Training)	E: Modified sit-to-stand training with mental practice + conventional therapy C: Conventional Treatment Duration: 1h/d, 5d/wk, 2wks	E vs C: Berg Balance Scale (+exp) Dynamic Gait Index (+exp)
Verma et al. (2011) RCT (8) Nstart=30 Nend=30 TPS=Subacute A + B vs 0 Primary listing: Table 5 (Task-Specific Training)	E: Task-oriented circuit class training + Motor imagery C: Standard rehabilitation (Bobath) Duration: 15min/d, 7d/wk, 2wks motor imagery, 25min/d, 7d/wk, 2wks task-oriented circuit class training, 40min/d, 7d/wk, 2wks standard rehabilitation	E vs C: Functional ambulation category (+exp) Rivermead Visual gait assessment (+exp) Step length asymmetry (-) Cadence (+exp) Stride length asymmetry (-) 10-meter Walk test Maximum speed (-) Comfortable speed (+exp) 6-Minute Walk test (+exp)
Kim et al. (2011) RCT crossover (4) Nstart=18 Nend=15 TPS=Chronic A1 vs A2 vs B1 vs B2 Primary listing: Table 22 (Rhythmic Auditory Stimulation)	E1: Visual Locomotor Imagery Training E2: Kinesthetic Locomotor Imagery Training E3: Visual Locomotor Training with Auditory Step Rhythm E4: Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm Duration: 15 min/condition, 24 hr washout	E1 vs E2: Timed Up and Go Test (-) E1 vs E3: Timed Up and Go Test (-) E1 vs E4: Timed Up and Go Test (+exp4) muscle activation by EMG parameter (+exp4) E2 vs E3: Timed Up and Go Test (-) E2 vs E4: Timed Up and Go Test (-) E3 vs E4: Timed Up and Go Test (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Gait Training with Motor Imagery or Mental Practice may produce greater improvements in motor recovery than Gait Training.	2	Anwar et al. 2022; Cho et al. 2013b
1b	Task-Specific Training with Mental Practice may not have a difference in efficacy when compared to Conventional Training or No Treatment for improving motor recovery.	1	Malouin et al. 2009
1a	Neurofeedback Facilitation with Motor Imagery may not have a difference in efficacy when compared to Sham for improving motor recovery.	2	Mihara et al. 2024; Mihara et al. 2021
1b	Mental Practice may not have a difference in efficacy when compared to Muscle Relaxation for improving motor recovery.	1	Oostra et al. 2015
1a	Mental Imagery may not have a difference in efficacy when compared to Conventional Training or Sham for improving motor recovery.	3	Yin et al. 2021; Schuster et al. 2012; Liu et al. 2004
1b	Motor Imagery with Virtual Reality may produce greater improvements in motor recovery than Virtual Reality Alone.	1	Masood et al. 2024

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Task-Specific Training with Mental Practice may not have a difference in efficacy when compared to Conventional Training or No Treatment for improving biomechanical gait measures.	1	Verma et al. 2011
1b	Action Observation may not have a difference in efficacy when compared to Motor Imagery or Conventional Therapy for improving biomechanical gait measures.	1	Kim et al. 2013
1b	Circuit Training with Mental Practice may not have a difference in efficacy when compared to Circuit Training with Education for improving biomechanical gait measures.	1	Bovonsunthonchai et al. 2020
2	Mental Imagery may not have a difference in efficacy when compared to Conventional Training or Sham for improving biomechanical gait measures.	1	Diaz-Lopez et al. 2022
1b	Task-oriented circuit class training with Motor imagery may not have a difference in efficacy when compared to rehabilitation (Bobath) for improving biomechanical gait measures.	1	Verma et al. 2011

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Task-Specific Training with Mental Practice may produce greater improvements in biomechanical balance measures than Conventional Training or No Treatment.	1	Malouin et al. 2009
2	Proprioception Training with Motor Imagery may produce greater improvements in biomechanical balance measures than Proprioception Training.	1	Lee et al. 2015a

1b	Cognitive Sensory Motor Training may produce greater improvements in biomechanical balance measures than Conventional Therapy.	1	Kim et al. 2021a

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Task-Specific Training with Mental Practice may produce greater improvements in muscle strength than Task-Specific Training.	1	Kumar et al. 2016
1b	Circuit Training with Mental Practice may not have a difference in efficacy when compared to Circuit Training with Education for improving muscle strength.	1	Bovonsunthonchai et al. 2020
1b	Mental Imagery may not have a difference in efficacy when compared to Conventional Training or Sham for improving muscle strength.	1	Braun et al. 2012
1b	Cognitive Sensory Motor Training may produce greater improvements in muscle strength than Conventional Therapy.	1	Kim et al. 2021a
1b	Mental Practice may not have a difference in efficacy when compared to Cognitive Training for improving muscle strength.	1	Guerra et al. 2022

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Visual Locomotor Imagery Training may result in lesser improvements in neurophysiological measures when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.	1	Kim et al. 2011

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Proprioception Training with Motor Imagery may produce greater improvements in sensory and proprioceptive function than Proprioception Training.	1	Lee et al. 2015a

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Neurofeedback Facilitation with Motor Imagery may not have a difference in efficacy when compared to Sham for improving activities of daily living.	2	Mihara et al. 2024; Mihara et al. 2021
1b	Mental Practice may not have a difference in efficacy when compared to Muscle Relaxation for improving activities of daily living.	1	Oostra et al. 2015
1a	Mental Imagery may not have a difference in efficacy when compared to Conventional Training or Sham for improving activities of daily living.	6	Diaz-Lopez et al. 2022; Yin et al. 2021; Braun et al. 2012; Schuster et al. 2012; Bovend'Eerdt et al. 2010; Liu et al. 2004

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Gait Training with Motor Imagery or Mental Practice may produce greater improvements in gait speed than Gait Training.	3	Anwar et al. 2022; Sawant 2020; Cho et al. 2013b

1b	Task-Specific Training with Mental Practice may produce greater improvements in gait speed than Task-Specific Training.	1	Kumar et al. 2016
1a	Task-Specific Training with Mental Practice may not have a difference in efficacy when compared to Conventional Training or No Treatment for improving gait speed.	2	Verma et al. 2011; Malouin et al. 2009
1b	There is conflicting evidence about the effect of Action Observation when compared to Motor Imagery or Conventional Therapy for improving gait speed.	1	Kim et al. 2013
1a	Neurofeedback Facilitation with Motor Imagery may not have a difference in efficacy when compared to Sham for improving gait speed.	2	Mihara et al. 2024; Mihara et al. 2021
1b	Mental Practice may produce greater improvements in gait speed than Muscle Relaxation.	1	Oostra et al. 2015
1b	Circuit Training with Mental Practice may not have a difference in efficacy when compared to Circuit Training with Education for improving gait speed.	1	Bovonsunthonchai et al. 2020
1a	There is conflicting evidence about the effect of Mental Imagery when compared to Conventional Training or Sham for improving gait speed.	2	Dickstein et al. 2013; Braun et al. 2012
1b	Cognitive Sensory Motor Training may produce greater improvements in gait speed than Conventional Therapy.	1	Kim et al. 2021a
1b	Mental Practice may not have a difference in efficacy when compared to Cognitive Training for improving gait speed.	1	Guerra et al. 2022
1b	Motor Imagery with Virtual Reality may produce greater improvements in gait speed than Virtual Reality Alone.	1	Masood et al. 2024
1b	There is conflicting evidence about the effect of Task-oriented circuit class training with Motor imagery when compared to rehabilitation (Bobath) for improving gait speed.	1	Verma et al. 2011

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Task-Specific Training with Mental Practice may produce greater improvements in gait endurance than Conventional Training or No Treatment.	1	Verma et al. 2011
1b	Circuit Training with Mental Practice may not have a difference in efficacy when compared to Circuit Training with Education for improving gait endurance.	1	Aung et al. 2022
1b	Body Awareness Therapy may not have a difference in efficacy when compared to Continuing Usual Daily Activities for improving gait endurance.	1	Lindvall et al. 2014
1b	Task-oriented circuit class training with Motor imagery may produce greater improvements in gait endurance than rehabilitation (Bobath).	1	Verma et al. 2011

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Gait Training with Motor Imagery or Mental Practice may produce greater improvements in functional mobility than Gait Training.	2	Sawant 2020; Cho et al. 2013b
1a	Task-Specific Training with Mental Practice may produce greater improvements in functional mobility than Conventional Training or No Treatment.	2	Verma et al. 2011; Malouin et al. 2009

2	Proprioception Training with Motor Imagery may not have a difference in efficacy when compared to Proprioception Training for improving functional mobility.	1	Lee et al. 2015a
1b	Action Observation may not have a difference in efficacy when compared to Motor Imagery or Conventional Therapy for improving functional mobility.	1	Kim et al. 2013
1a	Neurofeedback Facilitation with Motor Imagery may produce greater improvements in functional mobility than Sham.	2	Mihara et al. 2024; Mihara et al. 2021
1b	Circuit Training with Mental Practice may produce greater improvements in functional mobility than Circuit Training with Education.	1	Aung et al. 2022
2	Visual Locomotor Imagery Training may not have a difference in efficacy when compared to Kinesthetic Locomotor Imagery Training for improving functional mobility.	1	Kim et al. 2011
2	Visual Locomotor Imagery Training may not have a difference in efficacy when compared to Visual Locomotor Training with Auditory Step Rhythm for improving functional mobility.	1	Kim et al. 2011

Key Points

- Gait Training with Motor Imagery or Mental Practice may be beneficial for improving motor recovery, gait speed, functional mobility, and balance after stroke when compared to Gait Training.
- Task-Specific Training with Mental Practice may be beneficial for improving muscle strength and gait speed after stroke when compared to Task-Specific Training.
- Task-Specific Training with Mental Practice may be beneficial for improving biomechanical balance measures, gait endurance, and functional mobility, but not motor recovery, biomechanical gait measures, and gait speed, after stroke when compared to Conventional Training or No Treatment.
- Proprioception Training with Motor Imagery may be beneficial for improving biomechanical balance measures, sensory and proprioceptive function, and balance, but not functional mobility, after stroke when compared to Proprioception Training.
- Action Observation may not be beneficial for improving biomechanical gait measures, functional mobility, and balance after stroke when compared to Motor Imagery or Conventional Therapy; the literature is mixed regarding gait speed.
- Neurofeedback Facilitation with Motor Imagery may be beneficial for improving functional mobility, but not motor recovery, activities of daily living, and gait speed, after stroke when compared to Sham; the literature is mixed regarding balance.
- Mental Practice may be beneficial for improving gait speed, but not motor recovery and activities of daily living, after stroke when compared to Muscle Relaxation.
- Circuit Training with Mental Practice may be beneficial for improving functional mobility, but not biomechanical gait measures, muscle strength, gait speed, and gait endurance, after stroke when compared to Circuit Training with Education.
- Visual Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training.
- Visual Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Visual Locomotor Training with Auditory Step Rhythm.
- Visual Locomotor Imagery Training may result in lesser improvements in neurophysiological measures and functional mobility when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.
- Kinesthetic Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Visual Locomotor Training with Auditory Step Rhythm.

- Kinesthetic Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.
- Visual Locomotor Training with Auditory Step Rhythm may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.
- Mental Imagery may be beneficial for improving balance and quality of life, but not motor recovery, biomechanical gait measures, muscle strength, activities of daily living, functional mobility, and falls and fear of falling, after stroke when compared to Conventional Training or Sham; the literature is mixed regarding gait speed.
- Body Awareness Therapy may not be beneficial for improving gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Continuing Usual Daily Activities.
- Motor dual task training with Conventional care may be beneficial for improving functional mobility, but not balance, after stroke when compared to Cognitive dual task training with Conventional care or Motor imagery and Conventional care.
- Cognitive Sensory Motor Training may be beneficial for improving biomechanical balance measures, muscle strength, gait speed, and balance after stroke when compared to Conventional Therapy.
- Mental Practice may not be beneficial for improving muscle strength, gait speed, functional mobility, and quality of life after stroke when compared to Cognitive Training.
- Motor Imagery with Virtual Reality may be beneficial for improving motor recovery, gait speed, functional mobility, and balance after stroke when compared to Virtual Reality Alone.
- Dual-task training with motor imagery may be beneficial for improving functional mobility and balance after stroke when compared to Dual-task training.
- Modified sit-to-stand training with mental practice with conventional therapy may be beneficial for improving functional mobility and balance after stroke when compared to Conventional Treatment.
- Task-oriented circuit class training with Motor imagery may be beneficial for improving gait endurance and functional mobility, but not biomechanical gait measures, after stroke when compared to rehabilitation (Bobath); the literature is mixed regarding gait speed.

Summary of Key Points: Mental Practice

Intervention	Control(s)	Function domain(s)	Effect
Gait Training with Motor Imagery or Mental Practice	Gait Training	Motor recovery, gait speed, functional mobility, balance	+
Task-Specific Training with Mental Practice	Task-Specific Training	Muscle strength, gait speed	+
Task-Specific Training with Mental Practice	Conventional Training or No Treatment	Biomechanical balance measures, gait endurance, functional mobility	+
Task-Specific Training with Mental Practice	Conventional Training or No Treatment	Motor recovery, biomechanical gait measures, gait speed	–
Proprioception Training with Motor Imagery	Proprioception Training	Biomechanical balance measures, sensory and proprioceptive function, balance	+
Proprioception Training with Motor Imagery	Proprioception Training	Functional mobility	–
Action Observation	Motor Imagery vs Conventional Therapy	Biomechanical gait measures, functional mobility, balance	–
Action Observation	Motor Imagery vs Conventional Therapy	Gait speed	=
Neurofeedback Facilitation with Motor Imagery	Sham	Functional mobility	+

Neurofeedback Facilitation with Motor Imagery	Sham	Motor recovery, activities of daily living, gait speed	–
Neurofeedback Facilitation with Motor Imagery	Sham	Balance	=
Mental Practice	Muscle Relaxation	Gait speed	+
Mental Practice	Muscle Relaxation	Motor recovery, activities of daily living	–
Circuit Training with Mental Practice	Circuit Training with Education	Functional mobility	+
Circuit Training with Mental Practice	Circuit Training with Education	Biomechanical gait measures, muscle strength, gait speed, gait endurance	–
Visual Locomotor Imagery Training	Kinesthetic Locomotor Imagery Training	Functional mobility	–
Visual Locomotor Imagery Training	Visual Locomotor Training with Auditory Step Rhythm	Functional mobility	–
Visual Locomotor Imagery Training	Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm	Neurophysiological measures, functional mobility	–
Kinesthetic Locomotor Imagery Training	Visual Locomotor Training with Auditory Step Rhythm	Functional mobility	–
Kinesthetic Locomotor Imagery Training	Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm	Functional mobility	–
Visual Locomotor Training with Auditory Step Rhythm	Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm	Functional mobility	–
Mental Imagery	Conventional Training or Sham	Balance, quality of life	+
Mental Imagery	Conventional Training or Sham	Motor recovery, biomechanical gait measures, muscle strength, activities of daily living, functional mobility, falls and fear of falling	–
Mental Imagery	Conventional Training or Sham	Gait speed	=
Body Awareness Therapy	Continuing Usual Daily Activities	Gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Motor dual task training with Conventional care	Cognitive dual task training with Conventional care or Motor imagery and Conventional care	Functional mobility	+
Motor dual task training with Conventional care	Cognitive dual task training with Conventional care or Motor imagery and Conventional care	Balance	–
Cognitive Sensory Motor Training	Conventional Therapy	Biomechanical balance measures, muscle strength, gait speed, balance	+
Mental Practice	Cognitive Training	Muscle strength, gait speed, functional mobility, quality of life	–
Motor Imagery with Virtual Reality	Virtual Reality Alone	Motor recovery, gait speed, functional mobility, balance	+
Dual-task training with motor imagery	Dual-task training	Functional mobility, balance	+

Modified sit-to-stand training with mental practice with conventional therapy	Conventional Treatment	Functional mobility, balance	+
Task-oriented circuit class training with Motor imagery	rehabilitation (Bobath)	Gait endurance, functional mobility	+
Task-oriented circuit class training with Motor imagery	rehabilitation (Bobath)	Biomechanical gait measures	−
Task-oriented circuit class training with Motor imagery	rehabilitation (Bobath)	Gait speed	=

Action Observation

Adopted from: https://www.youtube.com/watch?v=QE3CUhmKi7U

Action observation is a form of therapy whereby an individual observes another individual performing a motor task, either on a video or a real demonstration, and then may attempt to perform the same task themselves. For example, the patient may be instructed to watch a video showing an adult stretching out his hand to pick up a cup, bringing the cup to his mouth, and then returning the cup to its initial position - the act of drinking. After observing the video sequence for a time, the participants may or may not be asked to perform the same action (Borges et al., 2018). The therapy is considered a multisensory approach designed to increase cortical excitability in the primary motor cortex by activating central representations of actions through the mirror neuron system (Kim & Kim, 2015). Although action observation has been evaluated mainly in healthy volunteers, a few studies have evaluated its benefit in motor relearning following stroke.

A total of fourteen RCTs were found that evaluated action observation for lower extremity motor rehabilitation. Two RCTs compared Backward Walking Action Observation with Sham or Conventional therapy (Moon et al. 2022; Moon & Bae 2019). Two RCTs compared Action Observation Physical Training with Sham Action Observation Training (Shamsi et al. 2022; Kim et al. 2018b). One RCT compared Functional Action Observation with General Action Observation (Oh et al. 2019). Five RCTs compared Action Observation Training with Gait Training with Gait Training (Park et al. 2017b; Park et al. 2015c; Park et al. 2014b; Kim et al. 2013; Kim & Kim 2012a). One RCT compared Action Observation with Treadmill Training with Treadmill Training (Bang et al. 2013). Two RCTs compared Action Observation with FES and Gait Training with Gait Training and FES (Bae et al. 2017; Park & Kang 2013a). One RCT evaluated Action Observation with Rhythmic Auditory Stimulation (Cho et al. 2020a).

In addition, three RCTs in which action observation formed part of a combined or comparative intervention are cross-referenced at the end of Table 18; their primary listings appear in other tables.

The methodological details and results of all fourteen RCTs are presented in Table 18.

Table 18. RCTs Evaluating Action Observation for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)
Backward Walking Action Observation vs Sham or Conventional therapy		
Moon et al. (2022) RCT (6) Nstart=29 Nend=24 TPS=Chronic A vs B Also in Table 7 (Non-Technological Overground Walking and Gait Training)	E: Backward walking observational training & Conventional therapy C: Landscape observational training (sham) & Conventional therapy Duration: 30min/d, 3d/wk, for 4wks observational training & 30min/d, 5d/wk, for 4wks conventional therapy	E vs C: Gait velocity (+exp) Step length (+exp) Stride length (+exp) 5 timed sit-to stand(+exp) Activities-specific balance confidence scale(+exp) Affected side Weight distribution (+exp) Center of pressure displacement (+exp) Velocity (+exp) Length (+exp)
Moon & Bae (2019) RCT (6) Nstart=17 Nend=14 TPS=Chronic A vs B + A Also in Table 7 (Non-Technological Overground Walking and Gait Training)	E: Action observation of backward walking C: Landscape video + Backward walking training Duration: 30min/d, 5d/wk for 4wks - Conventional therapy, 10min/d - Action observation or Landscape video, 20min/d - Backwards walking training	E vs C: Dynamic Gait Index (+exp) 10-Metre Walking Test (+exp) Timed Up and Go Test (+exp)
Action Observation Physical Training vs Sham Action Observation Training		
Shamsi et al. (2022) RCT (8) Nstart=14 Nend=14 TPS=Chronic A vs B	E: Observation training depicting exercises C: Observation nature pictures (sham) Duration: 40min/d, 3d/wk, 4wks conventional PT & 12min/d, 3d/wk, 4wks action observation training/sham	E vs C: Stride length (Affected/Unaffected) (-) Step length (Affected/Unaffected) (-) Gait Velocity (Affected/Unaffected) (-) Stance phase Affected (-) Unaffected (+exp) Peaks of vertical ground reaction force (Affected/Unaffected) (-) Gait asymmetry index (-)
Kim et al. (2018b) RCT crossover (5) Nstart=24 Nend=21 TPS=Chronic A vs B	E: Action observation physical training C: Landscape imagery observation physical training (Sham) Duration: 30min/d, 3d/wk, for 6wks - no washout	E vs C: Limit of Stability (+exp) Weight Distribution Index (-) Timed-up-and go (-) Dynamic Gait Index (-)
Functional Action Observation vs General Action Observation		
Oh et al. (2019) RCT (4) Nstart=40 Nend=35 TPS=Subacute A1 vs A2	E: Functional Action Observation C: General Action Observation Duration: 30min/d, 5d/wk, for 4wks	E vs C: Velocity (+exp) Step length (+exp) Stride length (+exp) Cadence (+exp) Functional Gait Assessment (+exp)

Action Observation Training with Gait Training vs Gait Training		
Park et al. (2017b) RCT (6) Nstart=26 Nend=25 TPS=Chronic A + B vs C + B Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)	E: Action observation of community ambulation + Functional training based on neurodevelopmental techniques C: Landscape observation + Functional training based on neurodevelopmental techniques Duration: 30min/d, 5sessions/d for 4wks Functional training & 30min/d, 3d/wk for 4wks Action or landscape observation	E vs C: 10-meter Walk Test (+exp) Community Walk Test (+exp) Activity-specific Balance Confidence Scale (+exp) Gait Cycle Time (-) Stride Length (+exp) Single Support (+exp) Double Support (-) Gait Velocity (+exp) Symmetry Index (-) Swing (-) Stance (-) Step (-)
Park et al. (2015c) RCT (4) Nstart=40 Nend=40 TPS=Chronic A vs B	E: Gait training + Action observation + General physical therapy C: Gait training + Nature video + General physical therapy Duration: 70min/d, 5d/wk for 8wks	E vs C: 10-Metre Walk Test (+exp) Timed Up & Go Test (+exp) Limit of stability (+exp) Sway speed (+exp) Sway area (-)
Park et al. (2014b) RCT (7) Nstart=24 Nend=21 TPS=Chronic A vs 0	E: Action observation + Gait training C: Sham + Gait training Duration: 30min/d, 3d/wk, 4wks	E vs C: 10m Walk Test (+exp) Figure-of-8 Walk Test (+exp) Dynamic Gait Index (+exp) Gait Symmetry Scores (-)
Kim et al. (2013) RCT (6) Nstart=30 Nend=27 TPS=Chronic A vs B vs 0 Also in Table 17 (Mental Practice)	E1: Action observation training + physical training E2: Motor imagery training + physical training C: physical training Duration: 30min/d action observation and motor imagery & 1h/d, physical training, 5d/wk for 4wks	E1 vs C: Timed Up and Go (+exp1) Functional Reach test (-) Walking Ability questionnaire (-) Functional ambulation category (-) Gait speed (+exp1) Cadence (+exp1) step length (-) Single limb support (+exp1) Double limb support (-) E2 vs E1/C: Timed Up and Go (-) Functional Reach test (-) Walking Ability questionnaire (-) Functional ambulation category (-) Gait speed (-) Cadence (-) step length (-) Single limb support (-) Double limb support (-)
Kim & Kim (2012a) RCT (5) Nstart=30 Nend=30 TPS=Subacute	E: Physical therapy + Action observation C: Sham + Physical therapy Duration: 10min action observation & 30min physical therapy	E vs C: Gait speed (+exp) Step length (+exp) Stride length (+exp) Single support time (+exp)

A vs 0		Double support time (+exp) Cadence (+exp)
Action Observation with Treadmill Training vs Treadmill Training		
Bang et al. (2013) RCT (7) Nstart=30 Nend=30 TPS=Chronic A + B vs B Also in Table 9 (Treadmill Training)	E: Action observational training + Treadmill training C: Sham action observational training + Treadmill training Duration: 40min/d, 5d/wk for 4wks	E vs C: Timed Up and Go test (+exp) 10m Walk test (+exp) 6min Walk test (+exp) Max Knee Angle in Swing Phase (+exp)
Action Observation with FES and Gait Training vs Gait Training and FES		
Bae et al. (2017) RCT (6) Nstart=18 Nend=18 TPS=Chronic A + B vs C Also in Table 28 (Functional Electrical Stimulation); Table 29 (Neuromuscular Electrical Stimulation (NMES))	E: Dual-afferent sensory input (EMG-triggered FES + Action Observation) C: Functional electric stimulation (FES) Duration: 20min/d, 5d/wk, for 4wks	E vs C: Movement-related Cortical Potential Bereitschafts Potential (-) Negative Slope (-) Motor Potential (+exp) Muscle Activity Tibialis Anterior (-) Medial Gastrocnemius (-) H-reflex (-) Balance Surface Area Ellipse (-) Surface Area Length (-) Limit Of Stability (+exp)
Park & Kang (2013a) RCT (5) Nstart=20 Nend=20 TPS=Chronic A + B vs A Also in Table 28 (Functional Electrical Stimulation)	E: Gait training + FES + Action observation C: Gait training + FES Duration: 15min/d, 5d/wk for 6wks	E vs C: Weight distribution Right Left (+exp) Anterior Posterior (-) Stability index (+exp) Gait speed (+exp)
Action Observation with Rhythmic Auditory Stimulation		
Cho et al. (2020a) RCT (6) Nstart=30 Nend=30 TPS=Chronic A + B vs A Also in Table 22 (Rhythmic Auditory Stimulation)	E: Action observation training + Rhythmic auditory stimulation + PT C: Action observation + PT Duration: 15min, 2sessions/d, 3d/wk, for 8wks action observation & 5d/wk, for 8wks PT	E vs C: Postural stability test Overall balance index (+exp) Anteroposterior balance index (+exp) Mediolateral balance index (+exp) Fall Risk (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

2	Action Observation with functional electrical stimulation and Gait Training may produce greater improvements in gait speed than Gait Training and functional electrical stimulation.	1	Park & Kang 2013a

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Action Observation with Treadmill Training may produce greater improvements in gait endurance than Treadmill Training.	1	Bang et al. 2013

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Backward Walking Action Observation may produce greater improvements in functional mobility than Sham or Conventional therapy.	2	Moon et al. 2022; Moon & Bae 2019
2	Action Observation Physical Training may not have a difference in efficacy when compared to Sham Action Observation Training for improving functional mobility.	1	Kim et al. 2018b
2	Functional Action Observation may produce greater improvements in functional mobility than General Action Observation.	1	Oh et al. 2019
1a	Action Observation Training with Gait Training may not have a difference in efficacy when compared to Gait Training for improving functional mobility.	4	Park et al. 2017b; Park et al. 2015c; Park et al. 2014b; Kim et al. 2013
1b	Action Observation with Treadmill Training may produce greater improvements in functional mobility than Treadmill Training.	1	Bang et al. 2013

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Action Observation Training with Gait Training may not have a difference in efficacy when compared to Gait Training for improving balance.	1	Kim et al. 2013
1b	Action Observation with functional electrical stimulation and Gait Training may not have a difference in efficacy when compared to Gait Training and functional electrical stimulation for improving balance.	1	Bae et al. 2017

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Backward Walking Action Observation may produce greater improvements in falls and fear of falling than Sham or Conventional therapy.	1	Moon et al. 2022
1b	Action Observation Training with Gait Training may produce greater improvements in falls and fear of falling than Gait Training.	1	Park et al. 2017b
1b	Action observation training with Rhythmic auditory stimulation and physical therapy may produce greater improvements in falls and fear of falling than Action observation with physical therapy.	1	Cho et al. 2020a

Key Points

- Backward Walking Action Observation may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility, and falls and fear of falling after stroke when compared to Sham or Conventional therapy.
- Action Observation Physical Training may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and functional mobility after stroke when compared to Sham Action Observation Training.
- Functional Action Observation may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to General Action Observation.
- Action Observation Training with Gait Training may be beneficial for improving biomechanical balance measures, gait speed, and falls and fear of falling, but not biomechanical gait measures, functional mobility, and balance, after stroke when compared to Gait Training.
- Action Observation with Treadmill Training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill Training.
- Action Observation with functional electrical stimulation and Gait Training may be beneficial for improving biomechanical balance measures and gait speed, but not neurophysiological measures and balance, after stroke when compared to Gait Training and functional electrical stimulation.
- Action observation training with Rhythmic auditory stimulation and physical therapy may be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Action observation with physical therapy.

Summary of Key Points: Action Observation

Intervention	Control(s)	Function domain(s)	Effect
Backward Walking Action Observation	Sham or Conventional therapy	Biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility, falls and fear of falling	+
Action Observation Physical Training	Sham Action Observation Training	Biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility	−
Functional Action Observation	General Action Observation	Biomechanical gait measures, gait speed, functional mobility	+
Action Observation Training with Gait Training	Gait Training	Biomechanical balance measures, gait speed, falls and fear of falling	+
Action Observation Training with Gait Training	Gait Training	Biomechanical gait measures, functional mobility, balance	−

Mirror Therapy

Adopted from: https://en.wikipedia.org/wiki/Mirror_box

In mirror therapy, a mirror is placed beside the unaffected limb, blocking view of the affected limb and creating an illusion of two limbs as if they are both functioning normally. Mirror therapy functions through a process known as mirror visual feedback wherein the movement of one limb is perceived as movement from the other limb (Deconinck et al., 2015). In the brain, mirror therapy is thought to induce neuroplastic changes that promote recovery by increasing excitability of the ipsilateral motor cortex which projects to the paretic limb (Deconinck et al. 2015). Ramachandran et al. (1995) first used this method to understand the effect of vision on phantom sensation and pain in arm amputees. Only recently has it been explored as method for lower limb rehabilitation in stroke survivors (Li et al., 2018).

A total of 26 RCTs were found that evaluated mirror therapy for lower extremity motor rehabilitation. Thirteen RCTs compared Mirror Therapy with Conventional Therapy or Sham Therapy (Cui et al. 2022; Armat et al. 2022; Verma et al. 2021; Ikizler May et al. 2020; Arya et al. 2019; Simpson et al. 2019; Bhoraniya et al. 2018; Wang et al. 2017; Kim et al. 2016b; Ji & Kim 2015; Salem et al. 2015; Mohan et al. 2013; Sütbeyaz et al. 2007). One RCT compared Treadmill Training Combined with Mirror Therapy with Treadmill Training (Broderick et al. 2019). Two RCTs compared Mirror Therapy with Task Oriented Training with Task Oriented Training (Cha et al. 2016; Choi et al. 2015c). Two RCTs compared Mirror Therapy with Stimulation with Mirror Therapy or Task Oriented Training (Lee et al. 2015c; Lin et al. 2014a). Two RCTs compared Mirror Therapy combined with NMES with Mirror Therapy with Sham NMES or Conventional Therapy (Xu et al. 2017; Lee et al. 2016). Two RCTs compared Mirror Therapy combined with FES with Conventional Therapy (Li et al. 2024a; Salhab et al. 2016). One RCT compared Mirror Therapy with rTMS with Mirror Therapy with Sham Stimulation (Cha & Kim 2015). One RCT compared Mirror Therapy with Virtual Reality with Conventional therapy (Miclaus et al. 2021). One RCT compared Mirror Therapy with Verbal Feedback with Mirror Therapy Alone (Chaudhary et al. 2022).

In addition, six RCTs in which mirror therapy formed part of a combined or comparative intervention are cross-referenced at the end of Table 19; their primary listings appear in other tables.

The methodological details and results of all 26 RCTs are presented in Table 19.

Table 19. RCTs Evaluating Mirror Therapy for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Mirror Therapy vs Conventional Therapy or Sham Therapy		
Cui et al. (2022) RCT (4) Nstart=40 Nend=32 TPS=Acute A vs 0	E: Mirror Therapy (MT) + conventional rehabilitation C: Conventional rehabilitation Duration: 30min/d, 5d/wk, for 3wks	E vs C: Fugl-Meyer Assessment-Lower Extremity (+exp) Berg Balance Scale (+exp) Modified Rivermead mobility index (+exp) Modified Barthel Index (+exp) Functional connectivity (+exp) Regional homogeniety (+exp) Fractional amplitude of low-frequency fluctuations (+exp)
Armat et al. (2022) RCT (6) Nstart=40 Nend=38 TPS=Not reported A1 vs A2	E: Balance and Mirror therapy C: Balance exercise + sham mirror therapy Duration: 30min/d, 5d/wk, 4wks	E vs C: BBS(+exp)
Verma et al. (2021) RCT (5) Nstart=64 Nend=56 TPS=Chronic A vs B	E: Mirror therapy + conventional rehabilitation C: Comprehensive rehabilitation + sham therapy Duration: 30min/d, 6d/wk, for 6wks	E vs C: Brunnstrom stages (no stat) Modified Ashworth Scale (no stat) Functional Ambulation Category (+exp) Berg Balance Scale (+exp)
Ikizler May et al. (2020) RCT (6) Nstart=42 Nend=42 TPS=Subacute A vs 0	E: Mirror Therapy (MT) + Conventional rehabilitation (CR) C: Conventional Rehabilitation (CT) Duration: 60-120min/d conventional care & 30min/d - mirror therapy, 5d/wk, for 4wks	E vs C: Brunnstrom (+exp) Functional Independence Measure (+exp) Motor (+exp) Berg Balance Scale (+exp) Motricity Index (+exp) 6-minute walking test (+exp) Functional Ambulation Category (+exp) Modified Ashworth Scale (-)
Arya et al. (2019) RCT (8) Nstart=36 Nend=36 TPS=Chronic A vs 0	E: Activity-based Mirror Therapy + Conventional Therapy C: Conventional Therapy Duration: 60min (30min Mirror therapy + 30min conventional /60 min conventional therapy), 30 sessions, 3-4d/wk, for 12wks	E vs C: Brunnstrom recovery stages-LE (+exp) Fugl-Meyer assessment-LE (+exp) Rivermead visual gait assessment (+exp) 10-metre walk test comfortable speed (-) Maximum speed (-)
Simpson et al. (2019) RCT (7)	E: Home-based isometric unilateral strength training + mirror therapy	E vs C:

Nstart=35 Nend=31 TPS=Chronic A + B vs A Also in Table 21 (Strength and Resistance Training); Table 24 (Home-Based and Caregiver-Mediated Exercise Programs)	C: Home-based isometric unilateral strength training Duration: 20min/d, 3d/wk, for 4wks	Trained ankle maximum voluntary contraction (-) Untrained ankle maximum voluntary contraction (-) 10-Metre Walk Test (-) Timed Up & Go Test (-) Modified Ashworth Scale (-) London Handicap Scale (-)
Bhoraniya et al. (2018) RCT (4) Nstart=26 Nend=26 TPS=Chronic A vs 0	E: Mirror therapy + Conventional Therapy C: Conventional therapy Duration: 45min/d, 5d/wk, for 4wks	E vs C: Step length Paretic side (+exp) Non-paretic Side (+exp) Stride length Paretic side (+exp) Non-paretic Side (+exp) Cadence (+exp) Velocity (+exp)
Wang et al. (2017) RCT (4) Nstart=36 Nend=36 TPS=Acute A vs 0	E: Mirror therapy C: Conventional therapy Duration: 40min/d, 5d/wk for 6wks	E vs C: Brunnstrom Staging Score (+exp) Berg Balance Scale (+exp) Functional Ambulation Category (+exp) Functional Independence Measure (+exp)
Kim et al. (2016b) RCT (7) Nstart=34 Nend=33 TPS=Subacute A vs 0	E: Mirror therapy + Conventional rehabilitation C: Sham mirror therapy + Conventional rehabilitation Duration: 30 min/d, 5d/wk, for 4wks MT/Sham MT + 30 min/d, 5d/wk, for 4wks conventional rehabilitation	E vs C: Balance Index Overall stability index (+exp) Anterior and posterior index (-) Medial and lateral stability index (+exp)
Ji & Kim (2015) RCT (7) Nstart=34 Nend=31 TPS=Subacute A vs 0	E: Mirror therapy + Conventional therapy C: Sham mirror therapy + Conventional therapy Duration: 15min/d, 5d/wk, for 4wks mirror/sham therapy & 30min/d, 5d/wk, for 4wks conventional therapy	E vs C: Single stance (+exp) Step length (+exp) Stride length (+exp) Velocity (-) Stance phase (-) Swing phase (-) Step width (-) Cadence (-)
Salem et al. (2015) RCT (4) Nstart=30 Nend=30 TPS=Chronic A vs 0	E: Mirror therapy + Conventional therapy C: Conventional therapy + Sham mirror therapy Duration: 2-5h/d, 5d/wk for 4wks Conventional therapy & 30min/d, 5d/wk for 4wks Mirror/sham therapy	E vs C: Passive ankle dorsiflexion range of motion (+exp) Modified Ashworth scale (-) Brunnstrom stages for the lower extremity (+exp) 10-Metre Walk Test (+exp)
Mohan et al. (2013) RCT (7) Nstart=22 Nend=22 TPS=Acute A vs 0	E: Mirror therapy + conventional therapy C: Sham mirror therapy + conventional therapy Duration: 60min/d, 6d/wk, 2wks conventional therapy 30min/d, 6d/wk, 2wks mirror therapy	E vs C: Fugl-Meyer assessment of lower extremity (-) Brunel Balance assessment (-) Functional ambulation categories (+exp)
Sütbeyaz et al. (2007)	E: Mirror therapy + conventional therapy	E vs C:

RCT (7) Nstart=40 Nend=40 TPS=Subacute A vs 0	C: Sham mirror therapy + conventional therapy Duration: 30min/d, 5d/wk, for 4wks mirror/placebo therapy & 120-300min/d, 5d/wk, for 4wks conventional therapy	Brunnstrom stages of motor recovery (No stats) Modified Ashworth Scale (No stats) Functional Ambulation Categories (No stats) Functional Independence Measure (motor) (No stats)
Treadmill Training Combined with Mirror Therapy vs Treadmill Training		
Broderick et al. (2019) RCT (6) Nstart=30 Nend=23 TPS=Chronic A + B vs A Also in Table 9 (Treadmill Training)	E: Treadmill Training + Mirror Therapy C: Treadmill Training + Sham Duration: 30min, 3d/wk, for 4wks	E vs C: 10-Metre Walk Test (-) 6-Minute Walk Test (-) Modified Ashworth Scale Hip flexion (-) Hip extension (-) Hip abduction (-) Hip adduction (-) Knee flexion (-) Knee extension (-) Ankle dorsiflexion (+exp) Ankle plantarflexion (+exp) Fugl-Meyer Assessment (-)
Mirror Therapy with Task Oriented Training vs Task Oriented Training		
Cha et al. (2016) RCT (6) Nstart=25 Nend=20 TPS=Chronic A + B vs C Also in Table 5 (Task-Specific Training)	E: Task-oriented training + mirror therapy C: Task oriented training Duration: 30min/d, 2sessions/d, 5d/wk for 4wks	E vs C: Berg Balance scale (+exp) Timed Up-and-Go test (+exp) Balance index (+exp) Dynamic limit of stability (+exp)
Choi et al. (2015c) RCT (4) Nstart=26 Nend=24 TPS=Chronic A + B vs A Also in Table 15 (Biofeedback)	E: Stepper Exercise + Visual Feedback (with mirror) C : Stepper Exercise Duration: 30min/d, 3d/wk, 6wks	E vs C: Muscle Strength Hip joint extensor muscle (+exp) Knee joint extensor muscle (-) 10-Meter Walking Test (+exp) 11 Stair Climbing Test (-)
Mirror Therapy with Stimulation vs Mirror Therapy or Task Oriented Training		
Lee et al. (2015c) RCT (7) Nstart=48 Nend=47 TPS=Chronic A1 vs A + B vs A2	E1: Mirror therapy E2: Mirror therapy + Mesh glove (afferent stimulation) C: Mirror therapy + Sham mesh glove Duration: 90min/d, 5d/wk, for 4wks	E1 vs E2: ED muscle tone (+exp2) FCR muscle tone (-) muscle stiffness (-) box and block test (+exp2) FIM motor (+exp2) Fugl-Meyer Assessment (-) revised Nottingham Sensory Assessment (-) 10-meter walk test (-) E2 vs C: ED muscle tone (-) FCR muscle tone (+con) ED muscle stiffness (-)

		FCR muscle stiffness (+exp2) box and block test (-) FIM motor (-) Fugl-Meyer Assessment (-) revised Nottingham Sensory Assessment (-) 10-meter walk test (-) E1 vs C: ED muscle tone (-) FCR muscle tone (-) muscle stiffness (-) box and block test (+con) FIM motor (+con Fugl-Meyer Assessment (-) revised Nottingham Sensory Assessment (-) 10-meter walk test (-)
Lin et al. (2014a) RCT (7) Nstart=43 Nend=42 TPS=Chronic A + B vs B vs C	E1: Mesh glove providing afferent sensory stimulation + Mirror Therapy + Conventional care E2: Mirror Therapy + Conventional care C: Task-oriented training + Conventional care Duration: 1.5h/d, 5d/wk, for 4wks	E1 vs C: Fugl-Meyer assessment-upper extremity Proximal (-) Distal (-) Total (+exp1) Muscle tone using Myoton Biceps (-) Flexor carpi radialis (-) flexor carpi ulnaris (-) Box and Block test (+exp1) 10m Walk test self paced Gait velocity (+exp1) self paced Stride length (+exp1) as quick as possible velocity (+exp1) as quick as possible stride length (-) Motor Activity log Amount of Use (-) Quality of movement (-) ABILHAND (-) Kinematics Wrist normalized movement time (-) Wrist normalized multiple motor unit(-) normalized shoulder flexion (-) normalized elbow extension (-) max shoulder abduction (+exp1) E2 vs C: Fugl-Meyer assessment-upper extremity Proximal (-) Distal (-) Total (+exp2) Muscle tone using Myoton Biceps (-) Flexor carpi radialis (-) flexor carpi ulnaris (-) Box and Block test (+con) 10m Walk test self paced Gait velocity (+con)

		self paced Stride length (+con) as quick as possible velocity (+con) as quick as possible stride length (-) Motor Activity log Amount of Use (-) Quality of movement (-) ABILHAND (-) Kinematics Wrist normalized movement time (-) Wrist normalized multiple motor unit(-) normalized shoulder flexion (+con) normalized elbow extension (-) max shoulder abduction (+exp2) E1 vs E2: Fugl-Meyer assessment-upper extremity Proximal (-) Distal (-) Total (-) Muscle tone using Myoton Biceps (-) Flexor carpi radialis (-) flexor carpi ulnaris (-) Box and Block test (+exp1) 10m Walk test self paced Gait velocity (+exp1) self paced Stride length (+exp1) as quick as possible velocity (+exp1) as quick as possible stride length (-) Motor Activity log Amount of Use (-) Quality of movement (-) ABILHAND (-) Kinematics Wrist normalized movement time (-) Wrist normalized multiple motor unit(-) normalized shoulder flexion (-) normalized elbow extension (-) max shoulder abduction (-)
Mirror Therapy combined with NMES vs Mirror Therapy with Sham NMES or Conventional Therapy		
Xu et al. (2017) RCT (7) Nstart=69 Nend=69 TPS=Subacute A + B vs A vs 0 Also in Table 29 (Neuromuscular Electrical Stimulation (NMES))	E1: conventional rehabilitation + mirror therapy + neuromuscular electrical stimulation E2: conventional rehabilitation + mirror therapy C: conventional rehabilitation + Sham mirror therapy Duration: 240min/d, 5d/wk, for 4wks conventional rehabilitation + 30min/d mirror/sham/mirror+NMES	E1/E2 v C: 10-meter walk test (+exp1, +exp2) Brunnstrom stages of lower extremity (+exp1, +exp2) Modified Ashworth Scale (+exp1) Passive ROM (+exp1, +exp2) E1 v E2: 10-meter walk test (+exp1) Brunnstrom stages of lower extremity (-) Modified Ashworth Scale (-) Passive ROM (-)
Lee et al. (2016) RCT (6) Nstart=30	E: Mirror therapy + cyclical neuromuscular electrical stimulation + conventional physical therapy C: Conventional therapy	E vs C: Ankle Dorsiflexor Strength (+exp) Modified Ashworth Scale (-)

Nend=27 TPS=Chronic A + B vs 0 Also in Table 29 (Neuromuscular Electrical Stimulation (NMES))	Duration: 60min/d, 5d/wk, for 4wks conventional PT & 1session/d, 5d/wk, for 4wks MT + NNES	Berg Balance Scale (+exp) Timed-up-and-go (-) 6-minute Walk Test (-)
Mirror Therapy combined with FES vs Conventional Therapy		
Li et al. (2024a) RCT (6) Nstart=106 Nend=102 TPS=Subacute A + B vs B Also in Table 28 (Functional Electrical Stimulation)	E: Mirror feedback + FES C: Conventional rehab + FES Duration: 50min(20min FES, 30min Mirror), 1d/wk, 4wks	E vs C: Grounding angle of the affected foot (+exp) Single-support phase(+exp) step length(+exp) Step rate (+exp) Lindmark score(+exp) FMA(+exp) Falls index(+exp) Berg score(+exp) TUGT(+exp)
Salhab et al. (2016) RCT crossover (5) Nstart=18 Nend=18 TPS=Subacute A + B vs 0 vs C Also in Table 28 (Functional Electrical Stimulation)	E: Mirror therapy + Functional electrical stimulation C: Conventional therapy C: 50 min, 4d/wk, for 2wks CT 1wk washout Duration: E: 50 min, 4d/wk, 2 wks MT + 16min/session ES treatment C: 50 min, 4d/wk, 2 wks CT 1 wk washout	E vs C: Ankle dorsiflexion range of motion (+exp) Fugl-Meyer assessment-lower extremity (+exp) 10m Walk test (+exp)
Mirror Therapy with rTMS vs Mirror Therapy with Sham Stimulation		
Cha & Kim (2015) RCT (6) Nstart=36 Nend=31 TPS=Subacute A + B vs A Also in Table 37 (Repetitive Transcranial Magnetic Stimulation (rTMS))	E: Mirror therapy + Repetitive transcranial magnetic stimulation C: Mirror therapy + Sham stimulation Duration: 30min/d, 5d/wk for 4wks Mirror therapy & 10min/d, 5d/wk, for 4wks rTMS or Sham	E vs C: Dynamic limits of stability (+exp) Berg Balance Scale (-) Timed Up & Go Test (-) Balance Index (+exp)
Mirror Therapy with Virtual Reality vs Conventional therapy		
Miclaus et al. (2021) RCT (7) Nstart=64 Nend=64 TPS=Chronic A vs B Also in Table 26 (Virtual Reality)	E: Virtual reality (VR) therapy and mirror therapy (MT) exercises C: Standard lower extremity rehabilitation Duration: 70min/d, 5d/wk, for 2wks	E vs C: Functional Independence Measure (-) Modified Rankin Scale (-) Modified Ashworth Scale (-) Fugl Meyer Lower Extremity Assessment Motor (+exp) Passive (+exp) Pain (-) Manual Muscle Testing (+exp) Active Range of Motion (+exp) Functional Reach Test (+exp) Time Up to Go (-)
Mirror Therapy with Verbal Feedback vs Mirror Therapy Alone		
Chaudhary et al. (2022) RCT (7) Nstart=30	E: Visual feedback via Mirror + Verbal feedback + Conventional treatment (static and dynamic balance training)	E vs C: BBS (+exp)

Nend=30 TPS=Chronic A + B vs A Also in Table 11 (Balance Training); Table 15 (Biofeedback)	C: Visual feedback via Mirror + Conventional treatment (static and dynamic balance training) Duration: 30 min/d, 3d/wk, 8 wks	
Additional Comparisons from the Source Dataset		
Tyson et al. (2015) RCT (8) Nstart=94 Nend=85 TPS=Acute A vs B	E: At home Mirror therapy + Usual care C: At home Lower limb exercises + Usual care Duration: 30min/d, 7d/wk, 4wks	E vs C: Motricity Index (-) Grip strength (-) Rivermead Assessment of Sensory Perception (-) Modified Ashworth Scale (-) Star Cancellation test (-) Box and Block (-) Action Research Arm Test (-) Rivermead Mobility Index (-) Brunel Balance Assessment (-)
Cross-Referenced RCTs: Combined or Comparative Interventions

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1b	At home Mirror therapy + Usual care may not have a difference in efficacy when compared to At home Lower limb exercises + Usual care for improving spasticity.	1	Tyson et al. 2015
1b	Treadmill Training with Mirror Therapy may not have a difference in efficacy when compared to Treadmill Training with Sham for improving spasticity.	1	Broderick et al. 2019
1b	Home based Isometric Unilateral Strength Training with Mirror Therapy may not have a difference in efficacy when compared to Home based Isometric Unilateral Strength Training for improving spasticity.	1	Simpson et al. 2019
1b	Electrical stimulation with mirror therapy may not have a difference in efficacy when compared to Sham electrical stimulation with sham mirror therapy for improving spasticity.	1	Lee & Lee 2019b
1b	Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy may not have a difference in efficacy when compared to Conventional therapy for improving spasticity.	1	Lee et al. 2016

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Mirror Therapy may produce greater improvements in range of motion than Conventional Therapy or Sham Therapy.	1	Salem et al. 2015
1b	There is conflicting evidence about the effect of Mirror Therapy with Stimulation when compared to Mirror Therapy or Task Oriented Training for improving range of motion.	1	Lin et al. 2014a
1b	Mirror Therapy combined with neuromuscular electrical stimulation may not have a difference in efficacy when compared to Mirror Therapy with Sham neuromuscular electrical stimulation or Conventional Therapy for improving range of motion.	1	Xu et al. 2017
2	Mirror Therapy combined with functional electrical stimulation may produce greater improvements in range of motion than Conventional Therapy.	1	Salhab et al. 2016
1b	Mirror Therapy with Virtual Reality may produce greater improvements in range of motion than Conventional therapy.	1	Miclaus et al. 2021
2	Mirror therapy with Functional electrical stimulation may produce greater improvements in range of motion than Conventional therapy.	1	Salhab et al. 2016

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Mirror Therapy may produce greater improvements in neurophysiological measures than Conventional Therapy or Sham Therapy.	1	Cui et al. 2022

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Mirror therapy may not have a difference in efficacy when compared to Mirror therapy with Mesh glove (afferent stimulation) for improving sensory and proprioceptive function.	1	Lee et al. 2015c
1b	Mirror Therapy with Stimulation may not have a difference in efficacy when compared to Mirror Therapy or Task Oriented Training for improving sensory and proprioceptive function.	1	Lee et al. 2015c
1b	Mirror therapy or Mirror therapy with Mesh glove (afferent stimulation) may not have a difference in efficacy when compared to Mirror therapy with Sham mesh glove for improving sensory and proprioceptive function.	1	Lee et al. 2015c
1b	At home Mirror therapy + Usual care may not have a difference in efficacy when compared to At home Lower limb exercises + Usual care for improving sensory and proprioceptive function.	1	Tyson et al. 2015

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Mirror Therapy may produce greater improvements in activities of daily living than Conventional Therapy or Sham Therapy.	4	Cui et al. 2022; Ikizler May et al. 2020; Wang et al. 2017; Sütbeyaz et al. 2007
1b	Mirror therapy may result in lesser improvements in activities of daily living when compared to Mirror therapy with Mesh glove (afferent stimulation).	1	Lee et al. 2015c
1b	Mirror Therapy with Stimulation may not have a difference in efficacy when compared to Mirror Therapy or Task Oriented Training for improving activities of daily living.	1	Lee et al. 2015c
1b	Mirror therapy with Mesh glove (afferent stimulation) may not have a difference in efficacy when compared to Mirror therapy with Sham mesh glove for improving activities of daily living.	1	Lee et al. 2015c
1b	Mirror therapy may result in lesser improvements in activities of daily living when compared to Mirror therapy with Sham mesh glove.	1	Lee et al. 2015c
1b	Mirror Therapy with Virtual Reality may not have a difference in efficacy when compared to Conventional therapy for improving activities of daily living.	1	Miclaus et al. 2021
2	Home rehabilitation, then Clinic rehabilitation may not have a difference in efficacy when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice for improving activities of daily living.	1	Hsieh et al. 2018

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Mirror Therapy may not have a difference in efficacy when compared to Conventional Therapy or Sham Therapy for improving gait speed.	5	Arya et al. 2019; Simpson et al. 2019; Bhoraniya et al. 2018; Ji & Kim 2015; Salem et al. 2015
1b	Treadmill Training Combined with Mirror Therapy may not have a difference in efficacy when compared to Treadmill Training for improving gait speed.	1	Broderick et al. 2019
2	Mirror Therapy with Task Oriented Training may produce greater improvements in gait speed than Task Oriented Training.	1	Choi et al. 2015c

1b	Mirror therapy may not have a difference in efficacy when compared to Mirror therapy with Mesh glove (afferent stimulation) for improving gait speed.	1	Lee et al. 2015c
1a	There is conflicting evidence about the effect of Mirror Therapy with Stimulation when compared to Mirror Therapy or Task Oriented Training for improving gait speed.	2	Lee et al. 2015c; Lin et al. 2014a
1b	Mirror therapy or Mirror therapy with Mesh glove (afferent stimulation) may not have a difference in efficacy when compared to Mirror therapy with Sham mesh glove for improving gait speed.	1	Lee et al. 2015c
1b	Mirror Therapy with Conventional care may result in lesser improvements in gait speed when compared to Task-oriented training with Conventional care.	1	Lin et al. 2014a
1b	Mirror Therapy combined with neuromuscular electrical stimulation may produce greater improvements in gait speed than Mirror Therapy with Sham neuromuscular electrical stimulation or Conventional Therapy.	1	Xu et al. 2017
2	Mirror Therapy combined with functional electrical stimulation may produce greater improvements in gait speed than Conventional Therapy.	1	Salhab et al. 2016
1b	Treadmill Training with Mirror Therapy may not have a difference in efficacy when compared to Treadmill Training with Sham for improving gait speed.	1	Broderick et al. 2019
1b	Home based Isometric Unilateral Strength Training with Mirror Therapy may not have a difference in efficacy when compared to Home based Isometric Unilateral Strength Training for improving gait speed.	1	Simpson et al. 2019
1b	Electrical stimulation with mirror therapy may produce greater improvements in gait speed than Sham electrical stimulation with sham mirror therapy.	1	Lee & Lee 2019b
2	Home rehabilitation, then Clinic rehabilitation may not have a difference in efficacy when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice for improving gait speed.	1	Hsieh et al. 2018
2	Mirror therapy with Functional electrical stimulation may produce greater improvements in gait speed than Conventional therapy.	1	Salhab et al. 2016

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Mirror Therapy may produce greater improvements in gait endurance than Conventional Therapy or Sham Therapy.	1	Ikizler May et al. 2020
1b	Treadmill Training Combined with Mirror Therapy may not have a difference in efficacy when compared to Treadmill Training for improving gait endurance.	1	Broderick et al. 2019
1b	Mirror Therapy combined with neuromuscular electrical stimulation may not have a difference in efficacy when compared to Mirror Therapy with Sham neuromuscular electrical stimulation or Conventional Therapy for improving gait endurance.	1	Lee et al. 2016
1b	Treadmill Training with Mirror Therapy may not have a difference in efficacy when compared to Treadmill Training with Sham for improving gait endurance.	1	Broderick et al. 2019
1b	Low frequency (1Hz) Repetitive Transcranial Magnetic Stimulation with mirror therapy may produce greater improvements in gait endurance than Sham repetitive transcranial magnetic stimulation with mirror therapy.	1	Cha et al. 2017a

1b	Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy may not have a difference in efficacy when compared to Conventional therapy for improving gait endurance.	1	Lee et al. 2016

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Mirror Therapy may produce greater improvements in functional mobility than Conventional Therapy or Sham Therapy.	8	Cui et al. 2022; Verma et al. 2021; Ikizler May et al. 2020; Arya et al. 2019; Simpson et al. 2019; Wang et al. 2017; Mohan et al. 2013; Sütbeyaz et al. 2007
1b	There is conflicting evidence about the effect of Mirror Therapy with Task Oriented Training when compared to Task Oriented Training for improving functional mobility.	2	Cha et al. 2016; Choi et al. 2015c
1b	Mirror Therapy combined with neuromuscular electrical stimulation may not have a difference in efficacy when compared to Mirror Therapy with Sham neuromuscular electrical stimulation or Conventional Therapy for improving functional mobility.	1	Lee et al. 2016
1b	Mirror Therapy with repetitive transcranial magnetic stimulation may not have a difference in efficacy when compared to Mirror Therapy with Sham Stimulation for improving functional mobility.	1	Cha & Kim 2015
1b	At home Mirror therapy + Usual care may not have a difference in efficacy when compared to At home Lower limb exercises + Usual care for improving functional mobility.	1	Tyson et al. 2015
1b	Home based Isometric Unilateral Strength Training with Mirror Therapy may not have a difference in efficacy when compared to Home based Isometric Unilateral Strength Training for improving functional mobility.	1	Simpson et al. 2019
2	Home rehabilitation, then Clinic rehabilitation may produce greater improvements in functional mobility than Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice.	1	Hsieh et al. 2018
1b	Low frequency (1Hz) Repetitive Transcranial Magnetic Stimulation with mirror therapy may produce greater improvements in functional mobility than Sham repetitive transcranial magnetic stimulation with mirror therapy.	1	Cha et al. 2017a
1b	Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy may not have a difference in efficacy when compared to Conventional therapy for improving functional mobility.	1	Lee et al. 2016

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Mirror Therapy may produce greater improvements in balance than Conventional Therapy or Sham Therapy.	6	Cui et al. 2022; Armat et al. 2022; Verma et al. 2021; Ikizler May et al. 2020; Wang et al. 2017; Mohan et al. 2013
1b	Mirror Therapy with Task Oriented Training may produce greater improvements in balance than Task Oriented Training.	1	Cha et al. 2016
1b	Mirror Therapy combined with neuromuscular electrical stimulation may produce greater improvements in balance than Mirror Therapy with Sham neuromuscular electrical stimulation or Conventional Therapy.	1	Lee et al. 2016

1b	Mirror Therapy combined with functional electrical stimulation may produce greater improvements in balance than Conventional Therapy.	1	Li et al. 2024a
1b	Mirror Therapy with repetitive transcranial magnetic stimulation may not have a difference in efficacy when compared to Mirror Therapy with Sham Stimulation for improving balance.	1	Cha & Kim 2015
1b	There is conflicting evidence about the effect of Mirror Therapy with Virtual Reality when compared to Conventional therapy for improving balance.	1	Miclaus et al. 2021
1b	Mirror Therapy with Verbal Feedback may produce greater improvements in balance than Mirror Therapy Alone.	1	Chaudhary et al. 2022
1b	At home Mirror therapy + Usual care may not have a difference in efficacy when compared to At home Lower limb exercises + Usual care for improving balance.	1	Tyson et al. 2015
1b	Electrical stimulation with mirror therapy may produce greater improvements in balance than Sham electrical stimulation with sham mirror therapy.	1	Lee & Lee 2019b
1b	Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy may produce greater improvements in balance than Conventional therapy.	1	Lee et al. 2016

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Mirror Therapy combined with functional electrical stimulation may produce greater improvements in falls and fear of falling than Conventional Therapy.	1	Li et al. 2024a

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Mirror Therapy may not have a difference in efficacy when compared to Conventional Therapy or Sham Therapy for improving quality of life.	1	Simpson et al. 2019
1b	Home based Isometric Unilateral Strength Training with Mirror Therapy may not have a difference in efficacy when compared to Home based Isometric Unilateral Strength Training for improving quality of life.	1	Simpson et al. 2019
2	There is conflicting evidence about the effect of Home rehabilitation, then Clinic rehabilitation when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice for improving quality of life.	1	Hsieh et al. 2018

Other Associated Outcome Measures

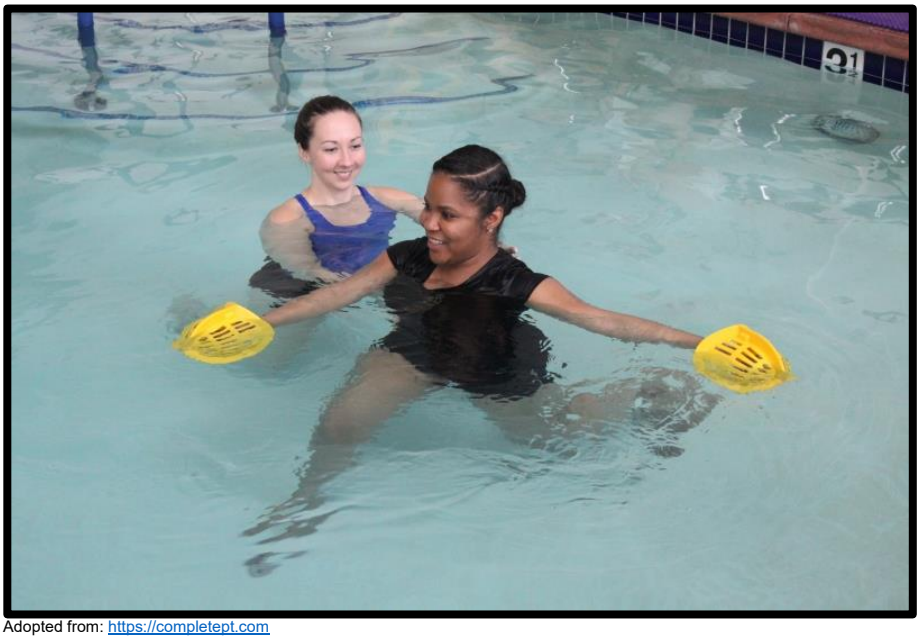
COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	At home Mirror therapy + Usual care may not have a difference in efficacy when compared to At home Lower limb exercises + Usual care for improving cognition.	1	Tyson et al. 2015

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Mirror therapy may result in lesser improvements in upper extremity function when compared to Mirror therapy with Mesh glove (afferent stimulation).	1	Lee et al. 2015c
1a	Mirror Therapy with Stimulation may not have a difference in efficacy when compared to Mirror Therapy or Task Oriented Training for improving upper extremity function.	2	Lee et al. 2015c; Lin et al. 2014a
1b	Mirror therapy with Mesh glove (afferent stimulation) may not have a difference in efficacy when compared to Mirror therapy with Sham mesh glove for improving upper extremity function.	1	Lee et al. 2015c
1b	Mirror therapy may result in lesser improvements in upper extremity function when compared to Mirror therapy with Sham mesh glove.	1	Lee et al. 2015c
1b	There is conflicting evidence about the effect of Mirror Therapy with Conventional care when compared to Task-oriented training with Conventional care for improving upper extremity function.	1	Lin et al. 2014a
1b	At home Mirror therapy + Usual care may not have a difference in efficacy when compared to At home Lower limb exercises + Usual care for improving upper extremity function.	1	Tyson et al. 2015
2	There is conflicting evidence about the effect of Home rehabilitation, then Clinic rehabilitation when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice for improving upper extremity function.	1	Hsieh et al. 2018

Key Points

- Mirror Therapy may be beneficial for improving motor recovery, biomechanical gait measures, biomechanical balance measures, range of motion, neurophysiological measures, activities of daily living, gait endurance, functional mobility, and balance, but not muscle strength, spasticity, gait speed, and quality of life, after stroke when compared to Conventional Therapy or Sham Therapy.
- Treadmill Training Combined with Mirror Therapy may not be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Treadmill Training.
- Mirror Therapy with Task Oriented Training may be beneficial for improving biomechanical balance measures, gait speed, and balance after stroke when compared to Task Oriented Training; the literature is mixed regarding muscle strength and functional mobility.
- Mirror therapy may not be beneficial for improving motor recovery, sensory and proprioceptive function, and gait speed after stroke when compared to Mirror therapy with Mesh glove (afferent stimulation); the literature is mixed regarding spasticity; Mirror therapy may result in lesser improvements in activities of daily living when compared to Mirror therapy with Mesh glove (afferent stimulation).
- Mirror Therapy with Stimulation may not be beneficial for improving motor recovery, spasticity, sensory and proprioceptive function, and activities of daily living after stroke when compared to Mirror Therapy or Task Oriented Training; the literature is mixed regarding biomechanical gait measures, range of motion, and gait speed.
- Mirror Therapy combined with neuromuscular electrical stimulation may be beneficial for improving muscle strength, gait speed, and balance, but not motor recovery, spasticity, range of motion, gait endurance, and functional mobility, after stroke when compared to Mirror Therapy with Sham neuromuscular electrical stimulation or Conventional Therapy.
- Mirror Therapy combined with functional electrical stimulation may be beneficial for improving motor recovery, biomechanical gait measures, range of motion, gait speed, balance, and falls and fear of falling after stroke when compared to Conventional Therapy.
- Mirror Therapy with repetitive transcranial magnetic stimulation may be beneficial for improving biomechanical balance measures, but not functional mobility and balance, after stroke when compared to Mirror Therapy with Sham Stimulation.

- Mirror Therapy with Virtual Reality may be beneficial for improving motor recovery and range of motion, but not spasticity and activities of daily living, after stroke when compared to Conventional therapy; the literature is mixed regarding balance.
- Mirror Therapy with Verbal Feedback may be beneficial for improving balance after stroke when compared to Mirror Therapy Alone.
- At home Mirror therapy + Usual care may not be beneficial for improving muscle strength, spasticity, sensory and proprioceptive function, functional mobility, and balance after stroke when compared to At home Lower limb exercises + Usual care.
- Treadmill Training with Mirror Therapy may not be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Treadmill Training with Sham.
- Home based Isometric Unilateral Strength Training with Mirror Therapy may not be beneficial for improving muscle strength, spasticity, gait speed, functional mobility, and quality of life after stroke when compared to Home based Isometric Unilateral Strength Training.
- Electrical stimulation with mirror therapy may be beneficial for improving muscle strength, gait speed, and balance, but not biomechanical gait measures and spasticity, after stroke when compared to Sham electrical stimulation with sham mirror therapy.
- Home rehabilitation, then Clinic rehabilitation may be beneficial for improving functional mobility, but not activities of daily living and gait speed, after stroke when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice; the literature is mixed regarding quality of life.
- Low frequency (1Hz) Repetitive Transcranial Magnetic Stimulation with mirror therapy may be beneficial for improving biomechanical balance measures, gait endurance, and functional mobility after stroke when compared to Sham repetitive transcranial magnetic stimulation with mirror therapy.
- Mirror therapy with Functional electrical stimulation may be beneficial for improving motor recovery, range of motion, and gait speed after stroke when compared to Conventional therapy.
- Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy may be beneficial for improving muscle strength and balance, but not spasticity, gait endurance, and functional mobility, after stroke when compared to Conventional therapy.
- Mirror therapy may not be beneficial for improving motor recovery, spasticity, sensory and proprioceptive function, and gait speed after stroke when compared to Mirror therapy with Sham mesh glove; Mirror therapy may result in lesser improvements in activities of daily living when compared to Mirror therapy with Sham mesh glove.
- Mirror therapy with Mesh glove (afferent stimulation) may not be beneficial for improving motor recovery, sensory and proprioceptive function, activities of daily living, and gait speed after stroke when compared to Mirror therapy with Sham mesh glove; the literature is mixed regarding spasticity.
- Mirror Therapy with Conventional care may result in lesser improvements in gait speed when compared to Task-oriented training with Conventional care; the literature is mixed regarding biomechanical gait measures.



Summary of Key Points: Mirror Therapy

Intervention	Control(s)	Function domain(s)	Effect
Mirror Therapy	Conventional Therapy or Sham Therapy	Motor recovery, biomechanical gait measures, biomechanical balance measures, range of motion, neurophysiological measures, activities of daily living, gait endurance, functional mobility, balance	+
Mirror Therapy	Conventional Therapy or Sham Therapy	Muscle strength, spasticity, gait speed, quality of life	–
Treadmill Training Combined with Mirror Therapy	Treadmill Training	Motor recovery, spasticity, gait speed, gait endurance	–
Mirror Therapy with Task Oriented Training	Task Oriented Training	Biomechanical balance measures, gait speed, balance	+

Mirror Therapy with Task Oriented Training	Task Oriented Training	Muscle strength, functional mobility	=
Mirror therapy	Mirror therapy with Mesh glove (afferent stimulation)	Motor recovery, sensory and proprioceptive function, activities of daily living, gait speed	–
Mirror therapy	Mirror therapy with Mesh glove (afferent stimulation)	Activities of daily living	–
Mirror Therapy with Stimulation	Mirror Therapy or Task Oriented Training	Motor recovery, spasticity, sensory and proprioceptive function, activities of daily living	–
Mirror Therapy with Stimulation	Mirror Therapy or Task Oriented Training	Biomechanical gait measures, range of motion, gait speed	=
Mirror Therapy with Stimulation	Mirror Therapy or Task Oriented Training	Motor recovery	–
Mirror Therapy with Stimulation	Mirror Therapy or Task Oriented Training	Biomechanical gait measures	=
Mirror Therapy combined with neuromuscular electrical stimulation	Mirror Therapy with Sham neuromuscular electrical stimulation or Conventional Therapy	Muscle strength, gait speed, balance	+
Mirror Therapy combined with neuromuscular electrical stimulation	Mirror Therapy with Sham neuromuscular electrical stimulation or Conventional Therapy	Motor recovery, spasticity, range of motion, gait endurance, functional mobility	–
Mirror Therapy combined with functional electrical stimulation	Conventional Therapy	Motor recovery, biomechanical gait measures, range of motion, gait speed, balance, falls and fear of falling	+
Mirror Therapy with repetitive transcranial magnetic stimulation	Mirror Therapy with Sham Stimulation	Biomechanical balance measures	+
Mirror Therapy with repetitive transcranial magnetic stimulation	Mirror Therapy with Sham Stimulation	Functional mobility, balance	–
Mirror Therapy with Virtual Reality	Conventional therapy	Motor recovery, range of motion	+
Mirror Therapy with Virtual Reality	Conventional therapy	Spasticity, activities of daily living	–
Mirror Therapy with Virtual Reality	Conventional therapy	Balance	=
Mirror Therapy with Verbal Feedback	Mirror Therapy Alone	Balance	+
At home Mirror therapy + Usual care	At home Lower limb exercises + Usual care	Muscle strength, spasticity, sensory and proprioceptive function, functional mobility, balance	–
Treadmill Training with Mirror Therapy	Treadmill Training with Sham	Motor recovery, spasticity, gait speed, gait endurance	–
Home based Isometric Unilateral Strength Training with Mirror Therapy	Home based Isometric Unilateral Strength Training	Muscle strength, spasticity, gait speed, functional mobility, quality of life	–
Electrical stimulation with mirror therapy	Sham electrical stimulation with sham mirror therapy	Muscle strength, gait speed, balance	+
Electrical stimulation with mirror therapy	Sham electrical stimulation with sham mirror therapy	Biomechanical gait measures, spasticity	–
Home rehabilitation, then Clinic rehabilitation	Clinic rehabilitation, then home rehabilitation. Both settings	Functional mobility	+

	involved mirror therapy and functional task practice		
Home rehabilitation, then Clinic rehabilitation	Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice	Activities of daily living, gait speed	–
Home rehabilitation, then Clinic rehabilitation	Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice	Quality of life	=
Low frequency (1Hz) Repetitive Transcranial Magnetic Stimulation with mirror therapy	Sham repetitive transcranial magnetic stimulation with mirror therapy	Biomechanical balance measures, gait endurance, functional mobility	+
Mirror therapy with Functional electrical stimulation	Conventional therapy	Motor recovery, range of motion, gait speed	+
Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy	Conventional therapy	Muscle strength, balance	+
Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy	Conventional therapy	Spasticity, gait endurance, functional mobility	–
Mirror therapy	Mirror therapy with Sham mesh glove	Motor recovery, spasticity, sensory and proprioceptive function, activities of daily living, gait speed	–
Mirror therapy with Mesh glove (afferent stimulation)	Mirror therapy with Sham mesh glove	Motor recovery, sensory and proprioceptive function, activities of daily living, gait speed	–
Mirror Therapy with Conventional care	Task-oriented training with Conventional care	Biomechanical gait measures	=
Mirror Therapy with Conventional care	Task-oriented training with Conventional care	Gait speed	–
Mirror therapy	Mirror therapy with Mesh glove (afferent stimulation)	Spasticity	=
Mirror therapy with Mesh glove (afferent stimulation)	Mirror therapy with Sham mesh glove	Spasticity	=

Aquatic Therapy

Adopted from: https://completept.com

Aquatic therapy employs the natural properties of water (i.e. buoyancy, hydrostatic pressure, hydrodynamic forces, thermodynamics and viscosity) to act as a rehabilitation intervention in supporting weight and offsetting gravity during exercises related to balance and gait performed in water (Becker, 2009).

Aquatic therapies may vary, with some forms including traditional exercises, neurodevelopmental techniques, proprioceptive neuromuscular facilitation, and task-specific training. The Halliwick Method is an example of a motor rehabilitation program that is based on neurodevelopmental techniques, in which core stability is a major focus (Martin, 1981). The Bad Ragaz Ring Method is an example of a motor rehabilitation program that is based on proprioceptive neuromuscular facilitation techniques, in which improving range of motion is a major focus (Boyle, 1981). Alternative and complementary medicine techniques have also been integrated into aquatic therapy programs, examples include Ai chi, which is derived from tai chi, as well as Watsu, which is derived from shiatsu (Lutz, 1999; Ross & Presswalla, 1998).

A total of 29 RCTs were found that evaluated aquatic therapy for lower extremity motor rehabilitation. Fourteen RCTs compared Aquatic Therapy with Conventional Therapy (Bei et al. 2023; Vakilian et al. 2021; Ku et al. 2020; Eyvaz et al. 2018; Cha et al. 2017b; Chan et al. 2017a; Park et al. 2016; Zhu et al. 2016a; Kim et al. 2015b; Kim et al. 2015b; Furnari et al. 2014; Tripp et al. 2014; Park et al. 2011a; Noh et al. 2008). One RCT compared Aquatic Therapy with Land-Based Upper Extremity Exercises (Chu et al. 2004). Seven RCTs compared Aquatic Treadmill Walking or Aerobic Therapy with Overground or Treadmill Walking or Cycle Ergometer (Kim et al. 2022a; Kim et al. 2020d; Franciulli et al. 2019; Lee et al. 2018d; Han et al. 2018; Zhang et al. 2016; Park et al. 2012). Two RCTs compared Aquatic Ai Chi Therapy with Dry Land Therapy with Aquatic Ai Chi Therapy (Perez-de la Cruz et al. 2021; Perez-de la Cruz et al. 2020). Two RCTs compared Dual-Task Aquatic Training with Neurodevelopmental Techniques or Land-Based Dual Motor Task (Saleh et al. 2019; Kim et al. 2016a). One RCT compared Aquatic Therapy with Strength Training with Aquatic Therapy (Gu et al. 2023). One RCT compared Sequential Preparatory Approach Aquatic Therapy with Standard Aquatic Therapy (Temperoni et al. 2020).

In addition, two RCTs in which aquatic therapy formed part of a combined or comparative intervention are cross-referenced at the end of Table 20; their primary listings appear in other tables.

The methodological details and results of all 29 RCTs are presented in Table 20.

Table 20. RCTs Evaluating Aquatic Therapy for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)

Time post stroke category Study design		
Aquatic Therapy vs Conventional Therapy		
Bei et al. (2023) RCT (4) Nstart=160 Nend=160 TPS=Acute A vs 0	E: Hydrotherapy C: Conventional rehab Duration: 60min/d(30min conventional, 30min Hydrotherapy), 6d/wk, 8wks	E vs C: FMA(+exp) FAC(+exp): BBS(+exp): MBI(+exp): NIHSS(+exp) MRS(+exp)
Vakilian et al. (2021) RCT (5) Nstart=36 Nend=36 TPS=Chronic A1 vs A2 vs 0	E1: Aqua therapy in shallow water E2: Aqua therapy in deep water C: Usual treatment Duration: 30min/d, 3d/wk, for 6wks	E1 v C: Static balance (+exp1) Semi-dynamic balance (+exp1) E2 v C: Static balance (+exp2) Semi-dynamic balance (+exp2) E1 v E2: Static balance (-) Semi-dynamic balance (-)
Ku et al. (2020) RCT (8) Nstart=20 Nend=20 TPS=Chronic A vs B	E: Ai Chi (modified aquatic therapy) C: Conventional Water Based Exercise Duration: 60min/d, 3d/wk, for 6wks	E vs C: Berg Balance Scale (-) Limit of Stability: Movement velocity (-) Directed control (-) Max excursion (-) End excursion-AP (+exp) Fugl-Meyer Assessment Lower Extremity (+exp) Gait speed (-) Stride length (-) Stride time (-) Cadence (-)
Eyvaz et al. (2018) RCT (5) Nstart=65 Nend=60 TPS=Chronic A + B vs B vs C	E: Water based exercise (WBE) therapy + Land based exercise (LBE) C: Land based exercise Duration: E: WBE for 3d/wk, 6 wk+ LBE for 40min/d, 5d/wk, for 6wks C: LBE for 40min/d, 5d/wk, for 6wks	E vs C: Berg Balance Scale (+con) Functional Independence Measure (-) Timed Up and Go scale (-) Static Balance Index (-) Dynamic Balance Index (-) Isokinetic Peak torque affected side quadriceps 90(-) affected side quadriceps 120 (-) unaffected side quadriceps 90(-) unaffected side quadriceps 120 (-) affected side hamstrings 90 (-) affected side hamstrings 120 (-) unaffected side hamstrings 90(-) unaffected side hamstrings 120 (-) Short Form 36 physical function (-) role limitations due to physical functioning (-) social function (-) general mental health (-)

		role limitations due to emotional problems (-) vitality (+exp) pain (-) general health (-) pain (-)
Cha et al. (2017b) RCT (8) Nstart=22 Nend=22 TPS=Chronic A vs 0	E: Aquatic therapy (Bad Ragaz Ring Method) + conventional therapy C: Conventional therapy Duration: 60min/d, 3d/wk for 6wks	E vs C: Muscle activation by EMG (+exp) Balance index (+exp) Timed Up and Go (-)
Chan et al. (2017a) RCT (5) Nstart=32 Nend=25 TPS=Subacute A + B vs B	E: In-water exercise training + Land exercise training C: Land exercise training Duration: 60min/d, 2d/wk, for 6wks	E vs C: Berg Balance Score (-) Community Balance and Mobility Score (-) Timed Up and Go Test (-) 2-Minute Walk Test (-)
Park et al. (2016) RCT (5) Nstart=28 Nend=28 TPS=Chronic A vs B Also in Table 4 (Trunk Training)	E: Aquatic therapy (Halliwick, Watsu, and Trunk Training) C: Trunk control exercises Duration: 30min/d, 3d/wk, 4wks	E vs C: Gait Speed (-) Walking cycle (+con) Affected side stance phase (-) Affected side stride length (+con) Symmetry index of stance phase (-) Symmetry index of stride length (-)
Zhu et al. (2016a) RCT (8) Nstart=28 Nend=28 TPS=Chronic A vs 0	E: Aquatic therapy C: Conventional therapy Duration: 45min/d, 5d/wk for 4wks	E vs C: Berg Balance Scale (-) Functional Reach Test (+exp) Timed Up and Go Test (-) 2-Minute Walk Test (+exp)
Kim et al. (2015f) RCT (4) Nstart=20 Nend=20 TPS=Chronic A vs B Also in Table 12 (Stretching or Mobilization Exercises)	E: Aquatic therapy (based on proprioceptive neuromuscular facilitation) C: Proprioceptive neuromuscular facilitation on the ground Duration: 30min/d, 5d/wk for 6wks	E vs C: Berg Balance Scale (+exp) Timed Up and Go Test (+exp) Functional Reach Test (+exp) One Leg Stand Test (+exp) Functional Independence Measure (+exp)
Kim et al. (2015b) RCT (4) Nstart=20 Nend=20 TPS=Chronic A vs 0 Also in Table 12 (Stretching or Mobilization Exercises)	E: Aquatic therapy (based on proprioceptive neuromuscular facilitation) C: Conventional therapy Duration: 30min/d, 5d/wk for 6wks conventional rehabilitation for both groups	E vs C: Berg Balance Scale (+exp) Functional Reach Test (+exp) 10-Meter Walk Test (+exp) Timed Up and Go Test (+exp)
Furnari et al. (2014) RCT (5) Nstart=40 Nend=40 TPS=Chronic	E: Hydrokinesytherapy + Conventional PT C: Conventional PT Duration: E: 60min/d, 3d/wk, for 8wks hydrokinesytherapy + 60min/d, 3d/wk, for	E vs C: Plantar surface eyes open (-) eyes closed (-) Plantar load

A vs 0	8wks conventional PT; C: 60min/d, 6d/wk, for 8wks conventional PT	eyes open (-) eyes closed (-) Length of ball eyes open (+exp) eyes closed (+exp) Speed (+exp) Semistep length (+exp) Cadence (+exp) Stance phase (+exp) Swing phase (+exp) Double support phase (+exp)
Tripp et al. (2014) RCT (7) Nstart=30 Nend=27 TPS=Subacute A vs 0	E: Aquatic therapy (Halliwick therapy) + conventional therapy C: Conventional therapy Duration: E: 45min/d, 2d/wk, for 2wks conventional PT + 45min/d, 3d/wk, for 2wks aquatic therapy ; C: 45min/d, 5d/wk, for 2wks conventional PT	E vs C: Berg Balance Scale (-) Functional reach (-) Functional Ambulation Categories (+exp) Rivermead Mobility Index (-)
Park et al. (2011a) RCT (4) Nstart=44 Nend=44 TPS=Chronic A vs 0	E: Aquatic therapy C: Conventional therapy Duration: 35min/d, 6d/wk for 6wks	E vs C: Performance-Oriented Mobility Assessment (+exp) Joint Position Sense (+exp)
Noh et al. (2008) RCT (4) Nstart=25 Nend=20 TPS=Chronic A vs 0	E: Aquatic therapy (Halliwick and Ai Chi methods) C: Conventional therapy Duration: 60min/d, 3d/wk for 8wks	E vs C: Berg Balance Scale (+exp) Balance assessment Rising from a chair affected (-) Rising from a chair intact (-) Weight shift laterally affected (-) Weight shift laterally intact (-) Weight shift forward affected (+exp) Weight shift forward intact (-) Weight shift backward affected (+exp) Weight shift backward intact (-) Modified Motor Assessment Scale (-) Muscle strength Knee extensor peak torque affected (-) Knee extensor peak torque intact (-) Knee flexor peak torque affected (+exp) Knee flexor peak torque intact (-) Back extensor (-) Back flexor (-)
Aquatic Therapy vs Land-Based Upper Extremity Exercises		
Chu et al. (2004) RCT (6) Nstart=13 Nend=12 TPS=Chronic A vs B	E: Group aqua therapy C: Arm function program Duration: 60min/d, 3d/wk, for 8wks	E vs C: VO2 Max (+exp) Maximal Workload (+exp) 8 Meter Walk Test Self Selected Gait Speed (+exp) Berg Balance Scale (-) Isokinetic Muscle Strength of Knee and Hip Paretic Side (+exp) Nonparetic Side (-)

Aquatic Treadmill Walking or Aerobic Therapy vs Overground or Treadmill Walking or Cycle Ergometer		
Kim et al. (2022a) RCT (7) Nstart=22 Nend=22 TPS=Chronic A vs B Also in Table 9 (Treadmill Training)	E: Underwater Treadmill gait training + conventional rehabilitation C: Overground gait training + conventional rehabilitation Duration: 60min/d, 5d/wk, 12 wks conventional rehabilitation & 30min/d, 2d/wk, 12 wks gait training	E vs C: Step length (-) Step length difference (-) Stance time (-) Swing time (-) Step time difference (+exp) Walking velocity (-) Maximal Voluntary Volume (+exp)
Kim et al. (2020d) RCT (7) Nstart=22 Nend=21 TPS=Chronic A vs B	E: Underwater gait training + conventional therapy C: Overground gait training + conventional rehabilitation 60min/d, 5d/wk, for 12wks conventional therapy & Duration: 60min/d, 5d/wk, 12 wks conventional therapy & 30min/d, 2d/wk, 12 wks gait training	E vs C: Postural Assessment Stroke Scale (+exp) Center of Pressure - Path length (-) Path velocity (-) Stance time (second) (-) Swing time (second) (-) Step time difference (second) (-) Step length (cm) (-) Step length difference (cm) (-) Walking velocity (cm/second) (-)

Aquatic Ai Chi Therapy with Dry Land Therapy vs Aquatic Ai Chi Therapy		
Perez-de la Cruz et al. (2021) RCT (8) Nstart=45 Nend=45 TPS=Chronic A + B vs A vs B	E1: Aquatic Ai Chi therapy + Dry land therapy E2: Aquatic Ai Chi therapy C: training on dry land Duration: 45min/d, 2d/wk, for 12wks	E1 vs E2: Berg balance scale(+exp2) tandem stance (-) five time sit-to-stand test (+exp2) timed up and go test (-) E1/E2 vs C: Berg balance scale(+exp2) tandem stance (+exp1)(+exp2) five time sit-to-stand test (+exp1)(+exp2) timed up and go test (+exp1)(+exp2)
Perez-de la Cruz et al. (2020) RCT (8) Nstart=40 Nend=40 TPS=Chronic A + B vs A vs B	E1: Aquatic Ai Chi therapy + Dry land therapy E2: Aquatic Ai Chi therapy C: Training on dry land Duration: 45-50min/d, 2d/wk, for 12wks dry land therapy/aquatic therapy & 45-50min/d, 4d/wk, for 12wks combined group alternating dry and aquatic training	E1 vs E2: Pain Visual Analog Scale (-) Tinetti test (-) 360 degrees turn test (+exp2) 30-Second Sit-to-Stand Test (+exp1) Single leg stance (no stat) E1/E2 vs C: Pain Visual Analog Scale (+exp1, +exp2) Tinetti test (+exp1, +exp2) 360 degrees turn test (+exp1, +exp2) 30-Second Sit-to-Stand Test (+exp1) Single leg stance (no stat)
Dual-Task Aquatic Training vs Neurodevelopmental Techniques or Land-Based Dual Motor Task		
Saleh et al. (2019) RCT (6) Nstart=50 Nend=50	E: Aquatic-based Dual-task Motor Training C: Land-based Dual-task Motor Training Duration: 45min, 3d/wk, for 6wks	E vs C: Overall Stability Index (+exp) Anteroposterior Stability Index (+exp) Mediolateral Stability Index (+exp)

TPS=Chronic A1 vs A2 Also in Table 16 (Dual-Task Training)		Walking speed (+exp) Step length affected side (+exp) non affected side (+exp) Support time affected side (+exp)
Kim et al. (2016a) RCT (4) Nstart=20 Nend=NR TPS=Chronic A vs B Also in Table 16 (Dual-Task Training)	E: Aquatic therapy (Dual-task training with upper extremity tasks) C: Neurodevelopmental techniques Duration: 1h/d, 5d/wk for 6wks	E vs C: Berg Balance Scale (+exp) Five-Time Sit to Stand Test (+exp) Functional Reach Test (+exp) 10-Meter Walk Test (+exp) Timed Up and Go Test (+exp) Functional Gait Assessment (+exp)
Aquatic Therapy with Strength Training vs Aquatic Therapy		
Gu et al. (2023) RCT (7) Nstart=61 Nend=61 TPS=Subacute A + B vs A Also in Table 21 (Strength and Resistance Training)	E: Aquatic training + under water strength training C: Aquatic training Duration: 45min/d, 5d/wk for 6wks	E vs C: Timed up and go (+exp) Berg Balance scale (+exp) 2-minute walk test (+exp) Stride length (+exp) Stride width (+exp) Stride frequency (+exp) Walking speed (+exp)
Sequential Preparatory Approach Aquatic Therapy vs Standard Aquatic Therapy		
Temperoni et al. (2020) RCT (7) Nstart=33 Nend=28 TPS=Chronic A vs B	E: Sequential preparatory approach aquatic therapy C: Standard aquatic therapy Duration: 45min/d, 2d/wk, for 4wks	E vs C: Berg Balance scale (+exp) Modified Barthel index (-) Tinetti Balance and Gait scale (-) Stroke specific QoL (+exp) Modified Ashworth scale upper limb (+exp) lower limb (+exp)
Additional Comparisons from the Source Dataset		
Lim et al. (2020) RCT (7) Nstart=22 Nend=22 TPS=Chronic A1 vs A2	E1: Waterjet resistance aquatic treadmill training + conventional PT ; E2: Ankle weight aquatic treadmill training + conventional PT Duration: 30min/d, 5d/wk for 4wks conventional PT + 30min/d, 5d/wk intervention sessions	E1 vs E2: Static balance (+exp1) Dynamic balance (+exp1) Gait velocity (+exp1) Cadence (+exp1) Step length (+exp1) Stride length (+exp1) Swing phase (+exp1)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Duran et al. (2023) RCT (7) Nstart=39 Nend=39 TPS=Chronic A vs B vs 0 Primary listing: Table 9 (Treadmill Training)	E1: anti gravity treadmill E2: underwater walking therapy C: Conventional therapy Duration: 45min/d, 3d/wk, 4wks	E1 vs C vs E2: BI(-) BBS(-) 6MWT RestingHR(-) MaxHR(+exp1) Walking distance(+exp1) Borg scale(-) Cycle ergometer Resting HR(-)

		MaxHR(+exp1) test duration(+exp1) borg scale(-) MET level(+exp1) VO2 max(+exp1)
Park et al. (2019b) RCT (7) Nstart=30 Nend=29 TPS=Chronic A vs 0 vs B Primary listing: Table 4 (Trunk Training)	E: Land-based and aquatic trunk exercises + conventional physiotherapy C: Conventional physiotherapy Duration: E: 30min/d, 5d/wk, for 4wks land/aquatic trunk exercises + 30min/d, 5d/wk, 4wks conventional physiotherapy C: 60min/d, 5d/wk, 4wks conventional physiotherapy	E vs C: Korean Trunk Impairment Scale (+exp) 5-item, 3-level Postural Assessment Scale for Stroke (+exp) 7-item, 3-level Berg Balance Scale (+exp) Functional reach test (+exp) Modified Barthel index (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Aquatic Therapy may produce greater improvements in motor recovery than Conventional Therapy.	2	Bei et al. 2023; Ku et al. 2020
1b	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving motor recovery.	1	Lee et al. 2018d

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Aquatic Therapy when compared to Conventional Therapy for improving biomechanical gait measures.	3	Ku et al. 2020; Park et al. 2016; Furnari et al. 2014
1a	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving biomechanical gait measures.	3	Kim et al. 2022a; Kim et al. 2020d; Park et al. 2012
1b	There is conflicting evidence about the effect of Aquatic Ai Chi Therapy with Dry Land Therapy when compared to Aquatic Ai Chi Therapy for improving biomechanical gait measures.	1	Perez-de la Cruz et al. 2021
1b	Dual-Task Aquatic Training may produce greater improvements in biomechanical gait measures than Neurodevelopmental Techniques or Land-Based Dual Motor Task.	1	Saleh et al. 2019
1b	Aquatic Therapy with Strength Training may produce greater improvements in biomechanical gait measures than Aquatic Therapy.	1	Gu et al. 2023

1b	Waterjet resistance aquatic treadmill training with conventional PT may produce greater improvements in biomechanical gait measures than Ankle weight aquatic treadmill training with conventional PT.	1	Lim et al. 2020

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Aquatic Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving biomechanical balance measures.	2	Eyvaz et al. 2018; Cha et al. 2017b
1b	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving biomechanical balance measures.	1	Kim et al. 2020d
1b	Dual-Task Aquatic Training may produce greater improvements in biomechanical balance measures than Neurodevelopmental Techniques or Land-Based Dual Motor Task.	1	Saleh et al. 2019

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Aquatic Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving muscle strength.	2	Eyvaz et al. 2018; Noh et al. 2008
1b	There is conflicting evidence about the effect of Aquatic Therapy when compared to Land-Based Upper Extremity Exercises for improving muscle strength.	1	Chu et al. 2004
1a	There is conflicting evidence about the effect of Aquatic Treadmill Walking or Aerobic Therapy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving muscle strength.	2	Lee et al. 2018d; Zhang et al. 2016

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving spasticity.	1	Zhang et al. 2016
1b	Sequential Preparatory Approach Aquatic Therapy may produce greater improvements in spasticity than Aquatic Therapy.	1	Temperoni et al. 2020

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Aquatic Treadmill Walking or Aerobic Therapy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving range of motion.	1	Zhang et al. 2016

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Aquatic Therapy may produce greater improvements in neurophysiological measures than Conventional Therapy.	1	Cha et al. 2017b
1b	There is conflicting evidence about the effect of Aquatic Treadmill Walking or Aerobic Therapy when compared to Overground or	3	Franciulli et al. 2019; Zhang et al. 2016; Park et al. 2012

	Treadmill Walking or Cycle Ergometer for improving neurophysiological measures.		

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Aquatic Therapy may produce greater improvements in aerobic measures than Land-Based Upper Extremity Exercises.	1	Chu et al. 2004
1a	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving aerobic measures.	2	Lee et al. 2018d; Han et al. 2018
1b	Anti gravity treadmill may produce greater improvements in aerobic measures than Conventional therapy.	1	Duran et al. 2023

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Aquatic Therapy may produce greater improvements in sensory and proprioceptive function than Conventional Therapy.	1	Park et al. 2011a

PAIN			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Aquatic Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving pain.	1	Eyvaz et al. 2018
1b	Aquatic Ai Chi Therapy with Dry Land Therapy may not have a difference in efficacy when compared to Aquatic Ai Chi Therapy for improving pain.	1	Perez-de la Cruz et al. 2020
1b	Aquatic Ai Chi therapy with Dry land therapy or Aquatic Ai Chi therapy may produce greater improvements in pain than Training on dry land.	1	Perez-de la Cruz et al. 2020

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Aquatic Therapy may produce greater improvements in activities of daily living than Conventional Therapy.	3	Bei et al. 2023; Eyvaz et al. 2018; Kim et al. 2015f
1a	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving activities of daily living.	3	Lee et al. 2018d; Han et al. 2018; Zhang et al. 2016
1b	Sequential Preparatory Approach Aquatic Therapy may not have a difference in efficacy when compared to Aquatic Therapy for improving activities of daily living.	1	Temperoni et al. 2020
1b	Anti gravity treadmill may not have a difference in efficacy when compared to Conventional therapy for improving activities of daily living.	1	Duran et al. 2023
1b	Land-based and aquatic trunk exercises with conventional physiotherapy may produce greater improvements in activities of daily living than Conventional physiotherapy or 60min/d, 5d/wk, 4wks conventional physiotherapy.	1	Park et al. 2019b

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Aquatic Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving gait speed.	4	Ku et al. 2020; Park et al. 2016; Kim et al. 2015b; Furnari et al. 2014
1b	Aquatic Therapy may produce greater improvements in gait speed than Land-Based Upper Extremity Exercises.	1	Chu et al. 2004
1a	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving gait speed.	2	Kim et al. 2022a; Kim et al. 2020d
1b	Dual-Task Aquatic Training may produce greater improvements in gait speed than Neurodevelopmental Techniques or Land-Based Dual Motor Task.	2	Saleh et al. 2019; Kim et al. 2016a
1b	Aquatic Therapy with Strength Training may produce greater improvements in gait speed than Aquatic Therapy.	1	Gu et al. 2023
1b	Waterjet resistance aquatic treadmill training with conventional PT may produce greater improvements in gait speed than Ankle weight aquatic treadmill training with conventional PT.	1	Lim et al. 2020

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Aquatic Therapy when compared to Conventional Therapy for improving gait endurance.	2	Chan et al. 2017a; Zhu et al. 2016a
1b	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving gait endurance.	1	Han et al. 2018
1b	Aquatic Therapy with Strength Training may produce greater improvements in gait endurance than Aquatic Therapy.	1	Gu et al. 2023
1b	Anti gravity treadmill may produce greater improvements in gait endurance than Conventional therapy.	1	Duran et al. 2023

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Aquatic Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving functional mobility.	9	Eyvaz et al. 2018; Cha et al. 2017b; Chan et al. 2017a; Zhu et al. 2016a; Kim et al. 2015f; Kim et al. 2015b; Tripp et al. 2014; Park et al. 2011a; Noh et al. 2008
1b	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving functional mobility.	3	Franciulli et al. 2019; Zhang et al. 2016; Park et al. 2012
1a	There is conflicting evidence about the effect of Aquatic Ai Chi Therapy with Dry Land Therapy when compared to Aquatic Ai Chi Therapy for improving functional mobility.	2	Perez-de la Cruz et al. 2021; Perez-de la Cruz et al. 2020
1a	Aquatic Ai Chi therapy with Dry land therapy may produce greater improvements in functional mobility than Training on dry land.	2	Perez-de la Cruz et al. 2021; Perez-de la Cruz et al. 2020
1a	Aquatic Ai Chi therapy may not have a difference in efficacy when compared to Training on dry land for improving functional mobility.	2	Perez-de la Cruz et al. 2021; Perez-de la Cruz et al. 2020

2	Dual-Task Aquatic Training may produce greater improvements in functional mobility than Neurodevelopmental Techniques or Land-Based Dual Motor Task.	1	Kim et al. 2016a
1b	Aquatic Therapy with Strength Training may produce greater improvements in functional mobility than Aquatic Therapy.	1	Gu et al. 2023
1b	Sequential Preparatory Approach Aquatic Therapy may not have a difference in efficacy when compared to Aquatic Therapy for improving functional mobility.	1	Temperoni et al. 2020

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Aquatic Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving balance.	9	Vakilian et al. 2021; Ku et al. 2020; Eyvaz et al. 2018; Chan et al. 2017a; Zhu et al. 2016a; Kim et al. 2015f; Kim et al. 2015b; Tripp et al. 2014; Noh et al. 2008
1b	Aquatic Therapy may not have a difference in efficacy when compared to Land-Based Upper Extremity Exercises for improving balance.	1	Chu et al. 2004
1a	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving balance.	3	Kim et al. 2020d; Franciulli et al. 2019; Lee et al. 2018d
1b	Aquatic Ai Chi Therapy with Dry Land Therapy may result in lesser improvements in balance when compared to Aquatic Ai Chi Therapy.	1	Perez-de la Cruz et al. 2021
1b	Aquatic Ai Chi therapy with Dry land therapy may not have a difference in efficacy when compared to Training on dry land for improving balance.	1	Perez-de la Cruz et al. 2021
1b	Aquatic Ai Chi therapy may produce greater improvements in balance than Training on dry land.	1	Perez-de la Cruz et al. 2021
2	Dual-Task Aquatic Training may produce greater improvements in balance than Neurodevelopmental Techniques or Land-Based Dual Motor Task.	1	Kim et al. 2016a
1b	Aquatic Therapy with Strength Training may produce greater improvements in balance than Aquatic Therapy.	1	Gu et al. 2023
1b	Sequential Preparatory Approach Aquatic Therapy may produce greater improvements in balance than Aquatic Therapy.	1	Temperoni et al. 2020
1b	Waterjet resistance aquatic treadmill training with conventional PT may produce greater improvements in balance than Ankle weight aquatic treadmill training with conventional PT.	1	Lim et al. 2020
1b	Anti gravity treadmill may not have a difference in efficacy when compared to Conventional therapy for improving balance.	1	Duran et al. 2023
1b	Land-based and aquatic trunk exercises with conventional physiotherapy may produce greater improvements in balance than Conventional physiotherapy or 60min/d, 5d/wk, 4wks conventional physiotherapy.	1	Park et al. 2019b

3. Participation

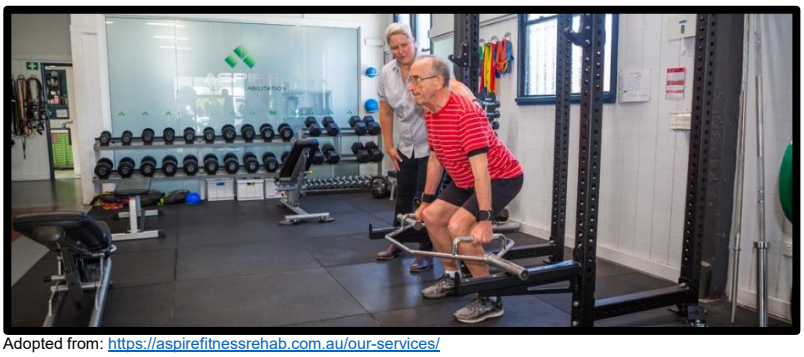
QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Aquatic Treadmill Walking or Aerobic Therapy may not have a difference in efficacy when compared to Overground or Treadmill Walking or Cycle Ergometer for improving quality of life.	1	Lee et al. 2018d
1b	Sequential Preparatory Approach Aquatic Therapy may produce greater improvements in quality of life than Aquatic Therapy.	1	Temperoni et al. 2020

Other Associated Outcome Measures

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Sequential Preparatory Approach Aquatic Therapy may produce greater improvements in upper extremity function than Aquatic Therapy.	1	Temperoni et al. 2020

Key Points

- Aquatic Therapy may be beneficial for improving motor recovery, neurophysiological measures, sensory and proprioceptive function, and activities of daily living, but not biomechanical balance measures, muscle strength, pain, gait speed, functional mobility, and balance, after stroke when compared to Conventional Therapy; the literature is mixed regarding biomechanical gait measures and gait endurance.
- Aquatic Therapy may be beneficial for improving aerobic measures and gait speed, but not balance, after stroke when compared to Land-Based Upper Extremity Exercises; the literature is mixed regarding muscle strength.
- Aquatic Treadmill Walking or Aerobic Therapy may not be beneficial for improving motor recovery, biomechanical gait measures, biomechanical balance measures, spasticity, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Overground or Treadmill Walking or Cycle Ergometer; the literature is mixed regarding muscle strength, range of motion, and neurophysiological measures.
- Aquatic Ai Chi Therapy with Dry Land Therapy may not be beneficial for improving pain after stroke when compared to Aquatic Ai Chi Therapy; the literature is mixed regarding biomechanical gait measures and functional mobility; Aquatic Ai Chi Therapy with Dry Land Therapy may result in lesser improvements in balance when compared to Aquatic Ai Chi Therapy.
- Dual-Task Aquatic Training may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility, and balance after stroke when compared to Neurodevelopmental Techniques or Land-Based Dual Motor Task.
- Aquatic Therapy with Strength Training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Aquatic Therapy.
- Sequential Preparatory Approach Aquatic Therapy may be beneficial for improving spasticity, balance, and quality of life, but not activities of daily living and functional mobility, after stroke when compared to Aquatic Therapy.
- Anti gravity treadmill may be beneficial for improving aerobic measures and gait endurance, but not activities of daily living and balance, after stroke when compared to Conventional therapy.
- Land-based and aquatic trunk exercises with conventional physiotherapy may be beneficial for improving activities of daily living and balance after stroke when compared to Conventional physiotherapy or 60min/d, 5d/wk, 4wks conventional physiotherapy.
- Aquatic Ai Chi therapy with Dry land therapy may be beneficial for improving functional mobility and pain, but not balance, after stroke when compared to Training on dry land.



- Aquatic Ai Chi therapy may be beneficial for improving balance and pain, but not functional mobility, after stroke when compared to Training on dry land.
- Waterjet resistance aquatic treadmill training with conventional PT may be beneficial for improving biomechanical gait measures, gait speed, and balance after stroke when compared to Ankle weight aquatic treadmill training with conventional PT.

Summary of Key Points: Aquatic Therapy

Intervention	Control(s)	Function domain(s)	Effect
Aquatic Therapy	Conventional Therapy	Motor recovery, neurophysiological measures, sensory and proprioceptive function, activities of daily living	+
Aquatic Therapy	Conventional Therapy	Biomechanical balance measures, muscle strength, pain, gait speed, functional mobility, balance	−
Aquatic Therapy	Conventional Therapy	Biomechanical gait measures, gait endurance	=
Aquatic Therapy	Land-Based Upper Extremity Exercises	Aerobic measures, gait speed	+
Aquatic Therapy	Land-Based Upper Extremity Exercises	Balance	−
Aquatic Therapy	Land-Based Upper Extremity Exercises	Muscle strength	=

Strength and Resistance Training

Adopted from: https://aspirefitnessrehab.com.au/our-services/

Gray et al. (2012) found that individuals experience decreases in muscle fibre length and lean muscle mass post stroke. Neural input to muscle groups are reduced, resulting in weakness and a decrease in muscle fibre length, which the fibres may adapt to if the muscle is not moved through the full range of motion (Gray et al., 2012). In contrast, Klein et al. (2013) did not find any significant differences in muscle volume or atrophy between the contralesional and ipsilesional limbs in relation to weakness. However, the authors reported lower levels of maximal voluntary contraction torque in the contralesional limb, which was associated with deficits in muscle activation and electromyographic amplitude.

Muscle strengthening as an intervention is designed to improve the force-generation capacity of hemiplegic limbs and enhance functional abilities. Conventional physiotherapy rehabilitation programs may not include muscle strengthening as there is a belief that strength training may increase spasticity (Miller & Light, 1997). While the effectiveness of strength training is difficult to assess due to variability in training programs, it has been suggested that strength training should be recommended as part of a stroke rehabilitation program (Ada et al., 2006).

Strength or resistance training can take various forms in which eccentric, isometric, or concentric exercises are performed. The muscle lengthens during contraction in eccentric training, stays constant during isometric training, and shortens during concentric training. Other forms of strength or resistance training can include the way in which the exercise is performed. For example, in the case of isokinetic strength training, the exercise machines used produce a constant pace of work or speed regardless of the effort expended. Alternatively, functional strength training involves performing functional exercises that mimic common real-life activities and that require the muscles

to work together. Progressive resistance training involves performing exercises in which additional load is continuously added to facilitate adaptation. Strength or resistance training can also be coupled with other forms of exercises such as aerobic training, can be administered in various settings, and also at various intensities.

A total of 53 RCTs were found that evaluated strength and resistance training for lower extremity motor rehabilitation. 26 RCTs compared Strength or Resistance Training with Conventional Therapy or Educational Classes (Cho et al. 2024; Shao et al. 2023; Lattouf et al. 2021; Patel et al. 2021a; Wu et al. 2020a; Gambassi et al. 2019; Hendrey et al. 2018; Knox et al. 2018; Fernandez-Gonzalo et al. 2016; Şen et al. 2015; Zou et al. 2015; Mares et al. 2014; Son et al. 2014; Lee et al. 2013c; Lee & Kang 2013b; Sekhar et al. 2013; Patil et al. 2011; Cooke et al. 2010; Sims et al. 2009; Bale et al. 2008; Flansbjer et al. 2008; Akbari & Karimi, 2006; Yang et al. 2006; Moreland et al. 2003; Kwakkel et al. 1999; Glasser 1986). Five RCTs compared Strength or Resistance Training with Stretching or Relaxation (Ivey et al. 2017; Moore et al. 2016; Mead et al. 2007; Ouellette et al. 2004; Kim et al. 2001). Six RCTs compared Aerobic and Resistance Training with Conventional Therapy or Aerobic Training (Lund et al. 2018; Marzolini et al. 2018; Lee et al. 2015d; Severinsen et al. 2014; Lee et al. 2008; Teixeira-Salmela et al. 1999). Four RCTs evaluated Strength and Resistance Training Modalities (Alabdulwahab et al. 2015; Chen et al. 2015a; Pandian et al. 2015; Clark & Patten 2013). Two RCTs evaluated Strength and Resistance Training Intensity (Ahmed et al. 2024; Lamberti et al. 2017). One RCT evaluated Strength Training Combined with Mirror Therapy (Simpson et al. 2019). One RCT compared Strength Training with Visual Feedback with Physical Therapy (Cho et al. 2021). Two RCTs compared Resistance Training with Balance Training with Conventional Therapy (Vahlberg et al. 2017a; Vahlberg et al. 2017b). One RCT compared Resistance Training with and without rTMS with Resistance Training or rTMS Alone (Cha et al. 2017c). One RCT compared Dietary Supplements with Resistance training with Resistance Training Alone (Yoshimura et al. 2019). One RCT compared Muscle Strength Training to Paralytic Muscles with Muscle Strength Training to Non-paralytic Muscles (Park et al. 2021a). One RCT compared Strength Training with Neurodevelopmental Techniques with Neurodevelopmental Techniques Alone (Ostrowska et al. 2022).

In addition, 22 RCTs in which strength and resistance training formed part of a combined or comparative intervention are cross-referenced at the end of Table 21; their primary listings appear in other tables.

The methodological details and results of all 53 RCTs are presented in Table 21.

Table 21. RCTs Evaluating Strength and Resistance Training for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Strength or Resistance Training vs Conventional Therapy or Educational Classes		
Cho et al. (2024) Feasibility/pilot RCT (4) Nstart=32 Nend=24 TPS=Chronic A + B vs A + C vs D	E1: Lower limb resistance training + Abdominal draw-in maneuver (ADIM) + Conventional tailored physical therapy, E2: lower limb exercise + ADIM + Conventional tailored physical therapy C: Conventional tailored physical therapy Duration: 30min/d, 3d/wk, 4wks	E1/E2 vs C: TIS (+exp1) PASS (+exp1) Modified Functional Reach Test (+exp1) BBS (+exp1) Foot print (+exp1) MBI (+exp1) E1 vs E2: TIS (+exp1) PASS (+exp1) Modified Functional Reach Test (+exp1) BBS (-) Foot print (+exp1) MBI (+exp1)
Shao et al. (2023) RCT (6) Nstart=139	E: Strength training + ADL C: Conventional rehab	E vs C: BBS(+exp) 6MWT(+exp)

Nend=127 TPS=Acute A + B vs 0	Duration: 240 mins/d (45 mins of strength/conventional training + 15 mins of bicycle dynamometer + 30 mins of hand function training + 30 mins of electrotherapy), 5dsw/k, 6wks	MBI(-) Peak torque(+exp)
Lattouf et al. (2021) RCT (5) Nstart=37 Nend=37 TPS=Chronic A vs B	E: Eccentric muscle strengthening + Standard rehabilitative care C: Standard rehabilitative care Duration: 60min/d, 5d/wk, for 4wks	E vs C: 10-Metre Walk Test (-) 6-Minute Walk Test (+exp) One-repetition maximum- paretic LE (+exp)
Patel et al. (2021a) RCT (6) Nstart=22 Nend=22 TPS=Chronic A vs B	E: Force-control training C: Ballistic ankle contraction strength training Duration: 90min/d, 2d/wk, for 2wks	E vs C: Post-hoc analysis (main effect) Stride variability stride length-paretic (-) stride length-nonparetic (-) stride length-mean both legs (-) stride time (-) Gait speed (-) Time * Training interaction Stride variability stride length-paretic (+exp) stride length-nonparetic (+exp) stride length-mean both legs (-) stride time (-) Gait speed (-) Ankle motor control accuracy: paretic (+exp) nonparetic (-) steadiness: paretic (-) nonparetic (+exp) Ankle strength paretic plantarflexion (+con) paretic dorsiflexion (-) nonparetic plantarflexion (+con) nonparetic dorsiflexion (-)
Wu et al. (2020a) RCT (7) Nstart=31 Nend=31 TPS=Acute A + B vs 0 Also in Table 10 (Physiotherapy and Exercise Programs)	E: Early conventional PT + intensive strength exercises C: Conventional physiotherapy Duration: 20-30min/d, 5d/wk conventional PT & 30min/d, 5d/wk, for 2wks strength exercises	E vs C: Fugl-Meyer Assessment (+exp) Functional Independence Measure - Ability to walk 50m (-) Berg Balance Scale (-) Barthel Index (-) Modified Rankin Scale (-)
Gambassi et al. (2019) RCT (6) Nstart=22 Nend=22 TPS=Chronic A vs 0	E: Resistance training + Conventional care (physical therapy) C: Conventional care (physical therapy) Duration: E: 2d/wk resistance training, 8wk + 2d/wk conventional care, for 8wks	E vs C: Isometric handgrip: paretic (-) non paretic (-) 10m Walk test (+exp) 5 repetition- Sit-to-Stand (+exp) Timed Up and Go (+exp) Hemodynamics: Systolic BP (-) Diastolic BP (-) Heart rate (+exp)

		Double product (+exp) Cardiac Autonomic Modulation: Time domain indexes (+exp) Nonlinear indexes (+exp) Oxidative stress markers (-)
Hendrey et al. (2018) RCT (8) Nstart=30 Nend=26 TPS=Subacute A vs 0	E: Ballistic Strength Training C: Conventional Therapy Duration: 45min/d, 3d/wk, for 6wks	E vs C: 10m Walk Test comfortable (+exp) fast (-) Timed Up and Go (-) Functional Ambulation category (no stats reported) Peak Jump height paretic (+exp) non paretic (-) Peak propulsive velocity paretic (+exp) non paretic (-) high level mobility assessment tool (no stats reported) Muscle torque non paretic hip flexors (-) paretic hip flexors (-) non paretic knee extensors (-) paretic knee extensors (-) non paretic knee flexors (-) paretic knee flexors (-) non paretic ankle plantar flexors (-) paretic ankle plantar flexors (-) non paretic ankle dorsiflexors (-) paretic ankle dorsiflexors (+exp) non paretic hip extensors prone knee straight (-) paretic hip extensors prone knee straight (-) non paretic hip extensors prone knee bent (-) paretic hip extensors prone knee bent (-) non paretic hip extensors supine (-) paretic hip extensors supine (-) Assessment of Quality of life 4D (no stats reported)
Knox et al. (2018) RCT (7) Nstart=144 Nend=128 TPS=Subacute A vs B vs C vs D	E1: Task oriented circuit gait training E2: Strength training of lower extremities C: Educational session on stroke management C: 90min/d, 1d Duration: E1/E2: 60min/d, 6d/12wk intervention sessions & C: 90min/d, 1d	E1/E2 vs C: Berg Balance Scale (+exp1) 10m walk Comfortable Gait Speed (+exp1) Fast gait speed (+exp1) Timed Up and Go test (+exp1) 6-minute walk test (+exp1, +exp2) E1 vs E2: Berg Balance Scale (+exp1) 10m walk Comfortable Gait Speed (+exp1) Fast gait speed (+exp1)

		Timed Up and Go test (+exp1) 6-minute walk test (+exp1)
Fernandez-Gonzalo et al. Teixeira-Salmela et al. (1999) RCT crossover (3) Nstart=13 Nend=13 TPS=Chronic A vs B	E: aerobic exercises and lower extremity muscle strengthening C: No intervention Duration: 60-90min/d, 3d/wk for 10wks	E vs C: Peak Isokinetic Torque of Muscle (Affected) (+exp) Pendulum Test (+exp) Nottingham Health Profile (+exp) Gait speed (+exp) Human Activity Profile (+exp) Stair Climbing (+exp)
Strength and Resistance Training Modalities		
Alabdulwahab et al. (2015) RCT (6) Nstart=26 Nend=23 TPS=Chronic A vs B	E: Functional task-oriented gait training with limb overloading C: Limb overloading resistance training Duration: 1hr/d, 3d/wk for 4wks	E vs C: Cadence (+exp1) Fast Gait Speed (+exp1) Slow Gait Speed (+exp1) Weight Bearing (+exp1) Stroke Impact Scale (+exp1)
Chen et al. (2015a) RCT (4) Nstart=31 Nend=24 TPS=Subacute A vs B	E: Isokinetic strengthening exercise C: Isometric strengthening exercise Duration: 3 sets/d, 5d/wk, for 4wks	E vs C: peak isometric torque of knees at 90° flexion sound side (-) flexion lesion side (-) extension sound side (-) extension lesion side (-) peak torque of isokinetic knee at angular velocities 60°/s extension lesion side (-) extension sound side (-) flexion lesion side (+exp) flexion sound side (-) peak torque of isokinetic knee at angular velocities 120°/s extension lesion side (-) extension sound side (-) flexion lesion side (+exp) flexion sound side (-) Short Form 36 (-) Timed Up and Go test (-) C-reactive protein (-) interleukin 6 (-) TNF-a (-)
Pandian et al. (2015) RCT (8) Nstart=35 Nend=35 TPS=Chronic A + B vs C	E: Motor therapy for Less Affected side (Progressive resistive and strengthening exercise + Bimanual-task training) C: neurophysiological-based conventional therapy Duration: 60min/d, 3d/wk for 8wks	E vs C: Affected side Brunnstrom Recovery Stage hand(+exp) arm (+exp) lower extremity (+exp) Fugl-Meyer Assessment upper extremity (+exp) upper arm(+exp) wrist & hand (-) lower extremity(+exp) Less-Affected side Minnesota Manual Dexterity Test(+exp) Purdue Peg Board Test(+exp) Manual Muscle Testing(+exp)

Clark & Patten (2013) RCT (6) Nstart=35 Nend=33 TPS=Chronic A vs B	E1: Eccentric resistance training + Gait training E2: Concentric resistance training + Gait training Duration: 90min/session, 3d/wk, for 5wks resistance training, then 90min/session, 3d/wk, for 3wks gait training.	E2 vs E1: Muscle power-paretic leg (+exp1) Walking speed (+exp1) neuromuscular activation (+exp1)
Strength and Resistance Training Intensity		
Ahmed et al. (2024) RCT (8) Nstart=32 Nend=30 TPS=Chronic A vs B	E: Low intensity resistance training with blood flow restriction (LIRT-BFR) C: High intensity resistance training (HIRT) Duration: 60min/d(40min resistance training, 10 min cycling, 10 mins treadmill), 3d/wk, 5wks	E vs C: 6MWT(-) FTSTST(-) TUG(-) BI(-) Cadence(-) Gait speed(-) Stride length(-) HADS(-)
Lamberti et al. (2017) RCT (7) Nstart=35 Nend=30 TPS=Chronic A1 vs A2	E1: Low intensity walking and resistance training program E2: High intensity walking and resistance training program Duration: 60min/d, 3d/wk, for 8wks	E1 vs E2: 6-minute walking distance test (+exp) SF-36 (+exp) peak power of the femoral quadriceps and biceps (+exp) 10-meter walk test (-) Berg balance scale (-) lower-limb strength (-) 5 sit-to-stand test (-)
Strength Training Combined with Mirror Therapy		
Simpson et al. (2019) RCT (7) Nstart=35 Nend=31 TPS=Chronic A + B vs A Also in Table 19 (Mirror Therapy); Table 24 (Home-Based and Caregiver-Mediated Exercise Programs)	E: Home-based isometric unilateral strength training + mirror therapy C: Home-based isometric unilateral strength training Duration: 20min/d, 3d/wk, for 4wks	E vs C: Trained ankle maximum voluntary contraction (-) Untrained ankle maximum voluntary contraction (-) 10-Metre Walk Test (-) Timed Up & Go Test (-) Modified Ashworth Scale (-) London Handicap Scale (-)
Strength Training with Visual Feedback vs Physical Therapy		
Cho et al. (2021) RCT (8) Nstart=25 Nend=23 TPS=Chronic A + B vs C Also in Table 15 (Biofeedback)	E: Bi-axial ankle-resistive strengthening muscle training + visual feedback C: Ankle Physical therapy Duration: 40min/d, 5d/wk, for 4wks	E vs C: Fugl-Meyer Assessment lower extremity score (+exp) Berg balance Scale (-) 10-meter walking test (-) Ankle co-contraction index Dorsiflexion (+exp) Plantarflexion (+exp) Inversion (+exp) Eversion (+exp) Ankle proprioception (-) Ankle co-activation index (+exp)

Resistance Training with Balance Training vs Conventional Therapy		
Vahlberg et al. (2017a) RCT (7) Nstart=43 Nend=43 TPS=Chronic A + B vs 0 Also in Table 11 (Balance Training)	E: Progressive resistance + balance training and motivational session C: Usual activity Duration: 75min/d, 2d/wk, for 12wks	E vs C: Bergs balance scale (-) body mass index (-) fat-free mass index (-) fat mass index (-) fat-mass percent (+exp) physical activity scale for the elderly (-) six-minute walking (+exp) short physical performance test (-) Chair rise 5times (-) Plasma albumin (-) Plasma total cholesterol (-) Plasma HDL and LDL cholesterol (-) Serum IGF-1 (+exp) Plasma CRP (-)
Vahlberg et al. (2017b) RCT (8) Nstart=67 Nend=57 TPS=Chronic A + B vs 0 Also in Table 11 (Balance Training)	E: Progressive resistance + balance training and motivational session C: Usual activity Duration: 75min/d, 2d/wk, for 12wks	E vs C: Berg Balance Scale (+exp) Short Physical Performance Battery (-) Six-Minute Walk Test (+exp) 10 Meter Walk Test (+exp) Euro-QoL-5D (-) Fall-Related Self-Efficacy Scale (-) Geriatric Depression Scale (-) Physical Activity Scale for the Elderly (-)
Resistance Training with and without rTMS vs Resistance Training or rTMS Alone		
Cha et al. (2017c) RCT (7) Nstart=30 Nend=30 TPS=Subacute A1 vs A2 vs B Also in Table 37 (Repetitive Transcranial Magnetic Stimulation (rTMS))	E1: Ankle Strengthening E2: Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation (rTMS) C: rTMS Duration: 10min/d, 5d/wk, for 8wks	E2 vs C: Motor evoked potential amplitude (+exp2) plantar flexor (+exp2) Dorsiflexor (+exp2) 10-Meter walk test (+exp2) E2 vs E1: Motor evoked potential amplitude (+exp2) Plantar flexor (+exp2) Dorsiflexor (+exp2) 10-Meter walk test (+exp2)
Dietary Supplements with Resistance training vs Resistance Training Alone		
Yoshimura et al. (2019) RCT (6) Nstart=49 Nend=44 TPS=Acute A + B vs B Also in Table 52 (Supplements and Vitamins)	E1: Leucine enriched amino acid + resistant training E2: resistant training Duration: 1 session/d leucine, vitamin, carbohydrate supplement, & ≤3 hr/d rehabilitation, for 8wks	E1 vs E2: Functional independence measure motor (+exp) cognitive (-) Skeletal muscle mass index (+exp) Handgrip strength (+exp) Mini Nutritional Assessment-Short Form (-) Protein Intake (-) Energy intake (-) Serum albumin (-)
Muscle Strength Training to Paralytic Muscles vs Muscle Strength Training to Non-paralytic Muscles		
Park et al. (2021a) RCT (6) Nstart=21	E: Muscle strengthening training to non-paralytic dorsiflexion muscles + neurodevelopmental therapy	E vs C: EMG Dorsiflexor Muscle Activity (-) Timed Up & Go Test (-)

Nend=21 TPS=Chronic A1 + B vs A2 + B Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)	C: Muscle strengthening training to paralytic dorsiflexion muscles + neurodevelopmental therapy Duration: 60min/d, 5d/wk, for 6wks neurodevelopmental therapy & 30min/d, 3d/wk, for 6wks muscle strengthening exercises	10-Metre Walk Test (-)
Strength Training with Neurodevelopmental Techniques vs Neurodevelopmental Techniques Alone		
Ostrowska et al. (2022) RCT (4) Nstart=131 Nend=120 TPS=Chronic A + B vs B	E: SPIDER support belt exercise device strengthening program + Neurophysiological methods C: Neurophysiological methods Duration: E: 45min/d 1d/wk SPIDER system + 45min, 4d/wk for 2wks neurophysiological training; C: 45min/d 5d/wk for 2wks	E vs C: Pelvic tilt(+exp) Center of mass(no stat)
Additional Comparisons from the Source Dataset		
Lee et al. (2013d) RCT (3) Nstart=39 Nend=39 TPS=Chronic A vs 0	E1: progressive resistive training with closed-kinetic chain E2: progressive resistive training with Open-kinetic chain C: No training Duration: 5x/wk for 6wks kinetic chain training	E1 vs E2 vs C: Contact area Forefoot (-) Midfoot (-) Hindfoot (+exp1) Peak contact force Forefoot (-) Midfoot (-) Hindfoot (+exp1) Contact impulse (-)
Page et al. (2008) RCT crossover (4) Nstart=7 Nend=7 TPS=Chronic A vs B	E: Resistance-based, reciprocal, affected leg locomotor training protocol using the NuStep apparatus C: Home exercise program Duration: 30min/d, 3d/wk, 8wks - 1wk washout	E vs C: Fugl-Meyer Assessment of lower extremity (No stats) Berg Balance Scale(No stats)
Carr et al. (2003) RCT (3) Nstart=40 Nend=40 TPS=Chronic A + B vs X	E: Aerobic training (upper and lower body ergometer) + strength training C: Aerobic training Duration: 20-40min 3d/wk, 16wks aerobic exercise & 8 activities/session, 3x/wk, 16wks strength exercise	E vs C: Peak VO2 max (not stats) Peak torque knee (not stats) shoulder (not stats) Total Cholesterol level (not stats), HDL level (not stats) FBS level (not stats)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Nadeem et al. (2024) RCT (7) Nstart=74 Nend=74 TPS=Chronic A vs 0 Primary listing: Table 4 (Trunk Training)	E: Core strengthening exercises + Conventional rehab C: Conventional rehab Duration: 45-50 min/d (15-20 min/session + 30 min rehab), 4d/wk, 8wks	E vs C: TIS (+exp) TUG (+exp)
Rana et al. (2024) RCT (6) Nstart=40	E: Metronome training + core strengthening + general balance exercises	E vs C: TUG (+exp) Tinetti Test (+exp)

Nend=40 TPS=Chronic A + B + C vs B + C Primary listing: Table 22 (Rhythmic Auditory Stimulation)	C: Core strengthening + general balance exercises Duration: 8wks	
Nakagawa et al. (2024) RCT (6) Nstart=60 Nend=60 TPS=Not reported A + B vs B Primary listing: Table 52 (Supplements and Vitamins)	E: 120g Nutritional supplement (Reha-Time Jelly BCAA enriched nutritional supplement) + resistance exercise training program C: Resistance training exercise program Duration: minimum 3d/wk, 12 wks (instructed to consume nutritional supplement within 1h of completing resistance exercise)	E vs C: 10mWT comfortable speed (-) maximum speed (-) 2min walking distance (-) 30s chair test (-) leg extensor torque paretic side (-) non-paretic side (-) FIM (-) motor (-) cognitive (-) blood pressure (-) serum levels/nutritional markers (-) BMI (-)
Hong et al. (2024) RCT (5) Nstart=60 Nend=60 TPS=Acute A + B vs B Primary listing: Table 53 (Acupuncture and Massage)	E: Acupuncture + trunk strengthening training + conventional rehab C: Conventional rehab + trunk strengthening training Duration: E: 75min/d (30 min acupuncture + 45 min rehab), 6d/wk, 8 wks; C: 45min/d, 6d/wk for 8wks	E vs C: holden walking scale (+exp) Berg Balance Scale (+exp) 10mWT step length (+exp) step width (+exp) gait speed (+exp)
Rizvi et al. (2023) RCT (7) Nstart=32 Nend=32 TPS=Subacute A vs B Primary listing: Table 10 (Physiotherapy and Exercise Programs)	E: Individualized cardio rehabilitation (aerobic & resistance training) + Conventional stroke rehab C: Conventional Stroke Rehabilitation Duration: 30-45min/d aerobic exercise, 4d/wk, +2d/wk body resistance training, for 12 wks	E vs C: BBS (-) TUG (+exp) mean NN (+exp) RMSSD (+exp) LF/HR ratio (-) SDNN (-) pNN50 (-) LF power (-) HF power (-) VLF power (-) total power (-) normalized LF (-) normalized HF (-) resting HR (+exp) peak HR (+exp) SBP (-) DBP (-) VE peak (+exp) RR peak (-) PETCOT2 rest (-) PETCO2 peak (+exp) VE/CO2 slope (+exp) VE/O2 slope (+exp) RER (+exp)

		workload (-) RPE (-) exercise duration (no stat)
Nindorera et al. (2023) RCT crossover (8) Nstart=46 Nend=46 TPS=Chronic A vs B Primary listing: Table 10 (Physiotherapy and Exercise Programs)	E: Circuit walking, balance, cycling and strength training (CBCS) C: Sociocultural intervention (board games, cultural discourse and drama) Duration: 120min/d, 3x/wk for 12wk	E vs C: ACTIVLIM Stroke Scale(+exp) Stroke Impairment Assessment Scale (SIAS) (+exp) Berg Balance Scale (BBS) (+exp) Hospital Anxiety and Depression Scale (HADS) (-) 6-Minute Walk Test (6MWT) (+exp) 10-Metre Walk Test (10MWT) (-) Participation Measurement Scale (PMscale) (+exp)
Zhu et al. (2023) RCT (6) Nstart=45 Nend=45 TPS=Chronic A vs B + C vs 0 Primary listing: Table 35 (Extracorporeal Shockwave Therapy and Therapeutic Ultrasound)	E1: Extracorpeal shockwave therapy E2: ESWT + Isokinetic strength training C: conventional rehab Duration: ESWT: 1d/wk, 4wks Strength training: 30min/d, 5d/wk, 4wks	E1 vs E2: MAS(-) EMG(+exp) rPT(-) E1 vs C: MAS(+exp) EMG(+exp) rPT(-) E2 vs C: MAS(+exp) EMG(-) rPT(-)
Midan et al. (2022) RCT (6) Nstart=30 Nend=30 TPS=Chronic A + B vs C Primary listing: Table 12 (Stretching or Mobilization Exercises)	E: Foot Mobilization + Intrinsic Foor Muscles Facilitation + (Strength and Resistance training including PNF, Gait training and Balance training through Pertubations) C: Strength and Resistance training including PNF, Gait training and Balance training through Pertubations Duration: 60 min/session, 3 session/wk, 4 wks	E vs C: Center of Pressure MediolaterI displacement (-) Mediolateral Speed (-) Mediolateral width (-) Anteroposterior speed (+exp) Anteroposterior displacement (+exp) Reverse Anteroposterior displacement (+exp)
Wang et al. (2022c) RCT (6) Nstart=21 Nend=19 TPS=Chronic A vs 0 Primary listing: Table 13 (Orthotic Devices)	E: Non-elastic taping + Exercise training (progressive resistance exercise, balance training and treadmill training) C: Sham taping + exercise training Duration: 50min/d, 2d/wk, for 6wks	E vs C: double support time (+exp) spatial symmetry index (-) temporal symmetry index (-) velocity (-) BBS (-) 6MWT (-) FES-I (-)
Antonio et al. (2022) RCT (8) Nstart=26 Nend=26 TPS=Chronic A vs B Primary listing: Table 16 (Dual-Task Training)	E: Dual Task (Consisting aerobic and resistance exercises while performing cognitive task) C: Aerobic and Resistance Exercises, without Performing Cognitive Task Duration: 60-90min, 2d/wk, for 15wks	E vs C: Timed-up-and-go Test (+exp) Cognitive Performance in TUG Dual Task (-) Dual Task Cost in in TUG (-) 10-M Walk Test (-) 10MWT Dual Task (-) Cognitive Performance in 10MWT Dual Task (-) Dual Task Cost in 10MWT (-)

Yang et al. (2006) RCT (7) Nstart=48 Nend=48 TPS=Chronic A vs 0 Primary listing: Table 5 (Task-Specific Training)	E: Task-oriented progressive resistance strength training C: No treatment Duration: 30min/d, 3d/wk for 4wks Task-oriented resistance training	E vs C: Muscle strength Hip flexor (+exp) Hip extensor (+exp) Knee flexor (+exp) Knee extensor (+exp) Ankle dorsiflexor (+exp) Ankle plantarflexor (+exp) 10-m Walk Velocity (+exp) Cadence (+exp) Stride length (+exp) 6-Minute Walk Test (+exp) Step Test (+exp) Timed Up-and-Go Test (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group
- indicates no statistically significant between groups differences at α=0.05
no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Strength or Resistance Training when compared to Conventional Therapy or Educational Classes for improving motor recovery.	3	Patel et al. 2021a; Wu et al. 2020a; Zou et al. 2015
1b	Strength and Resistance Training Modalities may produce greater improvements in motor recovery than Limb overloading resistance training.	1	Pandian et al. 2015
1b	Strength Training with Visual Feedback may produce greater improvements in motor recovery than Physical Therapy.	1	Cho et al. 2021
1b	Resistance Training with Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	1	Vahlberg et al. 2017a
2	Resistance-based, reciprocal, affected leg locomotor training protocol using the NuStep apparatus may not have a difference in efficacy when compared to Home exercise program for improving motor recovery.	1	Page et al. 2008
1b	Circuit walking, balance, cycling and strength training (CBCS) may produce greater improvements in motor recovery than Sociocultural intervention (board games, cultural discourse and drama).	1	Nindorera et al. 2023
1b	Early conventional physical therapy with intensive strength exercises may produce greater improvements in motor recovery than Conventional physiotherapy.	1	Wu et al. 2020a

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Strength or Resistance Training may produce greater improvements in biomechanical gait measures than Conventional Therapy or Educational Classes.	6	Patel et al. 2021a; Hendrey et al. 2018; Şen et al. 2015; Lee et al. 2013c; Cooke et al. 2010; Yang et al. 2006
1b	Strength and Resistance Training Modalities may produce greater improvements in biomechanical gait measures than Limb overloading resistance training.	1	Alabdulwahab et al. 2015
1b	Strength and Resistance Training Intensity may not have a difference in efficacy when compared to High intensity resistance training (HIRT) for improving biomechanical gait measures.	1	Ahmed et al. 2024
2	Strength Training with Neurodevelopmental Techniques may produce greater improvements in biomechanical gait measures than Neurodevelopmental Techniques Alone.	1	Ostrowska et al. 2022
2	Acupuncture with trunk strengthening training and conventional rehab may produce greater improvements in biomechanical gait measures than Conventional rehab with trunk strengthening training.	1	Hong et al. 2024
1b	Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not have a difference in efficacy when compared to Sham taping with exercise training for improving biomechanical gait measures.	1	Wang et al. 2022c

1b	Aquatic training with under water strength training may produce greater improvements in biomechanical gait measures than Aquatic training.	1	Gu et al. 2023
1b	Ankle strengthening training with brain-computer interface-based functional electrical stimulation on TA may not have a difference in efficacy when compared to Ankle strengthening training with functional electrical stimulation on TA for improving biomechanical gait measures.	1	Chung et al. 2020b
1b	Task-oriented progressive resistance strength training may produce greater improvements in biomechanical gait measures than No treatment.	1	Yang et al. 2006
2	There is conflicting evidence about the effect of Progressive resistive training with closed-kinetic chain when compared to Progressive resistive training with Open-kinetic chain or No training for improving biomechanical gait measures.	1	Lee et al. 2013d
2	Progressive resistive training with Open-kinetic chain may not have a difference in efficacy when compared to No training for improving biomechanical gait measures.	1	Lee et al. 2013d

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Strength or Resistance Training when compared to Conventional Therapy or Educational Classes for improving biomechanical balance measures.	2	Son et al. 2014; Bale et al. 2008
1b	Strength and Resistance Training Modalities may produce greater improvements in biomechanical balance measures than Limb overloading resistance training.	1	Alabdulwahab et al. 2015
1b	There is conflicting evidence about the effect of Foot Mobilization with Intrinsic Foor Muscles Facilitation and (Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations) when compared to Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations for improving biomechanical balance measures.	1	Midan et al. 2022

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Strength or Resistance Training may produce greater improvements in muscle strength than Conventional Therapy or Educational Classes.	13	Shao et al. 2023; Lattouf et al. 2021; Gambassi et al. 2019; Hendrey et al. 2018; Fernandez-Gonzalo et al. 2016; Zou et al. 2015; Lee & Kang 2013b; Sekhar et al. 2013; Cooke et al. 2010; Bale et al. 2008; Flansbjer et al. 2008; Akbari & Karimi 2006; Yang et al. 2006
1a	Strength or Resistance Training may produce greater improvements in muscle strength than Stretching or Relaxation.	3	Ivey et al. 2017; Ouellette et al. 2004; Kim et al. 2001
2	Aerobic and Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Aerobic Training for improving muscle strength.	3	Lund et al. 2018; Severinsen et al. 2014; Teixeira-Salmela et al. 1999
2	Aerobic training may result in lesser improvements in muscle strength when compared to Progressive resistance training.	1	Severinsen et al. 2014

2	Progressive resistance training may not have a difference in efficacy when compared to Resistance training of the arms (sham) for improving muscle strength.	1	Severinsen et al. 2014
1b	There is conflicting evidence about the effect of Strength and Resistance Training Modalities when compared to Limb overloading resistance training for improving muscle strength.	2	Chen et al. 2015a; Pandian et al. 2015
1b	Eccentric resistance training with Gait training may result in lesser improvements in muscle strength when compared to Concentric resistance training with Gait training.	1	Clark & Patten 2013
1b	Low intensity walking and resistance training program may not have a difference in efficacy when compared to High intensity walking and resistance training program for improving muscle strength.	1	Lamberti et al. 2017
1b	Home based Isometric Unilateral Strength Training with Mirror Therapy may not have a difference in efficacy when compared to Home based Isometric Unilateral Strength Training for improving muscle strength.	1	Simpson et al. 2019
1b	Strength Training with Visual Feedback may produce greater improvements in muscle strength than Physical Therapy.	1	Cho et al. 2021
1b	Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation may produce greater improvements in muscle strength than Ankle Strengthening.	1	Cha et al. 2017c
1b	Dietary Supplements with Resistance training may produce greater improvements in muscle strength than Resistance Training Alone.	1	Yoshimura et al. 2019
1b	120g Nutritional supplement (Reha-Time Jelly BCAA enriched nutritional supplement) with resistance exercise training program may not have a difference in efficacy when compared to Resistance training exercise program for improving muscle strength.	1	Nakagawa et al. 2024
1b	Dual Task (Consisting aerobic and resistance exercises while performing cognitive task) may not have a difference in efficacy when compared to Aerobic and Resistance Exercises, without Performing Cognitive Task for improving muscle strength.	1	Antonio et al. 2022
1b	Leucine enriched amino acid with resistant training may produce greater improvements in muscle strength than Resistant training.	1	Yoshimura et al. 2019
2	Aerobic training on cycle ergometer may not have a difference in efficacy when compared to Sham training of upper extremities for improving muscle strength.	1	Lund et al. 2018
1b	Aerobic cycling with progressive resistance training (PRT) may produce greater improvements in muscle strength than Sham cycling with Sham PRT.	1	Lee et al. 2008
1b	Task-oriented progressive resistance strength training may produce greater improvements in muscle strength than No treatment.	1	Yang et al. 2006

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Strength or Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Educational Classes for improving spasticity.	4	Fernandez-Gonzalo et al. 2016; Flansbjer et al. 2008; Akbari & Karimi 2006; Moreland et al. 2003
2	Aerobic and Resistance Training may produce greater improvements in spasticity than Conventional Therapy or Aerobic Training.	1	Teixeira-Salmela et al. 1999
1b	Home based Isometric Unilateral Strength Training with Mirror Therapy may not have a difference in efficacy when compared to	1	Simpson et al. 2019

	Home based Isometric Unilateral Strength Training for improving spasticity.		
1b	There is conflicting evidence about the effect of Extracorpeal shockwave therapy when compared to conventional rehab for improving spasticity.	1	Zhu et al. 2023
1b	Extracorpeal shockwave therapy may produce greater improvements in spasticity than extracorporeal shockwave therapy with Isokinetic strength training.	1	Zhu et al. 2023

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Strength or Resistance Training when compared to Conventional Therapy or Educational Classes for improving range of motion.	1	Patel et al. 2021a
1b	Aerobic and Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Aerobic Training for improving range of motion.	1	Marzolini et al. 2018
1b	Aerobic training (over ground walking) with Resistance training may not have a difference in efficacy when compared to Aerobic Training for improving range of motion.	1	Marzolini et al. 2018

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Strength or Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Educational Classes for improving neurophysiological measures.	1	Zou et al. 2015
1b	Aerobic and Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Aerobic Training for improving neurophysiological measures.	1	Marzolini et al. 2018
1b	Resistance Training with Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving neurophysiological measures.	1	Vahlberg et al. 2017a
1b	Resistance Training with and without repetitive transcranial magnetic stimulation may produce greater improvements in neurophysiological measures than Resistance Training or repetitive transcranial magnetic stimulation Alone.	1	Cha et al. 2017c
1b	Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation may produce greater improvements in neurophysiological measures than Ankle Strengthening.	1	Cha et al. 2017c
1b	Dietary Supplements with Resistance training may not have a difference in efficacy when compared to Resistance Training Alone for improving neurophysiological measures.	1	Yoshimura et al. 2019
1b	Muscle Strength Training to Paralytic Muscles may not have a difference in efficacy when compared to Muscle Strength Training to Non-paralytic Muscles for improving neurophysiological measures.	1	Park et al. 2021a
1b	120g Nutritional supplement (Reha-Time Jelly BCAA enriched nutritional supplement) with resistance exercise training program may not have a difference in efficacy when compared to Resistance training exercise program for improving neurophysiological measures.	1	Nakagawa et al. 2024

1b	There is conflicting evidence about the effect of Extracorpeal shockwave therapy when compared to conventional rehab for improving neurophysiological measures.	1	Zhu et al. 2023
1b	There is conflicting evidence about the effect of Extracorpeal shockwave therapy when compared to extracorporeal shockwave therapy with Isokinetic strength training for improving neurophysiological measures.	1	Zhu et al. 2023
1b	Leucine enriched amino acid with resistant training may not have a difference in efficacy when compared to Resistant training for improving neurophysiological measures.	1	Yoshimura et al. 2019
1b	Aerobic training (over ground walking) with Resistance training may not have a difference in efficacy when compared to Aerobic Training for improving neurophysiological measures.	1	Marzolini et al. 2018

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Strength or Resistance Training may produce greater improvements in aerobic measures than Conventional Therapy or Educational Classes.	1	Gambassi et al. 2019
1a	Strength or Resistance Training may produce greater improvements in aerobic measures than Stretching or Relaxation.	3	Ivey et al. 2017; Moore et al. 2016; Mead et al. 2007
1a	Aerobic and Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Aerobic Training for improving aerobic measures.	4	Lund et al. 2018; Marzolini et al. 2018; Lee et al. 2015d; Severinsen et al. 2014
2	Aerobic training may produce greater improvements in aerobic measures than Progressive resistance training.	1	Severinsen et al. 2014
2	Progressive resistance training may not have a difference in efficacy when compared to Resistance training of the arms (sham) for improving aerobic measures.	1	Severinsen et al. 2014
2	Aerobic training may produce greater improvements in aerobic measures than Resistance training of the arms (sham).	1	Severinsen et al. 2014
1b	120g Nutritional supplement (Reha-Time Jelly BCAA enriched nutritional supplement) with resistance exercise training program may not have a difference in efficacy when compared to Resistance training exercise program for improving aerobic measures.	1	Nakagawa et al. 2024
1b	Individualized cardio rehabilitation (aerobic & resistance training) with Conventional stroke rehab may not have a difference in efficacy when compared to Conventional Stroke Rehabilitation for improving aerobic measures.	1	Rizvi et al. 2023
2	Aerobic training on cycle ergometer may not have a difference in efficacy when compared to Sham training of upper extremities for improving aerobic measures.	1	Lund et al. 2018
1b	Aerobic training (over ground walking) with Resistance training may not have a difference in efficacy when compared to Aerobic Training for improving aerobic measures.	1	Marzolini et al. 2018
1b	There is conflicting evidence about the effect of Aerobic Training (fast walking and walking up-stairs) with Resistance Training when compared to Conventional care for improving aerobic measures.	1	Lee et al. 2015d
1b	There is conflicting evidence about the effect of Aerobic cycling with progressive resistance training (PRT) when compared to Sham cycling with Sham PRT for improving aerobic measures.	1	Lee et al. 2008

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Strength Training with Visual Feedback when compared to Physical Therapy for improving sensory and proprioceptive function.	1	Cho et al. 2021

PAIN			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Strength or Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Educational Classes for improving pain.	1	Fernandez-Gonzalo et al. 2016

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Strength or Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Educational Classes for improving activities of daily living.	5	Cho et al. 2024; Shao et al. 2023; Wu et al. 2020a; Şen et al. 2015; Kwakkel et al. 1999
2	Lower limb resistance training with Abdominal draw-in maneuver (abdominal drawing-in maneuver) and Conventional tailored physical therapy may produce greater improvements in activities of daily living than lower limb exercise with abdominal drawing-in maneuver and Conventional tailored physical therapy.	1	Cho et al. 2024
1b	Rehabilitation program with leg training may not have a difference in efficacy when compared to Rehabilitation program with Arm training for improving activities of daily living.	1	Kwakkel et al. 1999
1b	Rehabilitation program with leg training may produce greater improvements in activities of daily living than Rehabilitation program with arm & leg immobilized.	1	Kwakkel et al. 1999
1b	Rehabilitation program with Arm training may not have a difference in efficacy when compared to Rehabilitation program with arm & leg immobilized for improving activities of daily living.	1	Kwakkel et al. 1999
1b	Strength or Resistance Training may not have a difference in efficacy when compared to Stretching or Relaxation for improving activities of daily living.	1	Mead et al. 2007
2	Aerobic and Resistance Training may produce greater improvements in activities of daily living than Conventional Therapy or Aerobic Training.	1	Teixeira-Salmela et al. 1999
1b	Strength and Resistance Training Intensity may not have a difference in efficacy when compared to High intensity resistance training (HIRT) for improving activities of daily living.	1	Ahmed et al. 2024
1a	Resistance Training with Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	2	Vahlberg et al. 2017a; Vahlberg et al. 2017b
1b	There is conflicting evidence about the effect of Dietary Supplements with Resistance training when compared to Resistance Training Alone for improving activities of daily living.	1	Yoshimura et al. 2019
1b	120g Nutritional supplement (Reha-Time Jelly BCAA enriched nutritional supplement) with resistance exercise training program may not have a difference in efficacy when compared to Resistance training exercise program for improving activities of daily living.	1	Nakagawa et al. 2024

1b	Early conventional physical therapy with intensive strength exercises may not have a difference in efficacy when compared to Conventional physiotherapy for improving activities of daily living.	1	Wu et al. 2020a
1b	There is conflicting evidence about the effect of Leucine enriched amino acid with resistant training when compared to Resistant training for improving activities of daily living.	1	Yoshimura et al. 2019

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Strength or Resistance Training may produce greater improvements in gait speed than Conventional Therapy or Educational Classes.	13	Lattouf et al. 2021; Patel et al. 2021a; Gambassi et al. 2019; Hendrey et al. 2018; Knox et al. 2018; Şen et al. 2015; Lee et al. 2013c; Lee & Kang 2013b; Cooke et al. 2010; Bale et al. 2008; Flansbjer et al. 2008; Yang et al. 2006; Kwakkel et al. 1999
1b	Task oriented circuit gait training may produce greater improvements in gait speed than Strength training of lower extremities.	1	Knox et al. 2018
1b	Rehabilitation program with leg training may not have a difference in efficacy when compared to Rehabilitation program with Arm training for improving gait speed.	1	Kwakkel et al. 1999
1b	Rehabilitation program with leg training may produce greater improvements in gait speed than Rehabilitation program with arm & leg immobilized.	1	Kwakkel et al. 1999
1b	Rehabilitation program with Arm training may not have a difference in efficacy when compared to Rehabilitation program with arm & leg immobilized for improving gait speed.	1	Kwakkel et al. 1999
1a	Strength or Resistance Training may not have a difference in efficacy when compared to Stretching or Relaxation for improving gait speed.	5	Ivey et al. 2017; Moore et al. 2016; Mead et al. 2007; Ouellette et al. 2004; Kim et al. 2001

1b	Task oriented circuit gait training may produce greater improvements in balance than Educational session on stroke management.	1	Knox et al. 2018
2	Aerobic training on cycle ergometer may not have a difference in efficacy when compared to Sham training of upper extremities for improving balance.	1	Lund et al. 2018
1b	Aerobic Training (fast walking and walking up-stairs) with Resistance Training may not have a difference in efficacy when compared to Conventional care for improving balance.	1	Lee et al. 2015d
2	Task Oriented circuit LE strength training with physiotherapy may produce greater improvements in balance than Conventional physiotherapy.	1	Indurkar et al. 2013

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Resistance Training with Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving falls and fear of falling.	1	Vahlberg et al. 2017b
1b	Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not have a difference in efficacy when compared to Sham taping with exercise training for improving falls and fear of falling.	1	Wang et al. 2022c
1b	Dual Task (Consisting aerobic and resistance exercises while performing cognitive task) may not have a difference in efficacy when compared to Aerobic and Resistance Exercises, without Performing Cognitive Task for improving falls and fear of falling.	1	Antonio et al. 2022

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Strength or Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Educational Classes for improving quality of life.	4	Fernandez-Gonzalo et al. 2016; Şen et al. 2015; Sims et al. 2009; Flansbjer et al. 2008

1a	Strength or Resistance Training may not have a difference in efficacy when compared to Stretching or Relaxation for improving quality of life.	3	Mead et al. 2007; Ouellette et al. 2004; Kim et al. 2001
2	Aerobic and Resistance Training may produce greater improvements in quality of life than Conventional Therapy or Aerobic Training.	1	Teixeira-Salmela et al. 1999
1b	Strength and Resistance Training Modalities may produce greater improvements in quality of life than Limb overloading resistance training.	1	Alabdulwahab et al. 2015
1b	Low intensity walking and resistance training program may produce greater improvements in quality of life than High intensity walking and resistance training program.	1	Lamberti et al. 2017
1b	Home based Isometric Unilateral Strength Training with Mirror Therapy may not have a difference in efficacy when compared to Home based Isometric Unilateral Strength Training for improving quality of life.	1	Simpson et al. 2019
1b	Resistance Training with Balance Training may not have a difference in efficacy when compared to Conventional Therapy for improving quality of life.	1	Vahlberg et al. 2017b
1b	Circuit walking, balance, cycling and strength training (CBCS) may produce greater improvements in quality of life than Sociocultural intervention (board games, cultural discourse and drama).	1	Nindorera et al. 2023
1b	Dual Task (Consisting aerobic and resistance exercises while performing cognitive task) may not have a difference in efficacy when compared to Aerobic and Resistance Exercises, without Performing Cognitive Task for improving quality of life.	1	Antonio et al. 2022
2	Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not have a difference in efficacy when compared to Sham Combined aerobic and resistance training with Sham Cognitive training for improving quality of life.	1	Koch et al. 2020
1b	There is conflicting evidence about the effect of Aerobic cycling with progressive resistance training (PRT) when compared to Sham cycling with Sham PRT for improving quality of life.	1	Lee et al. 2008
2	Aerobic training may not have a difference in efficacy when compared to Progressive resistance training for improving quality of life.	1	Severinsen et al. 2014
2	Aerobic training or Progressive resistance training may not have a difference in efficacy when compared to Resistance training of the arms (sham) for improving quality of life.	1	Severinsen et al. 2014

Other Associated Outcome Measures

MOOD			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Strength or Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Educational Classes for improving mood.	1	Sims et al. 2009
1b	Strength or Resistance Training may not have a difference in efficacy when compared to Stretching or Relaxation for improving mood.	1	Mead et al. 2007
1b	Strength and Resistance Training Intensity may not have a difference in efficacy when compared to High intensity resistance training (HIRT) for improving mood.	1	Ahmed et al. 2024

1b	Circuit walking, balance, cycling and strength training (CBCS) may not have a difference in efficacy when compared to Sociocultural intervention (board games, cultural discourse and drama) for improving mood.	1	Nindorera et al. 2023

COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Strength or Resistance Training may not have a difference in efficacy when compared to Conventional Therapy or Educational Classes for improving cognition.	2	Fernandez-Gonzalo et al. 2016; Sims et al. 2009
1b	Dual Task (Consisting aerobic and resistance exercises while performing cognitive task) may not have a difference in efficacy when compared to Aerobic and Resistance Exercises, without Performing Cognitive Task for improving cognition.	1	Antonio et al. 2022
2	Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not have a difference in efficacy when compared to Sham Combined aerobic and resistance training with Sham Cognitive training for improving cognition.	1	Koch et al. 2020

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Functional strength training - upper limb may produce greater improvements in upper extremity function than Functional strength training - lower limb.	1	Mares et al. 2014
1b	Rehabilitation program with leg training may not have a difference in efficacy when compared to Rehabilitation program with Arm training for improving upper extremity function.	1	Kwakkel et al. 1999
1b	Rehabilitation program with leg training or Rehabilitation program with Arm training may produce greater improvements in upper extremity function than Rehabilitation program with arm & leg immobilized.	1	Kwakkel et al. 1999
1b	Strength or Resistance Training may not have a difference in efficacy when compared to Stretching or Relaxation for improving upper extremity function.	1	Ouellette et al. 2004
1a	Aerobic and Resistance Training may produce greater improvements in upper extremity function than Conventional Therapy or Aerobic Training.	2	Marzolini et al. 2018; Lee et al. 2015d
1b	Strength and Resistance Training Modalities may produce greater improvements in upper extremity function than Limb overloading resistance training.	1	Pandian et al. 2015
1b	Dietary Supplements with Resistance training may not have a difference in efficacy when compared to Resistance Training Alone for improving upper extremity function.	1	Yoshimura et al. 2019
2	Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not have a difference in efficacy when compared to Sham Combined aerobic and resistance training with Sham Cognitive training for improving upper extremity function.	1	Koch et al. 2020
1b	Leucine enriched amino acid with resistant training may not have a difference in efficacy when compared to Resistant training for improving upper extremity function.	1	Yoshimura et al. 2019

1b	Aerobic training (over ground walking) with Resistance training may produce greater improvements in upper extremity function than Aerobic Training.	1	Marzolini et al. 2018
1b	Aerobic Training (fast walking and walking up-stairs) with Resistance Training may produce greater improvements in upper extremity function than Conventional care.	1	Lee et al. 2015d

Key Points

- Strength or Resistance Training may be beneficial for improving biomechanical gait measures, muscle strength, aerobic measures, gait speed, functional mobility, and balance, but not spasticity, neurophysiological measures, pain, activities of daily living, gait endurance, and quality of life, after stroke when compared to Conventional Therapy or Educational Classes; the literature is mixed regarding motor recovery, biomechanical balance measures, and range of motion.
- Lower limb resistance training with Abdominal draw-in maneuver (abdominal drawing-in maneuver) and Conventional tailored physical therapy may be beneficial for improving activities of daily living and balance after stroke when compared to lower limb exercise with abdominal drawing-in maneuver and Conventional tailored physical therapy.
- Task oriented circuit gait training may be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Strength training of lower extremities.
- Functional strength training - upper limb may not be beneficial for improving functional mobility after stroke when compared to Functional strength training - lower limb.
- Rehabilitation program with leg training may not be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Rehabilitation program with Arm training.
- Strength or Resistance Training may be beneficial for improving muscle strength, aerobic measures, and gait endurance, but not activities of daily living, gait speed, functional mobility, and quality of life, after stroke when compared to Stretching or Relaxation; the literature is mixed regarding balance.
- Aerobic and Resistance Training may be beneficial for improving spasticity, activities of daily living, gait speed, and quality of life, but not muscle strength, range of motion, neurophysiological measures, aerobic measures, gait endurance, functional mobility, and balance, after stroke when compared to Conventional Therapy or Aerobic Training.
- Aerobic training may be beneficial for improving aerobic measures, but not gait speed, gait endurance, and quality of life, after stroke when compared to Progressive resistance training; Aerobic training may result in lesser improvements in muscle strength when compared to Progressive resistance training.
- Sham progressive resistance training with Cycling may be beneficial for improving gait endurance after stroke when compared to Sham progressive resistance training with Sham cycling.
- Strength and Resistance Training Modalities may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, quality of life, and motor recovery, but not functional mobility, after stroke when compared to Limb overloading resistance training; the literature is mixed regarding muscle strength.
- Eccentric resistance training with Gait training may result in lesser improvements in muscle strength and gait speed when compared to Concentric resistance training with Gait training.
- Strength and Resistance Training Intensity may not be beneficial for improving biomechanical gait measures, activities of daily living, gait speed, gait endurance, and functional mobility after stroke when compared to High intensity resistance training (HIRT).
- Low intensity walking and resistance training program may be beneficial for improving gait endurance and quality of life, but not muscle strength, gait speed, functional mobility, and balance, after stroke when compared to High intensity walking and resistance training program.
- Home based Isometric Unilateral Strength Training with Mirror Therapy may not be beneficial for improving muscle strength, spasticity, gait speed, functional mobility, and quality of life after stroke when compared to Home based Isometric Unilateral Strength Training.
- Strength Training with Visual Feedback may be beneficial for improving motor recovery and muscle strength, but not gait speed and balance, after stroke when compared to Physical Therapy; the literature is mixed regarding sensory and proprioceptive function.

- Resistance Training with Balance Training may be beneficial for improving gait speed and gait endurance, but not motor recovery, neurophysiological measures, activities of daily living, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy; the literature is mixed regarding balance.
- Resistance Training with and without repetitive transcranial magnetic stimulation may be beneficial for improving neurophysiological measures and gait speed after stroke when compared to Resistance Training or repetitive transcranial magnetic stimulation Alone.
- Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation may be beneficial for improving muscle strength, neurophysiological measures, and gait speed after stroke when compared to Ankle Strengthening.
- Dietary Supplements with Resistance training may be beneficial for improving muscle strength, but not neurophysiological measures, after stroke when compared to Resistance Training Alone; the literature is mixed regarding activities of daily living.
- Muscle Strength Training to Paralytic Muscles may not be beneficial for improving neurophysiological measures, gait speed, and functional mobility after stroke when compared to Muscle Strength Training to Non-paralytic Muscles.
- Strength Training with Neurodevelopmental Techniques may be beneficial for improving biomechanical gait measures after stroke when compared to Neurodevelopmental Techniques Alone.
- Resistance-based, reciprocal, affected leg locomotor training protocol using the NuStep apparatus may not be beneficial for improving motor recovery and balance after stroke when compared to Home exercise program.
- Core strengthening exercises with Conventional rehab may be beneficial for improving functional mobility and balance after stroke when compared to Conventional rehab.
- Metronome training with core strengthening and general balance exercises may be beneficial for improving functional mobility after stroke when compared to Core strengthening with general balance exercises.
- 120g Nutritional supplement (Reha-Time Jelly BCAA enriched nutritional supplement) with resistance exercise training program may not be beneficial for improving muscle strength, neurophysiological measures, aerobic measures, activities of daily living, gait speed, and gait endurance after stroke when compared to Resistance training exercise program.
- Acupuncture with trunk strengthening training and conventional rehab may be beneficial for improving biomechanical gait measures, gait speed, functional mobility, and balance after stroke when compared to Conventional rehab with trunk strengthening training.
- Individualized cardio rehabilitation (aerobic & resistance training) with Conventional stroke rehab may not be beneficial for improving aerobic measures, functional mobility, and balance after stroke when compared to Conventional Stroke Rehabilitation.
- Circuit walking, balance, cycling and strength training (CBCS) may be beneficial for improving motor recovery, gait endurance, balance, and quality of life, but not gait speed, after stroke when compared to Sociocultural intervention (board games, cultural discourse and drama).
- The literature is mixed regarding the effect of Extracorpeal shockwave therapy on spasticity and neurophysiological measures after stroke when compared to conventional rehab.
- Extracorpeal shockwave therapy may be beneficial for improving spasticity after stroke when compared to extracorporeal shockwave therapy with Isokinetic strength training; the literature is mixed regarding neurophysiological measures.
- The literature is mixed regarding the effect of Foot Mobilization with Intrinsic Foor Muscles Facilitation and (Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations) on biomechanical balance measures after stroke when compared to Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations.
- Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, balance, and falls and fear of falling after stroke when compared to Sham taping with exercise training.
- Dual Task (Consisting aerobic and resistance exercises while performing cognitive task) may not be beneficial for improving muscle strength, gait speed, gait endurance, functional mobility, balance, falls

and fear of falling, and quality of life after stroke when compared to Aerobic and Resistance Exercises, without Performing Cognitive Task.

- Aquatic training with under water strength training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Aquatic training.
- Early conventional physical therapy with intensive strength exercises may be beneficial for improving motor recovery, but not activities of daily living and balance, after stroke when compared to Conventional physiotherapy.
- Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not be beneficial for improving gait speed, gait endurance, functional mobility, and quality of life after stroke when compared to Sham Combined aerobic and resistance training with Sham Cognitive training.
- Ankle strengthening training with brain-computer interface-based functional electrical stimulation on TA may be beneficial for improving gait speed, but not biomechanical gait measures and balance, after stroke when compared to Ankle strengthening training with functional electrical stimulation on TA.
- Leucine enriched amino acid with resistant training may be beneficial for improving muscle strength, but not neurophysiological measures, after stroke when compared to Resistant training; the literature is mixed regarding activities of daily living.
- Task oriented circuit gait training may be beneficial for improving gait speed, functional mobility, balance, and gait endurance after stroke when compared to Educational session on stroke management.
- Aerobic training on cycle ergometer may not be beneficial for improving muscle strength, aerobic measures, gait speed, gait endurance, and balance after stroke when compared to Sham training of upper extremities.
- Aerobic training (over ground walking) with Resistance training may not be beneficial for improving range of motion, neurophysiological measures, aerobic measures, gait endurance, and functional mobility after stroke when compared to Aerobic Training.
- Aerobic Training (fast walking and walking up-stairs) with Resistance Training may be beneficial for improving gait speed, gait endurance, and functional mobility, but not balance, after stroke when compared to Conventional care; the literature is mixed regarding aerobic measures.
- Task Oriented circuit LE strength training with physiotherapy may be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Conventional physiotherapy.
- Aerobic cycling with progressive resistance training (PRT) may be beneficial for improving muscle strength after stroke when compared to Sham cycling with Sham PRT; the literature is mixed regarding gait speed, aerobic measures, gait endurance, quality of life, and functional mobility.
- Task-oriented progressive resistance strength training may be beneficial for improving biomechanical gait measures, muscle strength, gait speed, gait endurance, and functional mobility after stroke when compared to No treatment.
- Strength training of lower extremities may be beneficial for improving gait endurance after stroke when compared to Educational session on stroke management.
- Rehabilitation program with leg training may be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Rehabilitation program with arm & leg immobilized.
- Rehabilitation program with Arm training may not be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Rehabilitation program with arm & leg immobilized.
- Progressive resistance training may not be beneficial for improving muscle strength, aerobic measures, gait speed, gait endurance, and quality of life after stroke when compared to Resistance training of the arms (sham).
- Aerobic training may be beneficial for improving aerobic measures, but not gait speed, gait endurance, and quality of life, after stroke when compared to Resistance training of the arms (sham).
- Progressive resistive training with Open-kinetic chain may not be beneficial for improving biomechanical gait measures after stroke when compared to No training.

- The literature is mixed regarding the effect of Progressive resistive training with closed-kinetic chain on biomechanical gait measures after stroke when compared to Progressive resistive training with Open-kinetic chain or No training.

Summary of Key Points: Strength and Resistance Training

Intervention	Control(s)	Function domain(s)	Effect
Strength or Resistance Training	Conventional Therapy or Educational Classes	Biomechanical gait measures, muscle strength, aerobic measures, gait speed, functional mobility, balance	+
Strength or Resistance Training	Conventional Therapy or Educational Classes	Spasticity, neurophysiological measures, pain, activities of daily living, gait endurance, quality of life	–
Strength or Resistance Training	Conventional Therapy or Educational Classes	Motor recovery, biomechanical balance measures, range of motion	=
Lower limb resistance training with Abdominal draw-in maneuver (abdominal drawing-in maneuver) and Conventional tailored physical therapy	lower limb exercise with abdominal drawing-in maneuver and Conventional tailored physical therapy	Activities of daily living, balance	+
Task oriented circuit gait training	Strength training of lower extremities	Gait speed, gait endurance, functional mobility, balance	+
Functional strength training - upper limb	Functional strength training - lower limb	Functional mobility	–
Rehabilitation program with leg training	Rehabilitation program with Arm training	Activities of daily living, gait speed, functional mobility	–
Strength or Resistance Training	Stretching or Relaxation	Muscle strength, aerobic measures, gait endurance	+
Strength or Resistance Training	Stretching or Relaxation	Activities of daily living, gait speed, functional mobility, quality of life	–
Strength or Resistance Training	Stretching or Relaxation	Balance	=
Aerobic and Resistance Training	Conventional Therapy or Aerobic Training	Spasticity, activities of daily living, gait speed, quality of life	+
Aerobic and Resistance Training	Conventional Therapy or Aerobic Training	Muscle strength, range of motion, neurophysiological measures, aerobic measures, gait endurance, functional mobility, balance	–
Aerobic training	Progressive resistance training	Aerobic measures	+
Aerobic training	Progressive resistance training	Muscle strength, gait speed, gait endurance, quality of life	–
Sham progressive resistance training with Cycling	Sham progressive resistance training with Sham cycling	Gait endurance	+
Strength and Resistance Training Modalities	Limb overloading resistance training	Biomechanical gait measures, biomechanical balance measures, gait speed, quality of life, motor recovery	+
Strength and Resistance Training Modalities	Limb overloading resistance training	Functional mobility	–
Strength and Resistance Training Modalities	Limb overloading resistance training	Motor recovery	+
Eccentric resistance training with Gait training	Concentric resistance training with Gait training	Muscle strength, gait speed	–

Strength and Resistance Training Intensity	High intensity resistance training (HIRT)	Biomechanical gait measures, activities of daily living, gait speed, gait endurance, functional mobility	−
Low intensity walking and resistance training program	High intensity walking and resistance training program	Gait endurance, quality of life	+
Low intensity walking and resistance training program	High intensity walking and resistance training program	Muscle strength, gait speed, functional mobility, balance	−
Home based Isometric Unilateral Strength Training with Mirror Therapy	Home based Isometric Unilateral Strength Training	Muscle strength, spasticity, gait speed, functional mobility, quality of life	−
Strength Training with Visual Feedback	Physical Therapy	Motor recovery, muscle strength	+
Strength Training with Visual Feedback	Physical Therapy	Gait speed, balance	−
Strength Training with Visual Feedback	Physical Therapy	Sensory and proprioceptive function	=
Resistance Training with Balance Training	Conventional Therapy	Gait speed, gait endurance	+
Resistance Training with Balance Training	Conventional Therapy	Motor recovery, neurophysiological measures, activities of daily living, functional mobility, falls and fear of falling, quality of life	−
Resistance Training with Balance Training	Conventional Therapy	Balance	=
Resistance Training with and without repetitive transcranial magnetic stimulation	Resistance Training or repetitive transcranial magnetic stimulation Alone	Neurophysiological measures, gait speed	+
Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation	Ankle Strengthening	Muscle strength, neurophysiological measures, gait speed	+
Dietary Supplements with Resistance training	Resistance Training Alone	Muscle strength	+
Dietary Supplements with Resistance training	Resistance Training Alone	Neurophysiological measures	−
Dietary Supplements with Resistance training	Resistance Training Alone	Activities of daily living	=
Muscle Strength Training to Paralytic Muscles	Muscle Strength Training to Non-paralytic Muscles	Neurophysiological measures, gait speed, functional mobility	−
Strength Training with Neurodevelopmental Techniques	Neurodevelopmental Techniques Alone	Biomechanical gait measures	+
Resistance-based, reciprocal, affected leg locomotor training protocol using the NuStep apparatus	Home exercise program	Motor recovery, balance	−
Core strengthening exercises with Conventional rehab	Conventional rehab	Functional mobility, balance	+
Metronome training with core strengthening and general balance exercises	Core strengthening with general balance exercises	Functional mobility	+
120g Nutritional supplement (Reha-Time Jelly BCAA enriched nutritional supplement) with resistance exercise training program	Resistance training exercise program	Muscle strength, neurophysiological measures, aerobic measures, activities of daily living, gait speed, gait endurance	−

Acupuncture with trunk strengthening training and conventional rehab	Conventional rehab with trunk strengthening training	Biomechanical gait measures, gait speed, functional mobility, balance	+
Individualized cardio rehabilitation (aerobic & resistance training) with Conventional stroke rehab	Conventional Stroke Rehabilitation	Aerobic measures, functional mobility, balance	–
Circuit walking, balance, cycling and strength training (CBCS)	Sociocultural intervention (board games, cultural discourse and drama)	Motor recovery, gait endurance, balance, quality of life	+
Circuit walking, balance, cycling and strength training (CBCS)	Sociocultural intervention (board games, cultural discourse and drama)	Gait speed	–
Extracorpeal shockwave therapy	conventional rehab	Neurophysiological measures, spasticity	=
Extracorpeal shockwave therapy	extracorporeal shockwave therapy with Isokinetic strength training	Spasticity	+
Extracorpeal shockwave therapy	extracorporeal shockwave therapy with Isokinetic strength training	Neurophysiological measures	=
Foot Mobilization with Intrinsic Foor Muscles Facilitation and (Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations)	Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations	Biomechanical balance measures	=
Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training)	Sham taping with exercise training	Biomechanical gait measures, gait speed, gait endurance, balance, falls and fear of falling	–
Dual Task (Consisting aerobic and resistance exercises while performing cognitive task)	Aerobic and Resistance Exercises, without Performing Cognitive Task	Muscle strength, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Aquatic training with under water strength training	Aquatic training	Biomechanical gait measures, gait speed, gait endurance, functional mobility, balance	+
Early conventional physical therapy with intensive strength exercises	Conventional physiotherapy	Motor recovery	+
Early conventional physical therapy with intensive strength exercises	Conventional physiotherapy	Activities of daily living, balance	–
Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training	Sham Combined aerobic and resistance training with Sham Cognitive training	Gait speed, gait endurance, functional mobility, quality of life	–
Ankle strengthening training with brain-computer interface-based functional electrical stimulation on TA	Ankle strengthening training with functional electrical stimulation on TA	Gait speed	+
Ankle strengthening training with brain-computer interface-based functional electrical stimulation on TA	Ankle strengthening training with functional electrical stimulation on TA	Biomechanical gait measures, balance	–
Task oriented circuit gait training	Educational session on stroke management	Gait speed, functional mobility, balance, gait endurance	+
Aerobic training on cycle ergometer	Sham training of upper extremities	Muscle strength, aerobic measures, gait speed, gait endurance, balance	–

Aerobic training (over ground walking) with Resistance training	Aerobic Training	Range of motion, neurophysiological measures, aerobic measures, gait endurance, functional mobility	−
Aerobic Training (fast walking and walking up-stairs) with Resistance Training	Conventional care	Gait speed, gait endurance, functional mobility	+
Aerobic Training (fast walking and walking up-stairs) with Resistance Training	Conventional care	Balance	−
Aerobic Training (fast walking and walking up-stairs) with Resistance Training	Conventional care	Aerobic measures	=
Task Oriented circuit LE strength training with physiotherapy	Conventional physiotherapy	Gait speed, gait endurance, functional mobility, balance	+
Aerobic cycling with progressive resistance training (PRT)	Sham cycling with Sham PRT	Muscle strength	+
Aerobic cycling with progressive resistance training (PRT)	Sham cycling with Sham PRT	Aerobic measures, gait endurance, quality of life, gait speed, functional mobility	=
Aerobic cycling with progressive resistance training (PRT)	Sham cycling with Sham PRT	Aerobic measures, gait speed, functional mobility	=
Task-oriented progressive resistance strength training	No treatment	Biomechanical gait measures, muscle strength, gait speed, gait endurance, functional mobility	+
Strength training of lower extremities	Educational session on stroke management	Gait endurance	+
Rehabilitation program with leg training	Rehabilitation program with arm & leg immobilized	Activities of daily living, gait speed, functional mobility	+
Rehabilitation program with Arm training	Rehabilitation program with arm & leg immobilized	Activities of daily living, gait speed, functional mobility	−
Progressive resistance training	Resistance training of the arms (sham)	Muscle strength, aerobic measures, gait speed, gait endurance, quality of life	−
Leucine enriched amino acid with resistant training	Resistant training	Muscle strength	+
Leucine enriched amino acid with resistant training	Resistant training	Neurophysiological measures	−
Leucine enriched amino acid with resistant training	Resistant training	Activities of daily living	=

Rhythmic Auditory Stimulation

Adopted from: https://unsplash.com/
Adapted from: https://www.sciencedirect.com/science/article/abs/pii/S2211285518302337

Rhythmic auditory stimulation (RAS) is a form of gait training that involves the sensory cueing of motor systems. The rhythmic auditory stimulus provides a time reference for motor gait response, such that the gait response and auditory stimulus develop into a stable temporal relationship (Thaut et al. 1997). This is possible due to the strong connection between auditory and motor systems across cortical, subcortical and spinal levels.

RAS can be implemented through use of metronomes or music cues that set a tempo to which a patient follows during a training session. Various mechanisms have been proposed to explain how rhythm may influence motor rehabilitation, including through accelerating motor learning, providing a different type of motor learning process, acquiring or refining temporal skills, and lastly through improving emotional engagement and motivation (Schaefer, 2014).

A total of 27 RCTs were found that evaluated rhythmic auditory stimulation for lower extremity motor rehabilitation. Five RCTs compared Treadmill Training with Rhythmic Auditory Stimulation with Treadmill Training (Ahmed et al. 2023; Mainka et al. 2018; Song & Ryu 2016; Yang et al. 2016; Yoon & Kang 2016). Eleven RCTs compared Overground Gait Training with Rhythmic Auditory Stimulation with Overground Gait Training (Awad et al. 2024; Osundiya et al. 2023; Elsner et al. 2020; Lee et al. 2018b; Cha et al. 2014b; Suh et al. 2014b; Kim & Oh 2012b; Johannsen et al. 2010; Thaut et al. 2007; Schauer et al. 2003; Thaut et al. 1997). Five RCTs compared Physical Therapy with Rhythmic Auditory Feedback with Physical Therapy or Conventional Therapy (Rana et al. 2024; Young et al. 2021; Bunketorp-Käll et al. 2017; Raglio et al. 2017; Jeong & Kim 2007). One RCT compared Treadmill Training with Rhythmic Auditory Stimulation with Overground Gait with Rhythmic Auditory Stimulation (Park et al. 2015a). One RCT compared Auditory Stimulation with Robot Training with Virtual Reality with Robot Training or Conventional Training (Park et al. 2018a). One RCT compared Auditory Stimulation with Mental Imagery with Mental Imagery (Kim et al. 2011). One RCT compared Rhythmic Auditory Stimulation with Visual Cueing or Conventional Treatment (Chouhan et al. 2012). One RCT evaluated Action Observation with Rhythmic Auditory Stimulation (Cho et al. 2020a).

In addition, one RCT in which rhythmic auditory stimulation formed part of a combined or comparative intervention are cross-referenced at the end of Table 22; their primary listings appear in other tables.

The methodological details and results of all 27 RCTs are presented in Table 22.

Table 22. RCTs Evaluating Rhythmic Auditory Stimulation for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)

Treadmill Training with Rhythmic Auditory Stimulation vs Treadmill Training		
Ahmed et al. (2023) RCT (7) Nstart=30 Nend=30 TPS=Chronic A + B + C vs B + C Also in Table 9 (Treadmill Training)	E: Rhythmic Auditory Stimulation + Custom Physiotherapy program + Treadmill gait training C: Custom physiotherapy program + Treadmill gait training Duration: 30 mins/d, 3ds/wk, 6 wks	E vs C: Walking speed improvement (+exp) Step cycle improvement (+exp) Step length improvement affected side (+exp) non-affected (-) Percent of time on improvement affected side (+exp) non-affected side (-) Ambulation index improvement (+exp)
Mainka et al. (2018) RCT (6) Nstart=45 Nend=35 TPS=Subacute A + B vs B vs C Also in Table 9 (Treadmill Training)	E1: Rhythmic auditory stimulation + treadmill training + conventional PT E2: Treadmill training + conventional PT C: Neurodevelopmental treatment + conventional PT Duration: 15-20min/d, 5d/wk, for 4wks treadmill training with or without the Rhythmic auditory stimulation & 30min/d, 5d/wk, for 4wks Neurodevelopmental treatment & 30-60min/wk conventional PT	E1 vs E2: Fast gait speed test gait velocity(+exp1) cadence (+exp1) stride length(-) Gait analysis with the locometre gait velocity(-) cadence (-) stride length(-) 3-min walking test (+exp1) instrumental evaluation of balance (-) E1/E2 vs C: Fast gait speed test gait velocity(+exp1) cadence (+exp1) stride length(-) Gait analysis with the locometre gait velocity(-) cadence (+exp1) stride length(-) 3-min walking test (-) instrumental evaluation of balance (-)

Raglio et al. (2017) RCT (6) Nstart=38 Nend=38 TPS=Subacute A vs 0	E: Relational active music therapy + Standard rehabilitation C: Standard rehabilitation only Duration: 30min/d, 3d/wk, 20sessions music therapy & 7d/wk standard rehabilitation	E vs C: NIHSS-Italian (-) Functional independence measure (-) Grip pinch test Dominant hand grip (-) Nondominant hand grip (+exp) Dominant hand pinch (-) Nondominant hand pinch (-) 9Hole Peg test Dominant hand (-) Nondominant hand (-) Timed Up and Go (-) Hospital Anxiety and Depression scale

		Anxiety (-) Depression (+exp) McGill Quality of life questionnaire (-)
Jeong & Kim (2007) RCT (5) Nstart=36 Nend=33 TPS=Chronic A + B vs C	E: Movement exercise + Rhythmic auditory stimulation C: Referral information about usual care Duration: 2hr/wk, for 8wks	E vs C: Active Range of motion: Shoulder flexion (-) Ankle flexion (-) Ankle extension (+exp) Back scratch test Upward the affected arm (+exp) Downward the affected arm (+exp) Profile of Mood states (+exp) Relationship Change Scale (+exp) Stroke Specific Quality of life (-)
Treadmill Training with Rhythmic Auditory Stimulation vs Overground Gait with Rhythmic Auditory Stimulation		
Park et al. (2015a) RCT (5) Nstart=19 Nend=19 TPS=Chronic A + B vs C + B Also in Table 9 (Treadmill Training)	E: Treadmill training + Rhythmic auditory stimulation C: Overground training + Rhythmic auditory stimulation Duration: 30min/d, 5d/wk for 3wks	E vs C: Gait speed (+exp) 6-Minute Walk Test (+exp) Functional Gait Assessment (+exp) Step cycle (+exp) Step length Paretic side (-) Nonparetic side (+exp) Timed Up & Go Test (-)
Auditory Stimulation with Robot Training vs Virtual Reality with Robot Training or Conventional Training		
Park et al. (2018a) RCT (6) Nstart=40 Nend=40 TPS=Chronic A + B vs C + B vs D Also in Table 9 (Treadmill Training); Table 26 (Virtual Reality); Table 27 (Electromechanical and Robotic Devices)	E1: Virtual reality + robot- assisted gait training (Treadmill)+ conventional physical therapy E2: Auditory stimulation + robot- assisted gait training (Treadmill) + conventional physical therapy C: Conventional physical therapy + treadmill training Duration: 45min/d, 3d/wk, for 6wks trainings & 30min/d, 5d/wk, for 6wks Conventional therapy	E1 vs E2: Medical Research Council (+exp1) Berg Balance Scale (-) Timed Up & Go Test (-) 10 Meter Walk test (-) Fugl-Meyer Assessment (+exp1) Modified Barthel Index (-) E1/ E2 vs C: Medical Research Council (+exp1+exp2) Berg Balance Scale (+exp1, +exp2) Timed Up & Go Test (+exp1, +exp2) 10 Meter Walk test (+exp1) Fugl-Meyer Assessment (+exp1) Modified Barthel Index (-)
Auditory Stimulation with Mental Imagery vs Mental Imagery		
Kim et al. (2011) RCT crossover (4) Nstart=18 Nend=15 TPS=Chronic A1 vs A2 vs B1 vs B2 Also in Table 17 (Mental Practice)	E1: Visual Locomotor Imagery Training E2: Kinesthetic Locomotor Imagery Training E3: Visual Locomotor Training with Auditory Step Rhythm E4: Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm Duration: 15 min/condition, 24 hr washout	E1 vs E2: Timed Up and Go Test (-) E1 vs E3: Timed Up and Go Test (-) E1 vs E4: Timed Up and Go Test (+exp4) muscle activation by EMG parameter (+exp4) E2 vs E3: Timed Up and Go Test (-) E2 vs E4: Timed Up and Go Test (-)

		E3 vs E4: Timed Up and Go Test (-)
Rhythmic Auditory Stimulation vs. Visual Cueing or Conventional Treatment		
Chouhan et al. (2012) RCT (6) Nstart=45 Nend=45 TPS=Subacute A vs B vs 0	E1: Rhythmic auditory stimulation + conventional treatment E2: Visual cueing + conventional treatment C: Conventional treatment Duration: 120min/d, 3d/wk, for 3wks	E1 vs E2: Dynamic gait index (+exp2) Fugl-Meyer Assessment (-) E1/E2 vs C: Dynamic gait index (+exp1, +exp2) Fugl-Meyer Assessment (+exp1, exp2)
Action Observation with Rhythmic Auditory Stimulation		
Cho et al. (2020a) RCT (6) Nstart=30 Nend=30 TPS=Chronic A + B vs A Also in Table 18 (Action Observation)	E: Action observation training + Rhythmic auditory stimulation + PT C: Action observation + PT Duration: 15min, 2sessions/d, 3d/wk, 8wks action observation & 5d/wk, for 8wks PT	E vs C: Postural stability test Overall balance index (+exp) Anteroposterior balance index (+exp) Mediolateral balance index (+exp) Fall Risk (+exp)
Additional Comparisons from the Source Dataset		
Jun et al. (2013) RCT (3) Nstart=40 Nend=30 TPS=Acute A vs 0	E: Music-movement therapy (MMT) C: Conventional care Duration: 60min/d, 3d/wk, 8wks	E vs C: Hip Range of Motion (-) Medical research council scale (-) Modified Barthel Index Profile of Mood States (+exp) Center for Epidemiological Studies of Depression scale (-).

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Overground Gait Training with Rhythmic Auditory Stimulation may not have a difference in efficacy when compared to Overground Gait Training for improving motor recovery.	3	Osundiya et al. 2023; Lee et al. 2018b; Johannsen et al. 2010
1b	Physical Therapy with Rhythmic Auditory Feedback may not have a difference in efficacy when compared to Physical Therapy or Conventional Therapy for improving motor recovery.	1	Raglio et al. 2017
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may produce greater improvements in motor recovery than Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.	1	Park et al. 2018a
1b	Auditory Stimulation with Robot Training may produce greater improvements in motor recovery than Virtual Reality with Robot Training or Conventional Training.	1	Park et al. 2018a

1b	Rhythmic auditory stimulation with conventional treatment may not have a difference in efficacy when compared to Visual cueing with conventional treatment for improving motor recovery.	1	Chouhan et al. 2012
1b	Rhythmic auditory stimulation with conventional treatment or Visual cueing with conventional treatment may produce greater improvements in motor recovery than Conventional treatment.	1	Chouhan et al. 2012

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Treadmill Training with Rhythmic Auditory Stimulation when compared to Treadmill Training for improving biomechanical gait measures.	5	Ahmed et al. 2023; Mainka et al. 2018; Song & Ryu 2016; Yang et al. 2016; Yoon & Kang 2016
2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in biomechanical gait measures than Inclined treadmill training.	1	Yoon & Kang 2016
2	There is conflicting evidence about the effect of Inclined treadmill training when compared to Treadmill training for improving biomechanical gait measures.	1	Yoon & Kang 2016
1a	There is conflicting evidence about the effect of Overground Gait Training with Rhythmic Auditory Stimulation when compared to Overground Gait Training for improving biomechanical gait measures.	9	Elsner et al. 2020; Lee et al. 2018b; Cha et al. 2014b; Suh et al. 2014b; Kim & Oh 2012b; Johannsen et al. 2010; Thaut et al. 2007; Schauer et al. 2003; Thaut et al. 1997
2	There is conflicting evidence about the effect of Treadmill Training with Rhythmic Auditory Stimulation when compared to Overground Gait with Rhythmic Auditory Stimulation for improving biomechanical gait measures.	1	Park et al. 2015a

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Treadmill Training with Rhythmic Auditory Stimulation may not have a difference in efficacy when compared to Treadmill Training for improving biomechanical balance measures.	1	Mainka et al. 2018
1b	Overground Gait Training with Rhythmic Auditory Stimulation may produce greater improvements in biomechanical balance measures than Overground Gait Training.	1	Suh et al. 2014b
1b	Action observation training with Rhythmic auditory stimulation and physical therapy may produce greater improvements in biomechanical balance measures than Action observation with physical therapy.	1	Cho et al. 2020a

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may produce greater improvements in muscle strength than Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.	1	Park et al. 2018a
1b	Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy or Auditory stimulation with robot-assisted gait training (Treadmill) with conventional physical therapy may produce greater improvements in muscle strength than Conventional physical therapy with treadmill training.	1	Park et al. 2018a

2	Music-movement therapy (MMT) may not have a difference in efficacy when compared to Conventional care for improving muscle strength.	1	Jun et al. 2013

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	There is conflicting evidence about the effect of Physical Therapy with Rhythmic Auditory Feedback when compared to Physical Therapy or Conventional Therapy for improving range of motion.	1	Jeong & Kim 2007
2	Music-movement therapy (MMT) may not have a difference in efficacy when compared to Conventional care for improving range of motion.	1	Jun et al. 2013

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Overground Gait Training with Rhythmic Auditory Stimulation may produce greater improvements in neurophysiological measures than Overground Gait Training.	1	Thaut et al. 1997
2	Visual Locomotor Imagery Training may result in lesser improvements in neurophysiological measures when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.	1	Kim et al. 2011

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Overground Gait Training with Rhythmic Auditory Stimulation may not have a difference in efficacy when compared to Overground Gait Training for improving activities of daily living.	1	Osundiya et al. 2023
1b	Physical Therapy with Rhythmic Auditory Feedback may not have a difference in efficacy when compared to Physical Therapy or Conventional Therapy for improving activities of daily living.	1	Raglio et al. 2017
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may not have a difference in efficacy when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy for improving activities of daily living.	1	Park et al. 2018a
1b	Auditory Stimulation with Robot Training may not have a difference in efficacy when compared to Virtual Reality with Robot Training or Conventional Training for improving activities of daily living.	1	Park et al. 2018a

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Treadmill Training with Rhythmic Auditory Stimulation when compared to Treadmill Training for improving gait speed.	5	Ahmed et al. 2023; Mainka et al. 2018; Song & Ryu 2016; Yang et al. 2016; Yoon & Kang 2016
2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in gait speed than Inclined treadmill training.	1	Yoon & Kang 2016
2	Inclined treadmill training may produce greater improvements in gait speed than Treadmill training.	1	Yoon & Kang 2016

1a	Overground Gait Training with Rhythmic Auditory Stimulation may produce greater improvements in gait speed than Overground Gait Training.	10	Awad et al. 2024; Elsner et al. 2020; Lee et al. 2018b; Cha et al. 2014b; Suh et al. 2014b; Kim & Oh 2012b; Johannsen et al. 2010; Thaut et al. 2007; Schauer et al. 2003; Thaut et al. 1997

2	Visual Locomotor Training with Auditory Step Rhythm may not have a difference in efficacy when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm for improving functional mobility.	1	Kim et al. 2011
2	Visual Locomotor Imagery Training may result in lesser improvements in functional mobility when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.	1	Kim et al. 2011
1b	Rhythmic auditory stimulation with conventional treatment may result in lesser improvements in functional mobility when compared to Visual cueing with conventional treatment.	1	Chouhan et al. 2012
1b	Rhythmic auditory stimulation with conventional treatment or Visual cueing with conventional treatment may produce greater improvements in functional mobility than Conventional treatment.	1	Chouhan et al. 2012

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Treadmill Training with Rhythmic Auditory Stimulation may produce greater improvements in balance than Treadmill Training.	1	Yoon & Kang 2016
2	Inclined treadmill training with Rhythmic auditory stimulation may produce greater improvements in balance than Inclined treadmill training.	1	Yoon & Kang 2016
2	Inclined treadmill training may produce greater improvements in balance than Treadmill training.	1	Yoon & Kang 2016
1a	Overground Gait Training with Rhythmic Auditory Stimulation may not have a difference in efficacy when compared to Overground Gait Training for improving balance.	3	Elsner et al. 2020; Lee et al. 2018b; Cha et al. 2014b
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may not have a difference in efficacy when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy for improving balance.	1	Park et al. 2018a

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Action observation training with Rhythmic auditory stimulation and physical therapy may produce greater improvements in falls and fear of falling than Action observation with physical therapy.	1	Cho et al. 2020a

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Overground Gait Training with Rhythmic Auditory Stimulation may produce greater improvements in quality of life than Overground Gait Training.	1	Cha et al. 2014b
1b	Physical Therapy with Rhythmic Auditory Feedback may not have a difference in efficacy when compared to Physical Therapy or Conventional Therapy for improving quality of life.	2	Raglio et al. 2017; Jeong & Kim 2007

Other Associated Outcome Measures

MOOD			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Physical Therapy with Rhythmic Auditory Feedback may produce greater improvements in mood than Physical Therapy or Conventional Therapy.	2	Raglio et al. 2017; Jeong & Kim 2007
2	There is conflicting evidence about the effect of Music-movement therapy (MMT) when compared to Conventional care for improving mood.	1	Jun et al. 2013

FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Physical Therapy with Rhythmic Auditory Feedback may not have a difference in efficacy when compared to Physical Therapy or Conventional Therapy for improving fatigue and sleep.	1	Young et al. 2021

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Overground Gait Training with Rhythmic Auditory Stimulation may result in lesser improvements in upper extremity function when compared to Overground Gait Training.	1	Johannsen et al. 2010
1a	Physical Therapy with Rhythmic Auditory Feedback may not have a difference in efficacy when compared to Physical Therapy or Conventional Therapy for improving upper extremity function.	3	Bunketorp-Käll et al. 2017; Raglio et al. 2017; Jeong & Kim 2007

Key Points

- Treadmill Training with Rhythmic Auditory Stimulation may be beneficial for improving gait endurance, functional mobility, and balance, but not biomechanical balance measures, after stroke when compared to Treadmill Training; the literature is mixed regarding biomechanical gait measures and gait speed.
- Overground Gait Training with Rhythmic Auditory Stimulation may be beneficial for improving biomechanical balance measures, neurophysiological measures, gait speed, and quality of life, but not

motor recovery, activities of daily living, gait endurance, functional mobility, and balance, after stroke when compared to Overground Gait Training; the literature is mixed regarding biomechanical gait measures.

- Physical Therapy with Rhythmic Auditory Feedback may not be beneficial for improving motor recovery, activities of daily living, gait endurance, functional mobility, and quality of life after stroke when compared to Physical Therapy or Conventional Therapy; the literature is mixed regarding range of motion.
- Treadmill Training with Rhythmic Auditory Stimulation may be beneficial for improving gait speed, gait endurance, and functional mobility after stroke when compared to Overground Gait with Rhythmic Auditory Stimulation; the literature is mixed regarding biomechanical gait measures.
- Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may be beneficial for improving motor recovery and muscle strength, but not activities of daily living, gait speed, functional mobility, and balance, after stroke when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.
- Auditory Stimulation with Robot Training may be beneficial for improving motor recovery and gait speed, but not activities of daily living, after stroke when compared to Virtual Reality with Robot Training or Conventional Training.
- Visual Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training.
- Visual Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Visual Locomotor Training with Auditory Step Rhythm.
- Kinesthetic Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.
- Kinesthetic Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Visual Locomotor Training with Auditory Step Rhythm.
- Visual Locomotor Training with Auditory Step Rhythm may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.
- Action observation training with Rhythmic auditory stimulation and physical therapy may be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Action observation with physical therapy.
- Music-movement therapy (MMT) may not be beneficial for improving muscle strength and range of motion after stroke when compared to Conventional care.
- Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- Auditory stimulation with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- Inclined treadmill training may be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Treadmill training; the literature is mixed regarding biomechanical gait measures.
- Inclined treadmill training with Rhythmic auditory stimulation may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Inclined treadmill training.
- Rhythmic auditory stimulation with conventional treatment may not be beneficial for improving motor recovery after stroke when compared to Visual cueing with conventional treatment; Rhythmic auditory stimulation with conventional treatment may result in lesser improvements in functional mobility when compared to Visual cueing with conventional treatment.
- Rhythmic auditory stimulation with conventional treatment may be beneficial for improving motor recovery and functional mobility after stroke when compared to Conventional treatment.
- Visual cueing with conventional treatment may be beneficial for improving motor recovery and functional mobility after stroke when compared to Conventional treatment.

- Visual Locomotor Imagery Training may result in lesser improvements in neurophysiological measures and functional mobility when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.

Summary of Key Points: Rhythmic Auditory Stimulation

Intervention	Control(s)	Function domain(s)	Effect
Treadmill Training with Rhythmic Auditory Stimulation	Treadmill Training	Gait endurance, functional mobility, balance	+
Treadmill Training with Rhythmic Auditory Stimulation	Treadmill Training	Biomechanical balance measures	–
Treadmill Training with Rhythmic Auditory Stimulation	Treadmill Training	Gait endurance	+
Treadmill Training with Rhythmic Auditory Stimulation	Treadmill Training	Gait speed, biomechanical gait measures	=
Overground Gait Training with Rhythmic Auditory Stimulation	Overground Gait Training	Biomechanical balance measures, neurophysiological measures, gait speed, quality of life	+
Overground Gait Training with Rhythmic Auditory Stimulation	Overground Gait Training	Motor recovery, activities of daily living, gait endurance, functional mobility, balance	–
Overground Gait Training with Rhythmic Auditory Stimulation	Overground Gait Training	Biomechanical gait measures	=
Physical Therapy with Rhythmic Auditory Feedback	Physical Therapy or Conventional Therapy	Motor recovery, activities of daily living, gait endurance, functional mobility, quality of life	–
Physical Therapy with Rhythmic Auditory Feedback	Physical Therapy or Conventional Therapy	Range of motion	=
Treadmill Training with Rhythmic Auditory Stimulation	Overground Gait with Rhythmic Auditory Stimulation	Gait speed, gait endurance, functional mobility	+
Treadmill Training with Rhythmic Auditory Stimulation	Overground Gait with Rhythmic Auditory Stimulation	Biomechanical gait measures	=
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy	Motor recovery, muscle strength	+
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy	Activities of daily living, gait speed, functional mobility, balance	–
Auditory Stimulation with Robot Training	Virtual Reality with Robot Training or Conventional Training	Motor recovery, gait speed	+
Auditory Stimulation with Robot Training	Virtual Reality with Robot Training or Conventional Training	Activities of daily living	–
Visual Locomotor Imagery Training	Kinesthetic Locomotor Imagery Training	Functional mobility	–
Visual Locomotor Imagery Training	Visual Locomotor Training with Auditory Step Rhythm	Functional mobility	–
Kinesthetic Locomotor Imagery Training	Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm	Functional mobility	–
Kinesthetic Locomotor Imagery Training	Visual Locomotor Training with Auditory Step Rhythm	Functional mobility	–

Visual Locomotor Training with Auditory Step Rhythm	Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm	Functional mobility	−
Action observation training with Rhythmic auditory stimulation and physical therapy	Action observation with physical therapy	Biomechanical balance measures, falls and fear of falling	+
Music-movement therapy (MMT)	Conventional care	Muscle strength, range of motion	−
Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy	Conventional physical therapy with treadmill training	Muscle strength	+
Auditory stimulation with robot-assisted gait training (Treadmill) with conventional physical therapy	Conventional physical therapy with treadmill training	Muscle strength	+
Inclined treadmill training	Treadmill training	Biomechanical gait measures	=
Inclined treadmill training	Treadmill training	Gait speed, gait endurance, functional mobility, balance	+
Inclined treadmill training with Rhythmic auditory stimulation	Inclined treadmill training	Biomechanical gait measures, gait speed, gait endurance, functional mobility, balance	+
Rhythmic auditory stimulation with conventional treatment	Visual cueing with conventional treatment	Motor recovery, functional mobility	−
Rhythmic auditory stimulation with conventional treatment	Conventional treatment	Motor recovery, functional mobility	+
Visual cueing with conventional treatment	Conventional treatment	Motor recovery, functional mobility	+
Visual Locomotor Imagery Training	Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm	Neurophysiological measures, functional mobility	−

Respiratory Training and Devices

Adopted from: https://unsplash.com/

After a stroke, not only are muscles of the upper and lower extremities impacted, but patients can also experience respiratory muscle weakness (Liaw et al., 2020). The respiratory muscle strength post-stroke can be less than half of what would be expected for a healthy adult (Menezes et al., 2016). This weakness impacts swallowing and cough ability, which in turn can lead to secondary complications such as aspiration, pneumonia or respiratory failure (Zhang et al., 2022a). To avoid these post-stroke complications, patients can participate in respiratory muscle training. Patients repeat breathing exercises with a device that provides a pressure threshold or flow- dependent resistance against exhalation or inhalation (Menezes et al., 2016; Zhang et al., 2024). This resistance stimulates the respiratory muscles, which in turn must adapt their structure (Zhang et al., 2024; Menezes et al., 2016). This training should increase muscle strength.

A total of ten RCTs were found that evaluated respiratory training and devices for lower extremity motor rehabilitation. Six RCTs compared Respiratory Muscle Training with Conventional Rehabilitation or Sham Respiratory Muscle Training (Dogan et al. 2024; Aydogan Arslan et al. 2022; Choi et al. 2021b; Vaz et al. 2021; Yoo et al. 2018b; Kim et al. 2014b). One RCT compared Respiratory Training with Conventional Rehabilitation with Liuzijue Qigong (Zheng et al. 2021). One RCT compared Continuous Positive Airway Pressure with Conventional Rehabilitation (Ryan et al. 2011). One RCT compared Respiratory Muscle Training with Cycle Ergometer Training (Jeong-MinYoon et al. 2022).

The methodological details and results of all ten RCTs are presented in Table 23.

Table 23. RCTs Evaluating Respiratory Training and Devices for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Respiratory Muscle Training vs Conventional Rehabilitation or Sham Respiratory Muscle Training		
Dogan et al. (2024) RCT (7) Nstart=60 Nend=50 TPS=Chronic A1 vs A2 vs 0	E1: 4 week inspiratory muscle training E2: 8 week inspiratory muscle training C: Sham inspiratory muscle training Duration: Experimental 1: 30 mins/d, 5ds/wk, 4wks; Experimental 2 and Control: 30 mins/d, 5ds/wk, 8wks	E1 vs E2: Maximum inspiratory pressure (+exp2) 6-minute walk test (+exp2) Nottingham extended activities of daily living index (-) E1 vs C: Maximum inspiratory pressure (+exp1) 6-minute walk test (+exp1) Nottingham extended activities of daily living index (-) E2 vs C: Maximum inspiratory pressure (+exp2) 6-minute walk test (+exp2) Nottingham extended activities of daily living index (-)
Aydogan Arslan et al. (2022) RCT (7) Nstart=21 Nend=21 TPS=Chronic A + B vs B Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)	E: Inspiratory Muscle Training + Neurodevelopmental Bobath Treatment C: Neurodevelopmental Bobath Treatment Duration: IMT (30mins/d, 7ds/wk, 6wks)	E vs C: Respiratory measures Forced vital capacity (-) Forced expiratory volume in 1 second (-) Peak expiratory volume (+exp) FEV1/FVC Ratio (-) Maximum inspiratory pressure (+exp) Maximum expiratory pressure (-) TIS (+exp) TUG (-) Berg Balance Scale (-) 6MWT (-)
Choi et al. (2021b) RCT (3) Nstart=64 Nend=44 TPS=Subacute A vs 0	E: Respiratory muscle training + Conventional rehabilitation C: Conventional rehabilitation Duration: 30min/sessions, 5d/wk for 1mo RMT	E vs C: Pulmonary function test (-) Functional ambulation category (-) Modified Barthel Index (+exp) Manual Muscle test- Shoulder Abduction and Finger Extension (-) Grip strength right (-) left (+exp)

		occurrence of pneumonia (+exp)
Vaz et al. (2021) RCT (7) Nstart=50 Nend=42 TPS=Chronic A vs 0	E: Inspiratory Muscle Training + standard rehabilitation C: Sham Inspiratory Muscle Training + standard rehabilitation Duration: 15min/session, 2sessions/d, 5d/wk for 6wks	E vs C: 6-min Walking Test (-) Maximal Inspiratory Pressure (-) Maximal Expiratory Pressure (-) Inspiratory Muscle Endurance (+exp) Functional Independence Measure (-) Quality of Life (-)
Yoo et al. (2018b) RCT (5) Nstart=45 Nend=40 TPS=Acute A vs 0	E: Respiratory muscle training + conventional rehabilitation C: Conventional rehabilitation Duration: 60min/d, 7d/wk respiratory muscle training & 60min/d, 5d/wk, for 3wks conventional rehabilitation	E vs C: Forced Vital Capacity (-) Forced Expiratory Volume (+exp) FEV1/FVC (-) Peak Flow (+exp) National Institutes of Health Stroke Scale (-) Modified Barthel Index (-) Berg Balance Scale (-) Fugl-Meyer Assessment (-) Mini-Mental State Examination (-) Incidence of pneumonia (-)
Kim et al. (2014b) RCT (4) Nstart=20 Nend=20 TPS=Chronic A + B vs A	E: Conventional exercise + automated full-body workout machine + respiratory training C: Conventional exercise + automated full-body workout machine Duration: 30min/d, 3d/wk, for 4wks conventional exercise & 20min/d, 3d/wk, for 4wks automated full-body workout machine & 20min/d respiratory training, 3d/wk, for 4wks	E vs C: Forced vital capacity (FVC) (+exp) Forced expiratory volume (FEV1) (+exp) FEV1/FVC (-) Peak expiratory flow (+exp) 6-Minute Walk Test (+exp) Shortness of Breath Modified Borg Dyspnea Scale (+exp)
Respiratory Training vs Conventional Rehabilitation with Liuzijue Qigong		
Zheng et al. (2021) RCT (8) Nstart=60 Nend=60 TPS=Acute A vs B	E: Conventional rehabilitation training with Liuzijue Qigong C: Respiratory relaxation training + conventional training Duration: 45min/d, 5d/wk, for 3wks	E vs C: Trunk Impairment Scale Static sitting balance (+exp) Dynamic sitting balance (+exp) Coordination of trunk movement (+exp) Maximum expiratory pressure (+exp) Maximum inspiratory pressure (+exp) Forced expiratory volume in the first second (-) Forced vital capacity (-) Peak expiratory flow (-) Maximum expiratory mid-flow (-) Diaphragmatic movement (-) Change of intra-abdominal pressure (+exp) Berg Balance Scale (-) Modified Barthel Index (+exp)
Continuous Positive Airway Pressure vs Conventional Rehabilitation		
Ryan et al. (2011) RCT (7) Nstart=48 Nend=44 TPS=Acute	E: Continuous positive airway pressure (CPAP) + standard rehabilitation C: Standard rehabilitation Duration: 6h/d, 4wks CPAP, 45min/d, 5d/wk, 4wks standard rehabilitation	E vs C: Canadian Neurologic scale (+exp) cognitive (+exp) motor (+exp) 6min Walk test (-)

A vs 0		Sustained attention response time (-) Digit/spatial span-backward (-) Functional Independence measure (-) motor (+exp) cognitive (-) Chedoke-McMaster Stroke assessment (+exp) Hand-grip affected/nonaffected ratio (-) Berg Balance scale (-) Epworth Sleepiness scale (+exp) Stanford Sleepiness scale (+exp) Perdue pegboard test (-) Beck Depression inventory-1 (-) somatic (-) affective (+exp)
Respiratory Muscle Training vs Cycle Ergometer Training		
Jeong-MinYoon et al. (2022) RCT (6) Nstart=32 Nend=32 TPS=Chronic A vs B	E: Breathing exercises C: Non-resistant cycle ergometer exercise Duration: 20min/d, 3d/wk, 4wks	E vs C: 6MWT (-) chest expansion (-) forced vital capacity (+exp) forced expiratory volume (+exp) peak expiratory flow (+exp)
Additional Comparisons from the Source Dataset		
Sütbeyaz et al. (2010) RCT (7) Nstart=45 Nend=45 TPS=Subacute A vs 0	E1: Inspiratory muscle training (IMT) E2: Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT) C: Conventional rehabilitation Duration: 30mins/d, 6d/wk, 6wks	E1 vs E2: Respiratory Measures FEV (+exp1) FVC (+exp1) VC (+exp1) FEF 25-75% (+exp1) MVV (+exp1) PEF (+exp2) VO2peak (+exp1) Borg rating of perceived effort (+exp1) E1 vs C: Respiratory Measures FEV (+exp1) FVC (+exp1) VC (+exp1) FEF 25-75% (+exp1) MVV (+exp1) VO2peak (+exp1) Borg rating of perceived effort (+exp1) Barthel Index (+exp1) Functional Ambulation Category (+exp1) Short Form 36 physical role (+exp1) general health (+exp1) vitality (+exp1) E2 vs C ; ;Respiratory Measures ; - FEV (-) ; - FVC (-) VC (-) ; - FEF 25-75% (-) ; - MVV (-) ; - PEF (+exp2) ; - VO2peak (-); ; Borg rating of perceived effort (-)

		Barthel Index (-) Functional Ambulation Category (-) Short Form 36 ; - emotional role (+exp2) ; - general health (+exp2) ; - vitality (+exp2) ; - pain (+exp2)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Respiratory Muscle Training may not have a difference in efficacy when compared to Conventional Rehabilitation or Sham Respiratory Muscle Training for improving motor recovery.	1	Yoo et al. 2018b

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Respiratory Muscle Training when compared to Conventional Rehabilitation or Sham Respiratory Muscle Training for improving muscle strength.	2	Choi et al. 2021b; Vaz et al. 2021

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	4 week inspiratory muscle training may result in lesser improvements in aerobic measures when compared to 8 week inspiratory muscle training.	1	Dogan et al. 2024
1a	Respiratory Muscle Training may produce greater improvements in aerobic measures than Conventional Rehabilitation or Sham Respiratory Muscle Training.	5	Dogan et al. 2024; Aydogan Arslan et al. 2022; Vaz et al. 2021; Yoo et al. 2018b; Kim et al. 2014b
1b	Respiratory Training may not have a difference in efficacy when compared to Conventional Rehabilitation with Liuzijue Qigong for improving aerobic measures.	1	Zheng et al. 2021
1b	Respiratory Muscle Training may produce greater improvements in aerobic measures than Cycle Ergometer Training.	1	Jeong-MinYoon et al. 2022
1b	Inspiratory muscle training (IMT) may produce greater improvements in aerobic measures than Conventional rehabilitation.	1	Sütbeyaz et al. 2010
1b	Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT) may not have a difference in efficacy when compared to Conventional rehabilitation for improving aerobic measures.	1	Sütbeyaz et al. 2010
1b	Inspiratory muscle training (IMT) may produce greater improvements in aerobic measures than Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT).	1	Sütbeyaz et al. 2010

PAIN			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Inspiratory muscle training (IMT) may not have a difference in efficacy when compared to Conventional rehabilitation for improving pain.	1	Sütbeyaz et al. 2010
1b	Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT) may produce greater improvements in pain than Conventional rehabilitation.	1	Sütbeyaz et al. 2010

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	4 week inspiratory muscle training may not have a difference in efficacy when compared to 8 week inspiratory muscle training for improving activities of daily living.	1	Dogan et al. 2024
1a	Respiratory Muscle Training may not have a difference in efficacy when compared to Conventional Rehabilitation or Sham Respiratory Muscle Training for improving activities of daily living.	4	Dogan et al. 2024; Choi et al. 2021b; Vaz et al. 2021; Yoo et al. 2018b
1b	Respiratory Training may produce greater improvements in activities of daily living than Conventional Rehabilitation with Liuzijue Qigong.	1	Zheng et al. 2021
1b	Continuous Positive Airway Pressure may not have a difference in efficacy when compared to Conventional Rehabilitation for improving activities of daily living.	1	Ryan et al. 2011
1b	There is conflicting evidence about the effect of Inspiratory muscle training (IMT) when compared to Conventional rehabilitation for improving activities of daily living.	1	Sütbeyaz et al. 2010
1b	Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT) may not have a difference in efficacy when compared to Conventional rehabilitation for improving activities of daily living.	1	Sütbeyaz et al. 2010

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	4 week inspiratory muscle training may result in lesser improvements in gait endurance when compared to 8 week inspiratory muscle training.	1	Dogan et al. 2024
1a	Respiratory Muscle Training may produce greater improvements in gait endurance than Conventional Rehabilitation or Sham Respiratory Muscle Training.	4	Dogan et al. 2024; Aydogan Arslan et al. 2022; Vaz et al. 2021; Kim et al. 2014b
1b	Continuous Positive Airway Pressure may not have a difference in efficacy when compared to Conventional Rehabilitation for improving gait endurance.	1	Ryan et al. 2011
1b	Respiratory Muscle Training may not have a difference in efficacy when compared to Cycle Ergometer Training for improving gait endurance.	1	Jeong-MinYoon et al. 2022

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Respiratory Muscle Training may not have a difference in efficacy when compared to Conventional Rehabilitation or Sham Respiratory Muscle Training for improving functional mobility.	2	Aydogan Arslan et al. 2022; Choi et al. 2021b
1b	Inspiratory muscle training (IMT) may produce greater improvements in functional mobility than Conventional rehabilitation.	1	Sütbeyaz et al. 2010
1b	Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT) may not have a difference in efficacy when compared to Conventional rehabilitation for improving functional mobility.	1	Sütbeyaz et al. 2010

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Respiratory Muscle Training may not have a difference in efficacy when compared to Conventional Rehabilitation or Sham Respiratory Muscle Training for improving balance.	2	Aydogan Arslan et al. 2022; Yoo et al. 2018b
1b	Respiratory Training may produce greater improvements in balance than Conventional Rehabilitation with Liuzijue Qigong.	1	Zheng et al. 2021
1b	Continuous Positive Airway Pressure may not have a difference in efficacy when compared to Conventional Rehabilitation for improving balance.	1	Ryan et al. 2011

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Respiratory Muscle Training may not have a difference in efficacy when compared to Conventional Rehabilitation or Sham Respiratory Muscle Training for improving quality of life.	1	Vaz et al. 2021

Other Associated Outcome Measures

MOOD			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Continuous Positive Airway Pressure may not have a difference in efficacy when compared to Conventional Rehabilitation for improving mood.	1	Ryan et al. 2011

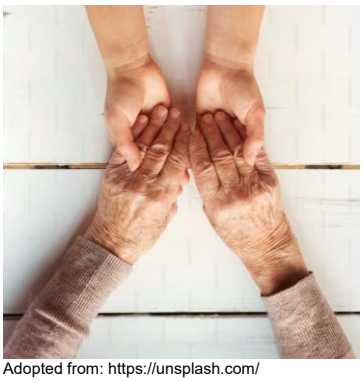
FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Continuous Positive Airway Pressure may produce greater improvements in fatigue and sleep than Conventional Rehabilitation.	1	Ryan et al. 2011

COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Respiratory Muscle Training may not have a difference in efficacy when compared to Conventional Rehabilitation or Sham Respiratory Muscle Training for improving cognition.	1	Yoo et al. 2018b

1b	Continuous Positive Airway Pressure may not have a difference in efficacy when compared to Conventional Rehabilitation for improving cognition.	1	Ryan et al. 2011

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Respiratory Muscle Training may produce greater improvements in upper extremity function than Conventional Rehabilitation or Sham Respiratory Muscle Training.	1	Choi et al. 2021b

Key Points



- 4 week inspiratory muscle training may not be beneficial for improving activities of daily living after stroke when compared to 8 week inspiratory muscle training; 4 week inspiratory muscle training may result in lesser improvements in aerobic measures and gait endurance when compared to 8 week inspiratory muscle training.
- Respiratory Muscle Training may be beneficial for improving aerobic measures and gait endurance, but not motor recovery, activities of daily living, functional mobility, balance, and quality of life, after stroke when compared to Conventional Rehabilitation or Sham Respiratory Muscle Training; the literature is mixed regarding muscle strength.
- Respiratory Training may be beneficial for improving activities of daily living and balance, but not aerobic measures, after stroke when compared to Conventional Rehabilitation with Liuzijue Qigong.
- Continuous Positive Airway Pressure may not be beneficial for improving activities of daily living, gait endurance, and balance after stroke when compared to Conventional Rehabilitation.
- Respiratory Muscle Training may be beneficial for improving aerobic measures, but not gait endurance, after stroke when compared to Cycle Ergometer Training.
- Inspiratory muscle training (IMT) may be beneficial for improving aerobic measures and functional mobility, but not pain, after stroke when compared to Conventional rehabilitation; the literature is mixed regarding activities of daily living.
- Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT) may be beneficial for improving pain, but not aerobic measures, activities of daily living, and functional mobility, after stroke when compared to Conventional rehabilitation.
- Inspiratory muscle training (IMT) may be beneficial for improving aerobic measures after stroke when compared to Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT).

Summary of Key Points: Respiratory Training and Devices

Intervention	Control(s)	Function domain(s)	Effect
4 week inspiratory muscle training	8 week inspiratory muscle training	Aerobic measures, activities of daily living, gait endurance	−
4 week inspiratory muscle training	8 week inspiratory muscle training	Aerobic measures, gait endurance	−
Respiratory Muscle Training	Conventional Rehabilitation or Sham Respiratory Muscle Training	Aerobic measures, gait endurance	+
Respiratory Muscle Training	Conventional Rehabilitation or Sham Respiratory Muscle Training	Motor recovery, activities of daily living, functional mobility, balance, quality of life	−
Respiratory Muscle Training	Conventional Rehabilitation or Sham Respiratory Muscle Training	Muscle strength	=
Respiratory Training	Conventional Rehabilitation with Liuzijue Qigong	Activities of daily living, balance	+

Respiratory Training	Conventional Rehabilitation with Liuzijue Qigong	Aerobic measures	−
Continuous Positive Airway Pressure	Conventional Rehabilitation	Activities of daily living, gait endurance, balance	−
Respiratory Muscle Training	Cycle Ergometer Training	Aerobic measures	+
Respiratory Muscle Training	Cycle Ergometer Training	Gait endurance	−
Inspiratory muscle training (IMT)	Conventional rehabilitation	Aerobic measures, functional mobility	+
Inspiratory muscle training (IMT)	Conventional rehabilitation	Pain	−
Inspiratory muscle training (IMT)	Conventional rehabilitation	Activities of daily living	=
Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT)	Conventional rehabilitation	Aerobic measures, activities of daily living, functional mobility	−
Inspiratory muscle training (IMT)	Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT)	Aerobic measures	+
Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT)	Conventional rehabilitation	Pain	+

Home-Based and Caregiver-Mediated Exercise Programs

Adopted from: https://unsplash.com/

Home-based and Caregiver-mediated programs are programs that allow a patient to receive exercise treatment in the comfort of their own home (van den Berg et al., 2016). These programs are run by a person who is not a licensed healthcare professional but instead more of a member of the patient's social network (Wang et al. 2015). This can help a patient feel more comfortable and may decrease their anxiety about starting a new program (van den Berg et al., 2016).

A total of 45 RCTs were found that evaluated Home-Based and Caregiver-Mediated exercise programs for lower extremity motor rehabilitation. 21 RCTs compared Home-Based Physiotherapy and Exercise Programs with Conventional Therapy or No Therapy (Mahmood et al. 2021; Jarbandhan et al. 2022; Guediri et al. 2022; Salgueiro et al. 2022; Mandigout et al. 2021; Saadatnia et al. 2020; Brouwer et al. 2018; Hsieh et al. 2018; Malagoni et al. 2016; Kara et al. 2015; Olaleye et al. 2014; Treger et al. 2014; Lin et al. 2004; McClellan & Ada 2004; Duncan et al. 2003; Roderick et al. 2001; Baskett et al. 1999; Walker et al. 1999; Duncan et al. 1998; Widen Holmqvist et al. 1998; Young et al. 1992). One RCT compared Home-based Oculomotor/Gaze Stability Exercises with Conventional Rehabilitation (Correia et al. 2021). Nine RCTs compared Caregiver-Mediated Programs with Conventional Care (Deng et al. 2024; Feldman et al. 2022; Nordin et al. 2019; Wang et al. 2015; Mudzi et al. 2012; Galvin et al. 2011; Sackley et al. 2006; Mayo et al. 2000; Mant et al. 2000). Seven RCTs compared Nursing Mediated Program with

Conventional Care (Chen et al. 2021a; Wang et al. 2021b; Zhang et al. 2021a; Guan et al. 2019; Zhang et al. 2018; Jones et al. 2005; Hui et al. 1995). One RCT compared Home Based Overground Walking with Home Based Cycling (Mayo et al. 2013). One RCT compared Early Discharged At-Home Supported Training with Conventional Post-Discharge Rehabilitation (Askim et al. 2006). One RCT compared Outpatient Clinic Care Follow-up with Conventional Control (Welin et al. 2010). One RCT compared Specialist Community Rehabilitation with Conventional Rehabilitation (Rudd et al. 1997).

In addition, ten RCTs in which Home-Based and Caregiver-Mediated exercise programs formed part of a combined or comparative intervention are cross-referenced at the end of Table 24; their primary listings appear in other tables.

The methodological details and results of all 45 RCTs are presented in Table 24.

Table 24. RCTs Evaluating Home-Based and Caregiver-Mediated Exercise Programs for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Home-Based Physiotherapy and Exercise Programs vs Conventional Therapy or No Therapy		
Jarbandhan et al. (2022) Feasibility/pilot RCT (3) Nstart=30 Nend=24 TPS=Chronic A vs 0	E: Home-based physiotherapy program supervised in the first 4wk and tele-supervised during the next 4wk C: Usual care Duration: 3d/wk, for 8wks	E vs C: 6MWD (-) DASH (-) Handgrip Paretic hand (-) Handgrip non paretic hand (-) BBS (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1b	Caregiver-mediated exercise program with e-health support with telerehabilitation may not have a difference in efficacy when compared to Conventional therapy for improving muscle strength.	1	Vloothuis et al. 2019
1b	Caregiver-mediated iPad exercise program with FitBit activity monitor (real-time feedback) may not have a difference in efficacy when compared to Usual care for improving muscle strength.	1	Van Den Berg et al. 2016

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Home-Based Physiotherapy and Exercise Programs when compared to Conventional Therapy or No Therapy for improving spasticity.	2	McClellan & Ada 2004; Walker et al. 1999

1b	Caregiver-Mediated Programs may produce greater improvements in spasticity than Conventional Care.	1	Galvin et al. 2011
2	Nursing Mediated Program may produce greater improvements in spasticity than Conventional Care.	1	Chen et al. 2021a
1b	Home-based isometric unilateral strength training with mirror therapy may not have a difference in efficacy when compared to Home-based isometric unilateral strength training for improving spasticity.	1	Simpson et al. 2019
2	Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may not have a difference in efficacy when compared to Botulinum Toxin A Injection for improving spasticity.	1	Roche et al. 2015

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Home-Based Physiotherapy and Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving neurophysiological measures.	1	Mandigout et al. 2021

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Home-Based Physiotherapy and Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving aerobic measures.	2	Guediri et al. 2022; Duncan et al. 2003
1b	Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care may not have a difference in efficacy when compared to Physical Activity with Usual physiotherapy for improving aerobic measures.	1	Wright et al. 2021

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home-Based Physiotherapy and Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving activities of daily living.	13	Guediri et al. 2022; Mandigout et al. 2021; Saadatnia et al. 2020; Brouwer et al. 2018; Kara et al. 2015; Olaleye et al. 2014; Lin et al. 2004; Roderick et al. 2001; Baskett et al. 1999; Walker et al. 1999; Duncan et al. 1998; Widen Holmqvist et al. 1998; Young et al. 1992
2	Home rehabilitation, then Clinic rehabilitation may not have a difference in efficacy when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice for improving activities of daily living.	1	Hsieh et al. 2018
1a	Caregiver-Mediated Programs may produce greater improvements in activities of daily living than Conventional Care.	7	Deng et al. 2024; Wang et al. 2015; Mudzi et al. 2012; Galvin et al. 2011; Sackley et al. 2006; Mayo et al. 2000; Mant et al. 2000
1b	Nursing Mediated Program may produce greater improvements in activities of daily living than Conventional Care.	5	Chen et al. 2021a; Wang et al. 2021b; Zhang et al. 2021a; Zhang et al. 2018; Hui et al. 1995

2	Outpatient Clinic Care Follow-up may not have a difference in efficacy when compared to Conventional Control for improving activities of daily living.	1	Welin et al. 2010
1b	Specialist Community Rehabilitation may not have a difference in efficacy when compared to Conventional Rehabilitation for improving activities of daily living.	1	Rudd et al. 1997
2	Rapid rehabilitation nursing with continuous nursing after discharge may produce greater improvements in activities of daily living than Routine nursing.	1	Xie et al. 2021b
2	Programmed Nursing Intervention (Including health education, personalized functional exercise plans, restoration function training) may produce greater improvements in activities of daily living than routine rehabilitation training.	1	Yang et al. 2019
1b	Home based physical activity and walking training program may not have a difference in efficacy when compared to Conventional care for improving activities of daily living.	1	Dean et al. 2018
1b	Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care may not have a difference in efficacy when compared to Physical Activity with Usual physiotherapy for improving activities of daily living.	1	Wright et al. 2021
1b	Caregiver-mediated exercise program with e-health support with telerehabilitation may not have a difference in efficacy when compared to Conventional therapy for improving activities of daily living.	1	Vloothuis et al. 2019
1b	Nurse-organized, family caregiver delivered rehabilitation (supported by a custom- designed smartphone application) may not have a difference in efficacy when compared to Usual care for improving activities of daily living.	1	Zhou et al. 2019
1b	Caregiver-mediated iPad exercise program with FitBit activity monitor (real-time feedback) may not have a difference in efficacy when compared to Usual care for improving activities of daily living.	1	Van Den Berg et al. 2016
1b	Custom Occupational therapy with Caregiver training workshop may not have a difference in efficacy when compared to Usual care alone for improving activities of daily living.	1	Sackley et al. 2015

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home-Based Physiotherapy and Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving gait speed.	7	Salgueiro et al. 2022; Olaleye et al. 2014; Treger et al. 2014; Duncan et al. 2003; Baskett et al. 1999; Duncan et al. 1998; Widen Holmqvist et al. 1998
2	Home rehabilitation, then Clinic rehabilitation may not have a difference in efficacy when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice for improving gait speed.	1	Hsieh et al. 2018
1a	Caregiver-Mediated Programs may not have a difference in efficacy when compared to Conventional Care for improving gait speed.	2	Nordin et al. 2019; Wang et al. 2015
2	Nursing Mediated Program may produce greater improvements in gait speed than Conventional Care.	1	Chen et al. 2021a
1b	Home-based cycle ergometer exercise may not have a difference in efficacy when compared to Home-based overground walking exercise for improving gait speed.	1	Mayo et al. 2013

1b	Early Discharged At-Home Supported Training may not have a difference in efficacy when compared to Conventional Post-Discharge Rehabilitation for improving gait speed.	1	Askim et al. 2006
1b	Home-based isometric unilateral strength training with mirror therapy may not have a difference in efficacy when compared to Home-based isometric unilateral strength training for improving gait speed.	1	Simpson et al. 2019
1b	Caregiver-mediated exercise program with e-health support with telerehabilitation may not have a difference in efficacy when compared to Conventional therapy for improving gait speed.	1	Vloothuis et al. 2019
2	Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may produce greater improvements in gait speed than Botulinum Toxin A Injection.	1	Roche et al. 2015

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home-Based Physiotherapy and Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving gait endurance.	6	Guediri et al. 2022; Mandigout et al. 2021; Brouwer et al. 2018; Treger et al. 2014; Duncan et al. 2003; Duncan et al. 1998
1a	Caregiver-Mediated Programs may produce greater improvements in gait endurance than Conventional Care.	2	Wang et al. 2015; Galvin et al. 2011
1b	Home-based cycle ergometer exercise may not have a difference in efficacy when compared to Home-based overground walking exercise for improving gait endurance.	1	Mayo et al. 2013
1b	Active dual-hemispheric transcranial direct current stimulation with Home-based exercise may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Home-based exercise for improving gait endurance.	1	Prathum et al. 2022
1b	Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care may produce greater improvements in gait endurance than Physical Activity with Usual physiotherapy.	1	Wright et al. 2021
1b	Caregiver-mediated exercise program with e-health support with telerehabilitation may not have a difference in efficacy when compared to Conventional therapy for improving gait endurance.	1	Vloothuis et al. 2019
2	Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may not have a difference in efficacy when compared to Botulinum Toxin A Injection for improving gait endurance.	1	Roche et al. 2015

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home-Based Physiotherapy and Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving functional mobility.	11	Guediri et al. 2022; Mahmood et al. 2021; Mandigout et al. 2021; Brouwer et al. 2018; Malagoni et al. 2016; Kara et al. 2015; Olaleye et al. 2014; Treger et al. 2014; Lin et al. 2004; Roderick et al. 2001; Young et al. 1992
2	Home rehabilitation, then Clinic rehabilitation may produce greater improvements in functional mobility than Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice.	1	Hsieh et al. 2018

2	Home-based Oculomotor/Gaze Stability Exercises may produce greater improvements in functional mobility than Conventional Rehabilitation.	1	Correia et al. 2021
1a	Caregiver-Mediated Programs may not have a difference in efficacy when compared to Conventional Care for improving functional mobility.	5	Nordin et al. 2019; Mudzi et al. 2012; Sackley et al. 2006; Mayo et al. 2000; Mant et al. 2000
1b	Nursing Mediated Program may not have a difference in efficacy when compared to Conventional Care for improving functional mobility.	1	Jones et al. 2005
2	Rapid rehabilitation nursing with continuous nursing after discharge may produce greater improvements in functional mobility than Routine nursing.	1	Xie et al. 2021b
1b	Home based physical activity and walking training program may not have a difference in efficacy when compared to Conventional care for improving functional mobility.	1	Dean et al. 2018
1b	There is conflicting evidence about the effect of Augmented reality with home based exercise program when compared to Home based exercise program for improving functional mobility.	1	Lee et al. 2023d
1b	Active dual-hemispheric transcranial direct current stimulation with Home-based exercise may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Home-based exercise for improving functional mobility.	1	Prathum et al. 2022
1b	Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care may produce greater improvements in functional mobility than Physical Activity with Usual physiotherapy.	1	Wright et al. 2021
1b	Home-based isometric unilateral strength training with mirror therapy may not have a difference in efficacy when compared to Home-based isometric unilateral strength training for improving functional mobility.	1	Simpson et al. 2019
1b	Caregiver-mediated exercise program with e-health support with telerehabilitation may not have a difference in efficacy when compared to Conventional therapy for improving functional mobility.	1	Vloothuis et al. 2019
1b	There is conflicting evidence about the effect of Nurse-organized, family caregiver delivered rehabilitation (supported by a custom-designed smartphone application) when compared to Usual care for improving functional mobility.	1	Zhou et al. 2019
1b	Caregiver-mediated iPad exercise program with FitBit activity monitor (real-time feedback) may not have a difference in efficacy when compared to Usual care for improving functional mobility.	1	Van Den Berg et al. 2016
1b	Custom Occupational therapy with Caregiver training workshop may not have a difference in efficacy when compared to Usual care alone for improving functional mobility.	1	Sackley et al. 2015
2	Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may not have a difference in efficacy when compared to Botulinum Toxin A Injection for improving functional mobility.	1	Roche et al. 2015

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home-Based Physiotherapy and Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving balance.	7	Jarbandhan et al. 2022; Salgueiro et al. 2022; Brouwer et al. 2018; Olaleye et al. 2014; McClellan & Ada 2004; Duncan et al. 2003; Duncan et al. 1998

1a	Caregiver-Mediated Programs may produce greater improvements in balance than Conventional Care.	3	Nordin et al. 2019; Wang et al. 2015; Galvin et al. 2011
1b	Home-based cycle ergometer exercise may not have a difference in efficacy when compared to Home-based overground walking exercise for improving balance.	1	Mayo et al. 2013
1b	Early Discharged At-Home Supported Training may not have a difference in efficacy when compared to Conventional Post-Discharge Rehabilitation for improving balance.	1	Askim et al. 2006
1b	Augmented reality with home based exercise program may not have a difference in efficacy when compared to Home based exercise program for improving balance.	1	Lee et al. 2023d
1b	Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care may produce greater improvements in balance than Physical Activity with Usual physiotherapy.	1	Wright et al. 2021

Other Associated Outcome Measures

MOOD			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home-Based Physiotherapy and Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving mood.	2	Mandigout et al. 2021; Roderick et al. 2001
1b	Caregiver-Mediated Programs may not have a difference in efficacy when compared to Conventional Care for improving mood.	1	Mant et al. 2000
1b	Nursing Mediated Program may produce greater improvements in mood than Conventional Care.	2	Wang et al. 2021b; Zhang et al. 2021a
1b	Specialist Community Rehabilitation may not have a difference in efficacy when compared to Conventional Rehabilitation for improving mood.	1	Rudd et al. 1997
2	Rapid rehabilitation nursing with continuous nursing after discharge may produce greater improvements in mood than Routine nursing.	1	Xie et al. 2021b

1b	Augmented reality with home based exercise program may not have a difference in efficacy when compared to Home based exercise program for improving mood.	1	Lee et al. 2023d
1b	Caregiver-mediated exercise program with e-health support with telerehabilitation may not have a difference in efficacy when compared to Conventional therapy for improving mood.	1	Vloothuis et al. 2019
1b	Caregiver-mediated iPad exercise program with FitBit activity monitor (real-time feedback) may not have a difference in efficacy when compared to Usual care for improving mood.	1	Van Den Berg et al. 2016

FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Home-Based Physiotherapy and Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving fatigue and sleep.	1	Mandigout et al. 2021
1b	Home based physical activity and walking training program may not have a difference in efficacy when compared to Conventional care for improving fatigue and sleep.	1	Dean et al. 2018
1b	Caregiver-mediated exercise program with e-health support with telerehabilitation may not have a difference in efficacy when compared to Conventional therapy for improving fatigue and sleep.	1	Vloothuis et al. 2019
1b	Caregiver-mediated iPad exercise program with FitBit activity monitor (real-time feedback) may not have a difference in efficacy when compared to Usual care for improving fatigue and sleep.	1	Van Den Berg et al. 2016

COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Caregiver-Mediated Programs may not have a difference in efficacy when compared to Conventional Care for improving cognition.	1	Wang et al. 2015

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home-Based Physiotherapy and Exercise Programs may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving upper extremity function.	5	Jarbandhan et al. 2022; Duncan et al. 2003; Baskett et al. 1999; Duncan et al. 1998; Widen Holmqvist et al. 1998
2	There is conflicting evidence about the effect of Home rehabilitation, then Clinic rehabilitation when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice for improving upper extremity function.	1	Hsieh et al. 2018
1b	Caregiver-Mediated Programs may produce greater improvements in upper extremity function than Conventional Care.	1	Deng et al. 2024
1b	Nursing Mediated Program may not have a difference in efficacy when compared to Conventional Care for improving upper extremity function.	1	Jones et al. 2005
1b	Active dual-hemispheric transcranial direct current stimulation with Home-based exercise may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Home-based exercise for improving upper extremity function.	1	Prathum et al. 2022

Key Points

- Home-Based Physiotherapy and Exercise Programs may be beneficial for improving motor recovery, but not biomechanical gait measures, muscle strength, neurophysiological measures, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy or No Therapy; the literature is mixed regarding spasticity.
- Home rehabilitation, then Clinic rehabilitation may be beneficial for improving functional mobility, but not activities of daily living and gait speed, after stroke when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice; the literature is mixed regarding quality of life.
- Home-based Oculomotor/Gaze Stability Exercises may be beneficial for improving functional mobility, but not falls and fear of falling, after stroke when compared to Conventional Rehabilitation.
- Caregiver-Mediated Programs may be beneficial for improving motor recovery, spasticity, activities of daily living, gait endurance, balance, and quality of life, but not gait speed and functional mobility, after stroke when compared to Conventional Care.
- Nursing Mediated Program may be beneficial for improving motor recovery, spasticity, activities of daily living, gait speed, and quality of life, but not muscle strength and functional mobility, after stroke when compared to Conventional Care.
- Home-based cycle ergometer exercise may not be beneficial for improving gait speed, gait endurance, balance, and quality of life after stroke when compared to Home-based overground walking exercise.
- Early Discharged At-Home Supported Training may not be beneficial for improving gait speed and balance after stroke when compared to Conventional Post-Discharge Rehabilitation.
- Outpatient Clinic Care Follow-up may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional Control.
- Specialist Community Rehabilitation may not be beneficial for improving muscle strength, activities of daily living, and quality of life after stroke when compared to Conventional Rehabilitation.
- Rapid rehabilitation nursing with continuous nursing after discharge may be beneficial for improving activities of daily living, functional mobility, and quality of life after stroke when compared to Routine nursing.
- Programmed Nursing Intervention (Including health education, personalized functional exercise plans, restoration function training) may be beneficial for improving motor recovery, activities of daily living, and quality of life after stroke when compared to routine rehabilitation training.
- Home based physical activity and walking training program may not be beneficial for improving activities of daily living, functional mobility, and quality of life after stroke when compared to Conventional care.
- Augmented reality with home based exercise program may be beneficial for improving falls and fear of falling, but not balance and quality of life, after stroke when compared to Home based exercise program; the literature is mixed regarding functional mobility.
- Active dual-hemispheric transcranial direct current stimulation with Home-based exercise may not be beneficial for improving motor recovery, muscle strength, gait endurance, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with Home-based exercise.
- Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care may be beneficial for improving gait endurance, functional mobility, and balance, but not aerobic measures and activities of daily living, after stroke when compared to Physical Activity with Usual physiotherapy.
