- BASNEF model motivational training with home-based rehabilitation may be beneficial for improving motor recovery after stroke when compared to Conventional Care.
- Home-based isometric unilateral strength training with mirror therapy may not be beneficial for improving muscle strength, spasticity, gait speed, functional mobility, and quality of life after stroke when compared to Home-based isometric unilateral strength training.
- Caregiver-mediated exercise program with e-health support with telerehabilitation may not be beneficial for improving motor recovery, muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Conventional therapy.
- Nurse-organized, family caregiver delivered rehabilitation (supported by a custom- designed smartphone application) may not be beneficial for improving activities of daily living and quality of life after stroke when compared to Usual care; the literature is mixed regarding functional mobility.

- Caregiver-mediated iPad exercise program with FitBit activity monitor (real-time feedback) may not be beneficial for improving motor recovery, muscle strength, activities of daily living, functional mobility, balance, and quality of life after stroke when compared to Usual care.
- Custom Occupational therapy with Caregiver training workshop may not be beneficial for improving activities of daily living, functional mobility, and quality of life after stroke when compared to Usual care alone.
- Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may be beneficial for improving gait speed, but not spasticity, gait endurance, and functional mobility, after stroke when compared to Botulinum Toxin A Injection.

Summary of Key Points: Home-Based and Caregiver-Mediated Exercise Programs

Intervention	Control(s)	Function domain(s)	Effect
Home-Based Physiotherapy and Exercise Programs	Conventional Therapy or No Therapy	Motor recovery	+
Home-Based Physiotherapy and Exercise Programs	Conventional Therapy or No Therapy	Biomechanical gait measures, muscle strength, neurophysiological measures, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Home-Based Physiotherapy and Exercise Programs	Conventional Therapy or No Therapy	Spasticity	=
Home rehabilitation, then Clinic rehabilitation	Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice	Functional mobility	+
Home rehabilitation, then Clinic rehabilitation	Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice	Activities of daily living, gait speed	–
Home rehabilitation, then Clinic rehabilitation	Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice	Quality of life	=
Home-based Oculomotor/Gaze Stability Exercises	Conventional Rehabilitation	Functional mobility	+
Home-based Oculomotor/Gaze Stability Exercises	Conventional Rehabilitation	Falls and fear of falling	–
Caregiver-Mediated Programs	Conventional Care	Motor recovery, spasticity, activities of daily living, gait endurance, balance, quality of life	+
Caregiver-Mediated Programs	Conventional Care	Gait speed, functional mobility	–
Nursing Mediated Program	Conventional Care	Motor recovery, spasticity, activities of daily living, gait speed, quality of life	+
Nursing Mediated Program	Conventional Care	Muscle strength, functional mobility	–
Home-based cycle ergometer exercise	Home-based overground walking exercise	Gait speed, gait endurance, balance, quality of life	–
Early Discharged At-Home Supported Training	Conventional Post-Discharge Rehabilitation	Gait speed, balance	–
Outpatient Clinic Care Follow-up	Conventional Control	Motor recovery, activities of daily living	–

Specialist Community Rehabilitation	Conventional Rehabilitation	Muscle strength, activities of daily living, quality of life	−
Rapid rehabilitation nursing with continuous nursing after discharge	Routine nursing	Activities of daily living, functional mobility, quality of life	+
Programmed Nursing Intervention (Including health education, personalized functional exercise plans, restoration function training)	routine rehabilitation training	Motor recovery, activities of daily living, quality of life	+
Home based physical activity and walking training program	Conventional care	Activities of daily living, functional mobility, quality of life	−
Augmented reality with home based exercise program	Home based exercise program	Falls and fear of falling	+
Augmented reality with home based exercise program	Home based exercise program	Balance, quality of life	−
Augmented reality with home based exercise program	Home based exercise program	Functional mobility	=
Active dual-hemispheric transcranial direct current stimulation with Home-based exercise	Sham transcranial direct current stimulation with Home-based exercise	Motor recovery, muscle strength, gait endurance, functional mobility	−
BASNEF model motivational training with home-based rehabilitation	Conventional Care	Motor recovery	+
Home-based isometric unilateral strength training with mirror therapy	Home-based isometric unilateral strength training	Muscle strength, spasticity, gait speed, functional mobility, quality of life	−
Caregiver-mediated exercise program with e-health support with telerehabilitation	Conventional therapy	Motor recovery, muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance, quality of life	−
Nurse-organized, family caregiver delivered rehabilitation (supported by a custom- designed smartphone application)	Usual care	Activities of daily living, quality of life	−
Nurse-organized, family caregiver delivered rehabilitation (supported by a custom- designed smartphone application)	Usual care	Functional mobility	=
Caregiver-mediated iPad exercise program with FitBit activity monitor (real-time feedback)	Usual care	Motor recovery, muscle strength, activities of daily living, functional mobility, balance, quality of life	−
Custom Occupational therapy with Caregiver training workshop	Usual care alone	Activities of daily living, functional mobility, quality of life	−
Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy	Botulinum Toxin A Injection	Gait speed	+
Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy	Botulinum Toxin A Injection	Spasticity, gait endurance, functional mobility	−
Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care	Physical Activity with Usual physiotherapy	Aerobic measures, activities of daily living	−
Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care	Physical Activity with Usual physiotherapy	Gait endurance, functional mobility, balance	+

Telerehabilitation and Technology-Based Home Exercise Programs

Adopted from: https://unsplash.com/

Telerehabilitation is the process of providing rehabilitation services remotely through information and communication technologies (e.g. a kiosk, telephone and computer) (Dodakian et al., 2017; Emmerson et al., 2017). This rehabilitation method is particularly useful for patients who cannot access a rehabilitation center (Benvenuti et al., 2014). Additionally, this intervention can be delivered for a longer duration and at a reduced cost when compared to therapies provided in the inpatient rehabilitation setting (Benvenuti et al., 2014).

A total of 24 RCTs were found that evaluated telerehabilitation and Technology-Based home exercise programs for lower extremity motor rehabilitation. Fourteen RCTs compared Home Based Therapy Using Technology and Telerehabilitation with Conventional Therapy or No Therapy (Mulder et al. 2024; Wang et al. 2024c; Guo et al. 2023; Garcia et al. 2022; Lee et al. 2022c; Chen et al. 2021a; Lim et al. 2021; Saywell et al. 2021; Vahlberg et al. 2021; Chen et al. 2021b; Chung et al. 2020a; Wu et al. 2020b; Lin et al. 2014b; Ada et al. 2003). One RCT compared Telerehabilitation Computerized Complex Repetitive Ankle Movement Training with Simple Ankle Movement Training (Deng et al. 2012). Two RCTs compared Telerehabilitation Physiotherapy Combined with EMG-NMES with Conventional Therapy Combined with EMG-NMES (Chen et al. 2020b; Chen et al. 2017). Four RCTs compared Caregiver-Mediated Programs using Telerehabilitation or Technology with Conventional Care (Esteki-Ghashghaei et al. 2020; Vloothuis et al. 2019; Zhou et al. 2019; Van Den Berg et al. 2016). One RCT compared Video-Based Home Exercise Training with Paper-Based Home Exercise Training (Ozden et al. 2024).

In addition, one RCT in which telerehabilitation and Technology-Based home exercise programs formed part of a combined or comparative intervention are cross-referenced at the end of Table 25; their primary listings appear in other tables.

The methodological details and results of all 24 RCTs are presented in Table 25.

Table 25. RCTs Evaluating Telerehabilitation and Technology-Based Home Exercise Programs for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Home Based Therapy Using Technology and Telerehabilitation vs Conventional Therapy or No Therapy		
Mulder et al. (2024) RCT (5) Nstart=41 Nend=37 TPS=Subacute A vs 0 Also in Table 5 (Task-Specific Training)	E: Armed4Stroke (Task-specific Exercise Telerehabilitation Program) + Usual Care C: Usual Care Duration: E: 30min/day, 5x/wk, for 8wks, C: Usual Care for 8wks	E vs C: Stroke Impact Scale (SIS) Strength (+exp) Rivermead Mobility Index (RMI) (-) Functional Ambulation Categories (FAC) (-) Change Assessment Questionnaire (CAQ) 5-Metre Walk Test (5MWT) (-) 6-Minute Walk Test (6MWT) (-)

		Berg Balance Scale (BBS) (-) Motricity Index (MI) (-) Nottingham Extended ADL (NEADL) NEADL-Leisure (+exp) Modified Rankin Scale (mRS) (-) Transition Preparedness Scale (TPS) (-) Stroke Self-Efficacy Questionnaire (SSEQ) (-) General Self-Efficacy Scale (GSES) (-) EuroQol 5 Dimensions (EQ5D) (-) Fatigue Severity Scale (FSS) (-) Family Assessment Device-General Functioning (FAD-GF) (-) Hospital Anxiety and Depression Scale (HADS) Anxiety (-) Depression (-) Patient Reported Outcome Measurement Information System (PROMIS) (-) Caregiver Strain Index (CSI) (-) Carer-related Quality of Life Instrument (CarerQoL) (-) Preparedness for Caregiving Scale (PCS) (-).
Wang et al. (2024c) RCT (7) Nstart=80 Nend=80 TPS=Subacute A + B vs 0	E: Internet-based remote home rehabilitation + lower limb Wearable device training C: Conventional Care (Home-based rehabilitation) Duration: E: 60min/d, 6d/wk, 12 wks ; C: 90min(60 min conventional rehab + 30mins life ability training)/d, 6d/wk, 12 wks	E vs C: FMA (+exp) MAS (+exp) BBS (+exp) MBI (+exp) Hamilton Rating Scale for Depression (+exp) Gait Stride length (+exp) walking speed (+exp) cadence (+exp) Serum neurocytokine BDNF (+exp) NT-3 (+exp) NGF (+exp)

Garcia et al. (2022) Feasibility/pilot RCT (3) Nstart=10 Nend=6 TPS=Chronic A vs 0 Also in Table 26 (Virtual Reality)	E: Telerehabilitation video games C: Conventional rehab Duration: 30 min session/d, 3d/wk, 8 wks - 2wk washout	E vs C: VAS-pain(-) ROM(-) FIM(-) Berg(-) SF-36 PCS(-)
Lee et al. (2022c) Feasibility/pilot RCT (5)	E: Telerehab Dance procol + conventional therapy	E vs C: TIS(-)

Nstart=17 Nend=14 TPS=Subacute A vs 0	C: Conventional rehab Duration: 40min/d, 2d/wk, 3wks	K-MBI(-) BBS(-) TUG(-) FAC(-) EQ5D(-)
Chen et al. (2021b) RCT (5) Nstart=30 Nend=30 TPS=Chronic A vs 0 Also in Table 26 (Virtual Reality)	E: Telerehabilitation using a Kinect camera-based interactive telerehabilitation system C: Conventional physiotherapy Duration: 40min/d, 3d/wk, for 4wks	E vs C: Berg Balance Scale (-) Timed up and Go test (-) Modified Falls Efficacy Scale (-) Motricity Index (-) Functional Ambulation Category (-)
Lim et al. (2021) RCT (6) Nstart=17 Nend=17 TPS=Chronic A vs B	E: Coordination exercises at home and telehealth C: Conventional Clinic-based exercises Duration: 5d/wk, for 6wks	E vs C: 10-meter walk test Comfortable (-) Fast (-) Figure of 8 walk test Speed (+exp) Step (-) Four-square step test (-) SF-36 (-)
Saywell et al. (2021) RCT (7) Nstart=95 Nend=91 TPS=Chronic A vs 0	E: Augmented Community Telerehabilitation Intervention (4 face-to-face visits, 5 structured phone calls, personalized text messages) C: Usual care Duration: 6mo	E vs C: Stroke Impact scale physical (-) strength (-) memory (-) emotion (-) communication (-) activities of daily living (-) mobility (-) use of hand (-) participation (+exp) Grip strength affected side (-) unaffected side (-) Step test affected side (-) unaffected side (-) Stroke Self-efficacy Questionnaire (-) EuroQOL-5D-Visual Analogue Scale (+exp) Adverse events (-)
Vahlberg et al. (2021) RCT (7) Nstart=79 Nend=71 TPS=Acute A vs 0	E: Standard care and daily mobile-phone delivered training messages C: Standard care Duration: 12wks	E vs C: 6-minute walking test (+exp) 5 time chair-stand test (+exp) 10-metre walk test (-) Short Physical Performance Battery (-)
Chen et al. (2021a) RCT (5) Nstart=140 Nend=121	E: Nurse-guided home-based PT exercise program + conventional rehabilitation C: Conventional Rehabilitation Duration: 30min/session, 3d/wk for first 3mo, 1d/wk for second 3mo, 1d/mo for	E vs C: Fugl-Meyer assessment (+exp) Modified Ashworth Scale (+exp) 10-Meter Walk Test (+exp)

TPS=Subacute A vs 0 Also in Table 24 (Home-Based and Caregiver-Mediated Exercise Programs)	the rest up to 12mo, home-based exercise	Barthel Index (+exp)
Chung et al. (2020a) RCT (7) Nstart=60 Nend=56 TPS=Subacute A1 vs A2	E: Customized video-guided home-exercise C: Customized paper-based (pamphlet) home-exercise Duration: 10-30min/d, for 3mo	E vs C: Self-efficacy for exercise-Chinese version (+Exp) Modified Barthel index-Chinese version (-) Modified Functional Ambulatory category (+exp) Adherence to program (+exp)
Wu et al. (2020b) RCT (7) Nstart=64 Nend=61 TPS=Subacute A vs 0	E: Home remote rehabilitation based on a collaborative care model C: Routine rehabilitation Duration: 1-2d/wk, for 12wks	E vs C: Fugl-Meyer Motor Function Assessment (Upper and lower limb) (+exp) Berg Balance Scale (+exp) Timed “UP & GO” test (+exp) 6-minute walking test (+exp) Modified Barthel Index (+exp) Stroke-Specific Quality of Life Scale (+exp) Energy (+exp) Family Role (+exp) Language (+exp) Mobility (+exp) Mood (+exp) Personality (-) Selaf-care (+exp) Social role (+exp) Thinking (-) Upper Extremity (+exp) Vision (-) Work (+exp)
Lin et al. (2014b) RCT (7) Nstart=24 Nend=23 TPS=Chronic A vs 0	E: Telerehabilitation program C: Conventional therapy Duration: 50min/d, 3d/wk, for 4wks	E vs C: Berg Balance Scale (-) Barthel Index (-) Self-care (-) Mobility (-) Satisfaction with training (-)
Ada et al. (2003) RCT (7) Nstart=29 Nend=27 TPS=Chronic A vs B Also in Table 7 (Non-Technological Overground Walking and Gait Training); Table 9 (Treadmill Training)	E: Treadmill training and overground gait training C: Placebo program of low- intensity home exercise program + Telerehabilitation Duration: 30min/d, 3d/wk, for 4wks Treadmill and overground walking, 3d/wk, for 4wks Placebo program	E vs C: 6-Minute Walk Distance Test (+exp) 10-Metre Walk Speed Test (+exp) Stroke-adapted Sickness Impact Profile (SA-SIP30) (-) Step Length Affected Leg (+exp) Intact Leg (+exp) Step Width (-) Cadence (-)
Telerehabilitation Computerized Complex Repetitive Ankle Movement Training vs Simple Ankle Movement Training		
Deng et al. (2012) RCT (4) Nstart=19 Nend=16	E: Computerized complex repetitive ankle movement training C: Simple repetitive ankle movement training	E vs C: Paretic ankle Dorsiflexion during the swing phase of gait (+exp)

TPS=Chronic A1 vs A2	Duration: time-matched 60 training blocks/d, 20d over 4wks	Paretic ankle Plantarflexion during the swing phase of gait (-) 10-m walk test (-) Gait temporal symmetry ratio (-) Variance of toe clearance (-) Stride length (-) fMRI parameters (-)
Telerehabilitation Physiotherapy Combined with EMG-NMES vs Conventional Therapy Combined with EMG-NMES		
Chen et al. (2020b) RCT (7) Nstart=52 Nend=44 TPS=Acute A vs B	E: Telerehabilitation therapy (including PT, OT, ETNS guide by therapist over videocalls) C: In-person rehabilitation (including PT, OT, ETNS) Duration: 60min OT & PT + 20min ETNS/ session, 10d over 12wks.	E vs C: Fugl-Meyer Assessment (+exp) Modified Barthel Index (-)
Chen et al. (2017) RCT (8) Nstart=54 Nend=51 TPS=Acute A + B vs 0 Also in Table 29 (Neuromuscular Electrical Stimulation (NMES))	E: Tele-supervising rehabilitation (PT+ EMG-NMES) C: Conventional Care Duration: 1hr, 2x/d, 5d/wk, for 12 wks PT + 20min, 2x/d, 5d/wk, for 12wks	E vs C: modified Barthel Index(-) Berg Balance Scale(-) Caregiver Strain Index (-) Root mean square extensor carpi radialis longus (-) tibialis anterior (-)
Caregiver-Mediated Programs using Telerehabilitation or Technology vs Conventional Care		
Esteki-Ghashghaei et al. (2020) RCT (5) Nstart=57 Nend=40 TPS=Acute A + B vs 0 Also in Table 24 (Home-Based and Caregiver-Mediated Exercise Programs)	E: BASNEF model motivational training + home-based rehabilitation C: Conventional Care Duration: 3 sessions of training	E vs C: Fugl-Meyer Assessment (+exp) Questionnaire based on BASNEF model (+exp)
Vloothuis et al. (2019) RCT (8) Nstart=66 Nend=62 TPS=Subacute A + B vs 0 Also in Table 24 (Home-Based and Caregiver-Mediated Exercise Programs)	E: Caregiver-mediated exercise program with e-health support + telerehabilitation C: Conventional therapy Duration: 30min/d, 5d/wk for 8wks - Caregiver-mediated exercise program	E vs C: Stroke Impact Scale (-) Length of stay (-) Fugl-Meyer Assessment (-) Motricity Index (-) 6-Minute Walking Test (-) 10-Metre Walk Test (-) Timed Up & Go Test (-) Berg Balance Scale (-) Rivermead Mobility Index (-) Barthel Index (-) Nottingham Extended ADL scale (-) Modified Rankin Scale (-) Caregiver Strain Index (-) Carer Quality of Life Scale (-) Hospital Anxiety and Depression Scale Patient Anxiety (+exp) Patient Depression (-) Caregiver Anxiety (-) Caregiver Depression (+exp)

		Fatigue Severity Scale (-) General Self-Efficacy Scale (-)
Zhou et al. (2019) RCT (7) Nstart=246 Nend=244 TPS=Acute A vs 0 Also in Table 24 (Home-Based and Caregiver-Mediated Exercise Programs)	E: Nurse-organized, family caregiver delivered rehabilitation (supported by a custom- designed smartphone application) C: Usual care Duration: 15-30min/session, 2- 3d caregiver training sessions, outcome measured at 6mo	E vs C: Barthel index (-) Modified Rankin scale (-) Functional ambulation category (+con) Patient health questionnaire 9 (-) EuroQol-5-dimension (-) Caregiver burden index (-)
Van Den Berg et al. (2016) RCT (8) Nstart=63 Nend=60 TPS=Acute A + B vs 0 Also in Table 24 (Home-Based and Caregiver-Mediated Exercise Programs)	E: Caregiver-mediated iPad exercise program + FitBit activity monitor (real-time feedback) C: Usual care Duration: 30min/d, 5x/wk for 8wks Caregiver-mediated program	E vs C: Stroke Impact scale (-) Rivermead mobility index (-) Barthel index (-) Nottingham extended ADL (+exp) Timed Up and Go (-) 10m timed walk (-) Fugl-Meyer assessment-lower extremity (-) Motricity index (-) Berg Balance scale (-) Hospital anxiety and depression scale patient (-) caregiver (-) General Self-efficacy scale patient (-) caregiver (-) Fatigue severity scale patient (-) caregiver (-) Carer QOL (-) Caregiver strain index (-) Modified Rankin Scale (No stats)
Video-Based vs Paper-Based Home Exercise Training		
Ozden et al. (2024) RCT (7) Nstart=32 Nend=32 TPS=Chronic A vs B	E: Video based exercise training C: Paper based exercise training Duration: 2 times a day, 6wks	E vs C: Falls efficacy scale-international (-) Activities-Specific Balance Confidence Scale (+exp) Stroke self-efficacy questionnaire (+exp) telemedicine satisfaction questionnaire (no stat)
Additional Comparisons from the Source Dataset		
Grau-Pellicer et al. (2020) RCT (4) Nstart=41 Nend=34 TPS=Chronic A vs 0	E: Home based Multimodal rehabilitation program by mHealth app C: Conventional care Duration: E: 1h/d, 2d/wk, 8wk C: daily, 3m0	E vs C: Adherence to physical activity: Community ambulation min./day (+exp) Sitting time hours/day (+exp) 10m Walk test comfort(+exp) fast(+exp) 6min Walk test (+exp) Timed Up and Go (-) Barthel index (+exp) EuroQoL (+exp)

Lawrie et al. (2018) RCT (6) Nstart=30 Nend=24 TPS=Subacute A vs 0	E: Smart-watch feedback on daily activity level C: local routine treatment Duration: 2x/hr for the first 8hr, 1x/hr for the last 1hr feedback, 9hr/d, 3wks	E vs C: Montreal Cognitive Assessment (No stats) Barthel index (No stats) WHO Disability assessment scale-12 item (No stats) Fatigue severity scale (No stats) EuroQOL 5D-5L (No stats) Rivermead mobility index (No stats) Visual Analog Fatigue Scale (No stats) 10m Walk test (No stats) Grip strength (No stats)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Llorens et al. (2015b) RCT (8) Nstart=31 Nend=30 TPS=Chronic A1 vs A2 Primary listing: Table 26 (Virtual Reality)	E: Virtual reality-based telerehabilitation in Home + conventional physical therapy C: Virtual reality-based rehabilitation in clinic + conventional physical therapy Duration: 45min/d, 3d/wk, for 7wks (20 total session)	E vs C: Brunel Balance Assessment (-) Berg Balance Scale (-) Tinetti Performance-Oriented Mobility Assessment (-) System Usability Scale (-) Intrinsic Motivation Inventory (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home Based Therapy Using Technology and Telerehabilitation may produce greater improvements in motor recovery than Conventional Therapy or No Therapy.	4	Wang et al. 2024c; Guo et al. 2023; Chen et al. 2021a; Wu et al. 2020b
1b	Telerehabilitation Physiotherapy Combined with electromyography-neuromuscular electrical stimulation may produce greater improvements in motor recovery than Conventional Therapy Combined with electromyography-neuromuscular electrical stimulation.	1	Chen et al. 2020b
1a	There is conflicting evidence about the effect of Caregiver-Mediated Programs using Telerehabilitation or Technology when compared to Conventional Care for improving motor recovery.	3	Esteki-Ghashghaei et al. 2020; Vloothuis et al. 2019; Van Den Berg et al. 2016

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home Based Therapy Using Technology and Telerehabilitation may produce greater improvements in biomechanical gait measures than Conventional Therapy or No Therapy.	2	Wang et al. 2024c; Ada et al. 2003
2	Telerehabilitation Computerized Complex Repetitive Ankle Movement Training may not have a difference in efficacy when	1	Deng et al. 2012

	compared to Simple Ankle Movement Training for improving biomechanical gait measures.		

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Home Based Therapy Using Technology and Telerehabilitation may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving muscle strength.	2	Mulder et al. 2024; Chen et al. 2021b
1a	Caregiver-Mediated Programs using Telerehabilitation or Technology may not have a difference in efficacy when compared to Conventional Care for improving muscle strength.	2	Vloothuis et al. 2019; Van Den Berg et al. 2016

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Home Based Therapy Using Technology and Telerehabilitation may produce greater improvements in spasticity than Conventional Therapy or No Therapy.	2	Wang et al. 2024c; Chen et al. 2021a

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Home Based Therapy Using Technology and Telerehabilitation may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving range of motion.	1	Garcia et al. 2022

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Home Based Therapy Using Technology and Telerehabilitation may produce greater improvements in neurophysiological measures than Conventional Therapy or No Therapy.	1	Wang et al. 2024c
2	Telerehabilitation Computerized Complex Repetitive Ankle Movement Training may not have a difference in efficacy when compared to Simple Ankle Movement Training for improving neurophysiological measures.	1	Deng et al. 2012

PAIN			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Home Based Therapy Using Technology and Telerehabilitation may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving pain.	1	Garcia et al. 2022

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home Based Therapy Using Technology and Telerehabilitation may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving activities of daily living.	7	Mulder et al. 2024; Wang et al. 2024c; Garcia et al. 2022; Saywell et al. 2021; Chen et al. 2021a; Wu et al. 2020b; Lin et al. 2014b

1a	Telerehabilitation Physiotherapy Combined with electromyography-neuromuscular electrical stimulation may not have a difference in efficacy when compared to Conventional Therapy Combined with electromyography-neuromuscular electrical stimulation for improving activities of daily living.	2	Chen et al. 2020b; Chen et al. 2017
1a	Caregiver-Mediated Programs using Telerehabilitation or Technology may not have a difference in efficacy when compared to Conventional Care for improving activities of daily living.	3	Vloothuis et al. 2019; Zhou et al. 2019; Van Den Berg et al. 2016
1b	Video-Based Home Exercise Training may produce greater improvements in activities of daily living than Paper-Based Home Exercise Training.	1	Ozden et al. 2024
2	Home based Multimodal rehabilitation program by mHealth app may produce greater improvements in activities of daily living than Conventional care.	1	Grau-Pellicer et al. 2020
1b	Smart-watch feedback on daily activity level may not have a difference in efficacy when compared to local routine treatment for improving activities of daily living.	1	Lawrie et al. 2018

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Home Based Therapy Using Technology and Telerehabilitation may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving gait speed.	6	Mulder et al. 2024; Wang et al. 2024c; Lim et al. 2021; Vahlberg et al. 2021; Chen et al. 2021a; Ada et al. 2003
2	Telerehabilitation Computerized Complex Repetitive Ankle Movement Training may not have a difference in efficacy when compared to Simple Ankle Movement Training for improving gait speed.	1	Deng et al. 2012

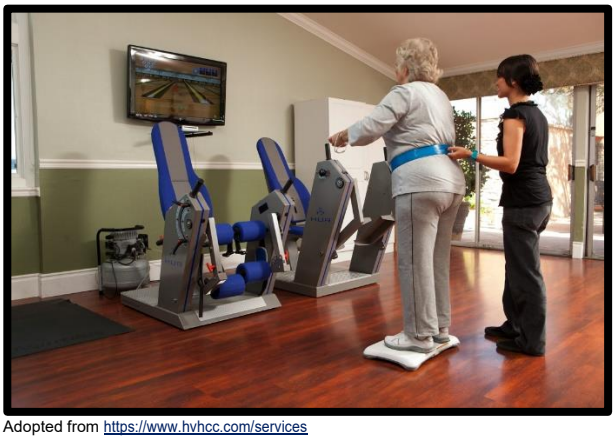
UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Home Based Therapy Using Technology and Telerehabilitation may not have a difference in efficacy when compared to Conventional Therapy or No Therapy for improving upper extremity function.	1	Saywell et al. 2021
1b	Telerehabilitation Physiotherapy Combined with electromyography-neuromuscular electrical stimulation may not have a difference in efficacy when compared to Conventional Therapy Combined with electromyography-neuromuscular electrical stimulation for improving upper extremity function.	1	Chen et al. 2017
1b	Smart-watch feedback on daily activity level may not have a difference in efficacy when compared to local routine treatment for improving upper extremity function.	1	Lawrie et al. 2018

Key Points



- Home Based Therapy Using Technology and Telerehabilitation may be beneficial for improving motor recovery, biomechanical gait measures, spasticity, neurophysiological measures, and gait endurance, but not muscle strength, range of motion, pain, activities of daily living, gait speed, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy or No Therapy.
- Telerehabilitation Computerized Complex Repetitive Ankle Movement Training may not be beneficial for improving biomechanical gait measures, neurophysiological measures, and gait speed after stroke when compared to Simple Ankle Movement Training.
- Telerehabilitation Physiotherapy Combined with electromyography-neuromuscular electrical stimulation may be beneficial for improving motor recovery, but not activities of daily living, balance, and quality of life, after stroke when compared to Conventional Therapy Combined with electromyography-neuromuscular electrical stimulation.
- Caregiver-Mediated Programs using Telerehabilitation or Technology may not be beneficial for improving muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Conventional Care; the literature is mixed regarding motor recovery.
- Video-Based Home Exercise Training may be beneficial for improving activities of daily living after stroke when compared to Paper-Based Home Exercise Training; the literature is mixed regarding falls and fear of falling.
- Home based Multimodal rehabilitation program by mHealth app may be beneficial for improving activities of daily living, gait speed, gait endurance, and quality of life, but not functional mobility, after stroke when compared to Conventional care.
- Smart-watch feedback on daily activity level may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to local routine treatment.
- Virtual reality-based telerehabilitation in Home with conventional physical therapy may not be beneficial for improving functional mobility and balance after stroke when compared to Virtual reality-based rehabilitation in clinic with conventional physical therapy.

Summary of Key Points: Telerehabilitation and Technology-Based Home Exercise Programs

Intervention	Control(s)	Function domain(s)	Effect
Home Based Therapy Using Technology and Telerehabilitation	Conventional Therapy or No Therapy	Motor recovery, biomechanical gait measures, spasticity, neurophysiological measures, gait endurance	+
Home Based Therapy Using Technology and Telerehabilitation	Conventional Therapy or No Therapy	Muscle strength, range of motion, pain, activities of daily living, gait speed,	–

		functional mobility, balance, falls and fear of falling, quality of life	
Telerehabilitation Computerized Complex Repetitive Ankle Movement Training	Simple Ankle Movement Training	Biomechanical gait measures, neurophysiological measures, gait speed	−
Telerehabilitation Physiotherapy Combined with electromyography-neuromuscular electrical stimulation	Conventional Therapy Combined with electromyography-neuromuscular electrical stimulation	Motor recovery	+
Telerehabilitation Physiotherapy Combined with electromyography-neuromuscular electrical stimulation	Conventional Therapy Combined with electromyography-neuromuscular electrical stimulation	Activities of daily living, balance, quality of life	−
Caregiver-Mediated Programs using Telerehabilitation or Technology	Conventional Care	Muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance, quality of life	−
Caregiver-Mediated Programs using Telerehabilitation or Technology	Conventional Care	Motor recovery	=
Video-Based Home Exercise Training	Paper-Based Home Exercise Training	Activities of daily living	+
Video-Based Home Exercise Training	Paper-Based Home Exercise Training	Falls and fear of falling	=
Home based Multimodal rehabilitation program by mHealth app	Conventional care	Activities of daily living, gait speed, gait endurance, quality of life	+
Home based Multimodal rehabilitation program by mHealth app	Conventional care	Functional mobility	−
Smart-watch feedback on daily activity level	local routine treatment	Activities of daily living, gait speed, functional mobility, quality of life	−
Virtual reality-based telerehabilitation in Home with conventional physical therapy	Virtual reality-based rehabilitation in clinic with conventional physical therapy	Functional mobility, balance	−

Virtual Reality

Adopted from https://www.hvhcc.com/services

Virtual reality (VR) is a technology that allows individuals to experience and interact with virtual environments, often through a game. VR simulates life-like learning and can be used to increase intensity of training while providing three-dimensional feedback of a visual, sensory, and auditory nature (Saposnik et al., 2010).

VR tools are classified as either immersive (i.e. three-dimensional environment via head-mounted display) or non-immersive (i.e. two-dimensional environment via conventional computer monitor or projector screen). Customized VR programs have been created and tested in rehabilitation research, although commercial gaming consoles (e.g. Nintendo Wii) have also been used to deliver VR training.

A total of 86 RCTs were found that evaluated virtual reality for lower extremity motor rehabilitation. 41 RCTs compared Virtual Reality with Conventional Therapy or No Treatment (Kwak et al. 2024; Fahmy et al. 2024; Kilinc et al. 2023; Pelaez-Velez et al. 2023; Bai et al. 2022; Bian et al. 2022; Yaman et al. 2022; Marques-Sule et al. 2021; Anwar et al. 2021; Junata et al. 2021; Cano-Manas et al. 2020; Lin et al. 2020; Sheehy et al. 2020; Henrique et al. 2019; Hsieh et al. 2019b; Miranda et al. 2019; Utkan Karasu et al. 2018; Lee et al. 2018a; Choi et al. 2017a; Hung et al. 2017; James et al. 2017; Lee et al. 2017d; Park et al. 2017c; Pedreira da Fonseca 2017b; Hung et al. 2016b; In et al. 2016; Şimşek & Cekok 2016; Bower et al. 2015; Da Silva Ribeiro et al. 2015; Llorens et al. 2015a; Hung et al. 2014; Morone et al. 2014; Lee et al. 2014b; Barcala et al. 2013; Fritz et al. 2013; Rajaratnam et al. 2013; Cho et al. 2012; Kim et al. 2012c; Lee et al. 2012; Kim et al. 2009; You et al. 2005). Six RCTs compared Virtual Reality with Balance Training (Bashir et al. 2024; Zhang et al. 2020; James et al. 2017; Braun et al. 2016; Yatar et al. 2015; Jung et al. 2011). Five RCTs compared Virtual Reality Exercise Program with Exercise Program (Lee et al. 2023d; Arshad et al. 2022; Yang et al. 2022; Cannell et al. 2018; Chung et al. 2014). One RCT compared Virtual Reality Training with Treadmill Training (Bang et al. 2016a). Ten RCTs compared Virtual Reality with Treadmill Training with Conventional Therapy or Treadmill Training (Yang et al. 2024a; De Rooij et al. 2021; Kim et al. 2016c; Kim et al. 2015a; Cho et al. 2014; Cho et al. 2013c; Jung et al. 2012; Kang et al. 2012; Yang et al. 2011; Yang et al. 2008). Two RCTs compared Virtual Reality with Treadmill Training with Overground Gait Training (Wang et al. 2024e; Jaffe et al. 2004). Four RCTs compared Virtual Reality Robotic Training with Robotic Training and Conventional Therapy (Kayabinar et al. 2021; Bergmann et al. 2018b; Calabro et al. 2017; Mirelman et al. 2009). One RCT compared Virtual Reality Robotic Training with Robotic Training, Auditory Stimulation, and Conventional Therapy (Park et al. 2018a). Ten RCTs evaluated Virtual Reality with Other Modalities (Aslam et al. 2021; Malik et al. 2021; Miclaus et al. 2021; Tollar et al. 2021; dos Santos Junior et al. 2019; Forrester et al. 2016; Llorens et al. 2015b; Yom et al. 2015; Bower et al. 2014; McEwen et al. 2014). Three RCTs compared Brain-Computer Interface Controlled Training with Sham (Zhao et al. 2022c; Li et al. 2021a; Yuan et al. 2021). One RCT compared Virtual Reality Training with Strength and Resistance Training (Sultan et al. 2023).

In addition, 20 RCTs in which virtual reality formed part of a combined or comparative intervention are cross-referenced at the end of Table 26; their primary listings appear in other tables.

The methodological details and results of all 86 RCTs are presented in Table 26.

Table 26. RCTs Evaluating Virtual Reality for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Virtual Reality vs Conventional Therapy or No Treatment		
Kwak et al. (2024) Feasibility/pilot RCT (4) Nstart=44 Nend=36 TPS=Chronic A vs 0	E: FIVR (fully immersive virtual reality device) + conventional physical therapy C: Conventional physical therapy Duration: E: VR device 30 min/d, 3d/wk, 5 wks + physical therapy 30 min/d, 5d/wk, 5 wks ; C: physical therapy 30 min/day, 5d/wk, 5 wks	E vs C: Berg Balance Scale (-) TUG (+exp) gait speed (+exp) step length (+exp) stride length (+exp) single support time (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Virtual Reality may not have a difference in efficacy when compared to Conventional Therapy or No Treatment for improving muscle strength.	3	Lin et al. 2020; Hung et al. 2016b; Lee et al. 2012
2	Virtual Reality Robotic Training may not have a difference in efficacy when compared to Robotic Training and Conventional Therapy for improving muscle strength.	1	Bergmann et al. 2018b
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may produce greater improvements in muscle strength than Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.	1	Park et al. 2018a
1b	Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy or Auditory stimulation with robot-assisted gait training (Treadmill) with conventional physical therapy may produce greater improvements in muscle strength than Conventional physical therapy with treadmill training.	1	Park et al. 2018a

1b	Repetitive transcranial magnetic stimulation with Augmented reality gait adaptive training may not have a difference in efficacy when compared to Augmented reality gait adaptive training for improving muscle strength.	1	Fang et al. 2024
2	Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy may produce greater improvements in muscle strength than Sit-to-stand Training with physiotherapy.	1	Hyun et al. 2021
2	Telerehabilitation using a Kinect camera-based interactive telerehabilitation system may not have a difference in efficacy when compared to Conventional physiotherapy for improving muscle strength.	1	Chen et al. 2021b

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Virtual Reality may not have a difference in efficacy when compared to Conventional Therapy or No Treatment for improving spasticity.	2	Kilinc et al. 2023; Pelaez-Velez et al. 2023
1b	Virtual Reality Robotic Training may not have a difference in efficacy when compared to Robotic Training and Conventional Therapy for improving spasticity.	1	Calabrò et al. 2017
1b	Virtual reality therapy and mirror therapy (MT) exercises may not have a difference in efficacy when compared to lower extremity rehabilitation for improving spasticity.	1	Miclaus et al. 2021
1b	Virtual Reality with Other Modalities may produce greater improvements in spasticity than Task-specific training.	1	Yom et al. 2015
1b	Robotic-assisted gait training (Lokomat-Pro) with VR may not have a difference in efficacy when compared to Robotic-assisted gait training (Lokomat-Nanos) for improving spasticity.	1	Calabro et al. 2017

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Virtual Reality when compared to Conventional Therapy or No Treatment for improving range of motion.	1	James et al. 2017
1b	Virtual reality therapy and mirror therapy (MT) exercises may produce greater improvements in range of motion than lower extremity rehabilitation.	1	Miclaus et al. 2021
2	Treadmill training with Virtual reality and Ankle robotics may not have a difference in efficacy when compared to Seated training with Virtual reality and Ankle robotics for improving range of motion.	1	Forrester et al. 2016
2	Telerehabilitation video games may not have a difference in efficacy when compared to Conventional rehab for improving range of motion.	1	Garcia et al. 2022

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Virtual Reality may not have a difference in efficacy when compared to Conventional Therapy or No Treatment for improving neurophysiological measures.	1	Junata et al. 2021
1b	Virtual Reality Robotic Training may produce greater improvements in neurophysiological measures than Robotic Training and Conventional Therapy.	1	Calabrò et al. 2017

1b	Brain-Computer Interface Controlled Training may not have a difference in efficacy when compared to Sham for improving neurophysiological measures.	2	Zhao et al. 2022c; Li et al. 2021a
1b	Repetitive transcranial magnetic stimulation with Augmented reality gait adaptive training may not have a difference in efficacy when compared to Augmented reality gait adaptive training for improving neurophysiological measures.	1	Fang et al. 2024
1b	Robotic-assisted gait training (Lokomat-Pro) with VR may produce greater improvements in neurophysiological measures than Robotic-assisted gait training (Lokomat-Nanos).	1	Calabro et al. 2017

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	One session daily high intensity Videogame exercises with medical massage may result in lesser improvements in aerobic measures when compared to two sessions daily high intensity Videogame exercises with medical massage.	1	Tollar et al. 2021
1b	Virtual Reality with Other Modalities may not have a difference in efficacy when compared to Task-specific training for improving aerobic measures.	1	Tollar et al. 2021

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Virtual Reality may produce greater improvements in sensory and proprioceptive function than Conventional Therapy or No Treatment.	1	Hung et al. 2016b
1b	Virtual Reality may not have a difference in efficacy when compared to Proprioceptive Neuromuscular Facilitation for improving sensory and proprioceptive function.	1	dos Santos Junior et al. 2019
1b	Anodal Cerebellar tDCS with Xbox Kinect games or Anodal M1 tDCS with Xbox Kinect games may produce greater improvements in sensory and proprioceptive function than Sham Stimulation Group with Xbox Kinect games.	1	Qurat-ul-ain et al. 2022
1b	Anodal Cerebellar tDCS with Xbox Kinect games may not have a difference in efficacy when compared to Anodal M1 tDCS with Xbox Kinect games for improving sensory and proprioceptive function.	1	Qurat-ul-ain et al. 2022
1b	Virtual Reality or Virtual Reality with Proprioceptive Neuromuscular Facilitation may not have a difference in efficacy when compared to Proprioceptive Neuromuscular Facilitation for improving sensory and proprioceptive function.	1	Dos Santos Junior et al. 2019

PAIN			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Virtual Reality may not have a difference in efficacy when compared to Conventional Therapy or No Treatment for improving pain.	2	Cano-Manas et al. 2020; Da Silva Ribeiro et al. 2015
2	Telerehabilitation video games may not have a difference in efficacy when compared to Conventional rehab for improving pain.	1	Garcia et al. 2022

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Virtual Reality may not have a difference in efficacy when compared to Conventional Therapy or No Treatment for improving activities of daily living.	17	Fahmy et al. 2024; Kilinc et al. 2023; Bai et al. 2022; Marques-Sule et al. 2021; Junata et al. 2021; Cano-Manas et al. 2020; Lin et al. 2020; Utkan Karasu et al. 2018; Lee et al. 2017d; Şimşek & Cekok 2016; Bower et al. 2015; Hung et al. 2014; Morone et al. 2014; Barcala et al. 2013; Rajaratnam et al. 2013; Kim et al. 2012c; Lee et al. 2012
1b	Virtual Reality may produce greater improvements in activities of daily living than Balance Training.	3	Zhang et al. 2020; Braun et al. 2016; Yatar et al. 2015
2	Virtual Reality with Treadmill Training may not have a difference in efficacy when compared to Overground Gait Training for improving activities of daily living.	1	Wang et al. 2024e
1b	Virtual Reality Robotic Training may not have a difference in efficacy when compared to Robotic Training and Conventional Therapy for improving activities of daily living.	1	Kayabinar et al. 2021
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may not have a difference in efficacy when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy for improving activities of daily living.	1	Park et al. 2018a
1b	Virtual Reality Robotic Training may not have a difference in efficacy when compared to Robotic Training, Auditory Stimulation, and Conventional Therapy for improving activities of daily living.	1	Park et al. 2018a
1b	Virtual reality therapy and mirror therapy (MT) exercises may not have a difference in efficacy when compared to lower extremity rehabilitation for improving activities of daily living.	1	Miclaus et al. 2021
1b	Virtual Reality with Other Modalities may not have a difference in efficacy when compared to Task-specific training for improving activities of daily living.	1	Tollar et al. 2021
1b	One session daily high intensity Videogame exercises with medical massage may produce greater improvements in activities of daily living than Standard physical therapy with medical massage.	1	Tollar et al. 2021
1b	Two sessions daily high intensity Videogame exercises with medical massage may not have a difference in efficacy when compared to Standard physical therapy with medical massage for improving activities of daily living.	1	Tollar et al. 2021
2	Brain-Computer Interface Controlled Training may not have a difference in efficacy when compared to Sham for improving activities of daily living.	1	Zhao et al. 2022c
1b	Virtual Reality Training may produce greater improvements in activities of daily living than Strength and Resistance Training.	1	Sultan et al. 2023
2	Telerehabilitation video games may not have a difference in efficacy when compared to Conventional rehab for improving activities of daily living.	1	Garcia et al. 2022

2	Treadmill-based with augmented reality may not have a difference in efficacy when compared to Overground walking with physical obstacles for improving activities of daily living.	1	Timmermans et al. 2021
1b	Virtual reality augmented robot-assisted gait training with conventional care may not have a difference in efficacy when compared to Robot-assisted gait training with conventional care for improving activities of daily living.	1	Kayabinar et al. 2021

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Virtual Reality may produce greater improvements in gait speed than Conventional Therapy or No Treatment.	14	Kwak et al. 2024; Fahmy et al. 2024; Bai et al. 2022; Bian et al. 2022; Yaman et al. 2022; Hsieh et al. 2019b; Lee et al. 2018a; Choi et al. 2017a; Park et al. 2017c; In et al. 2016; Morone et al. 2014; Lee et al. 2014b; Fritz et al. 2013; Kim et al. 2009
1b	Game-based constraint-induced movement therapy with Traditional physical therapy may not have a difference in efficacy when compared to General game-based training with Traditional physical therapy for improving gait speed.	1	Choi et al. 2017a
2	Virtual Reality may not have a difference in efficacy when compared to Balance Training for improving gait speed.	1	Jung et al. 2011
1b	There is conflicting evidence about the effect of Virtual Reality Exercise Program when compared to Exercise Program for improving gait speed.	2	Cannell et al. 2018; Chung et al. 2014
1a	Virtual Reality with Treadmill Training may produce greater improvements in gait speed than Conventional Therapy or Treadmill Training.	6	Yang et al. 2024a; Kim et al. 2016c; Cho et al. 2014; Cho et al. 2013c; Kang et al. 2012; Yang et al. 2008
1b	Virtual reality treadmill training-based community ambulation may not have a difference in efficacy when compared to Community ambulation training for improving gait speed.	1	Kim et al. 2016c
1b	Treadmill with optic flow with conventional physical therapy may produce greater improvements in gait speed than Treadmill with conventional physical therapy.	1	Kang et al. 2012
2	Virtual Reality with Treadmill Training may produce greater improvements in gait speed than Overground Gait Training.	1	Wang et al. 2024e
1b	Virtual Reality Robotic Training may not have a difference in efficacy when compared to Robotic Training and Conventional Therapy for improving gait speed.	3	Kayabinar et al. 2021; Bergmann et al. 2018b; Mirelman et al. 2009
1b	There is conflicting evidence about the effect of Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy for improving gait speed.	1	Park et al. 2018a
1b	Virtual Reality Robotic Training may produce greater improvements in gait speed than Robotic Training, Auditory Stimulation, and Conventional Therapy.	1	Park et al. 2018a
2	Treadmill training with Virtual reality and Ankle robotics may not have a difference in efficacy when compared to Seated training with Virtual reality and Ankle robotics for improving gait speed.	1	Forrester et al. 2016

1b	Virtual Reality with Other Modalities may produce greater improvements in gait speed than Task-specific training.	1	Yom et al. 2015
1b	Group Video game therapy may not have a difference in efficacy when compared to Conventional care for improving gait speed.	1	Givon et al. 2016
1b	Peripheral nerve mobilization with virtual reality-based gait training may produce greater improvements in gait speed than Conventional exercises.	1	Vishnuram et al. 2024
1b	Motor imagery with virtual reality training may produce greater improvements in gait speed than virtual reality training with Conventional therapy.	1	Masood et al. 2024
1b	Repetitive transcranial magnetic stimulation with Augmented reality gait adaptive training may produce greater improvements in gait speed than Augmented reality gait adaptive training.	1	Fang et al. 2024
2	Selfpaced treadmill walking in virtual reality environment may produce greater improvements in gait speed than Self Placed Overground Platform walking.	1	Van Bladel et al. 2023
1b	There is conflicting evidence about the effect of Lokomat endurance video games when compared to Conventional Physiotherapy for improving gait speed.	1	Akinci et al. 2023
1b	Self paced treadmill walking in virtual reality environment may produce greater improvements in gait speed than Fixed speed treadmill walking in virtual reality environment.	1	Van Bladel et al. 2022
2	Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy may produce greater improvements in gait speed than Sit-to-stand Training with physiotherapy.	1	Hyun et al. 2021
2	Treadmill-based with augmented reality may not have a difference in efficacy when compared to Overground walking with physical obstacles for improving gait speed.	1	Timmermans et al. 2021
1b	Virtual reality augmented robot-assisted gait training with conventional care may not have a difference in efficacy when compared to Robot-assisted gait training with conventional care for improving gait speed.	1	Kayabinar et al. 2021
1b	Speed-Interactive Pedaling Training with Virtual Reality may produce greater improvements in gait speed than Pedaling Training.	1	Lee 2019d
2	Cognitive motor exergaming training may not have a difference in efficacy when compared to Conventional training (stretching, strengthening, balance and endurance training) for improving gait speed.	1	Kannan et al. 2019
1b	Dual-task (virtual reality-based UL training while walking on treadmill) may produce greater improvements in gait speed than Single task treadmill walking.	1	Fishbein et al. 2019
1b	There is conflicting evidence about the effect of Virtual reality with cognitive load with conventional rehabilitation when compared to Treadmill walking with virtual environment with conventional rehabilitation for improving gait speed.	1	Cho et al. 2015b
1b	Virtual walking training (virtual reality) with rehabilitation program may produce greater improvements in gait speed than Treadmill gait training with rehabilitation.	1	Cho et al. 2013c
1b	Xbox training during anodal tDCS stimulation to cerebellum may produce greater improvements in gait speed than Sham tDCS with xbox training.	1	Qurat-Ul-Ain et al. 2023
1b	Xbox training during nodal tDCS stimulation to motor cortex may not have a difference in efficacy when compared to Sham tDCS with xbox training for improving gait speed.	1	Qurat-Ul-Ain et al. 2023

1b	Xbox training during anodal tDCS stimulation to cerebellum may not have a difference in efficacy when compared to Xbox training during nodal tDCS stimulation to motor cortex for improving gait speed.	1	Qurat-Ul-Ain et al. 2023
1b	Anodal Cerebellar tDCS with Xbox Kinect games or Anodal M1 tDCS with Xbox Kinect games may not have a difference in efficacy when compared to Sham Stimulation Group with Xbox Kinect games for improving gait speed.	1	Qurat-ul-ain et al. 2022
1b	Anodal Cerebellar tDCS with Xbox Kinect games may not have a difference in efficacy when compared to Anodal M1 tDCS with Xbox Kinect games for improving gait speed.	1	Qurat-ul-ain et al. 2022

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Virtual Reality may not have a difference in efficacy when compared to Conventional Therapy or No Treatment for improving gait endurance.	3	Fahmy et al. 2024; Bower et al. 2015; Fritz et al. 2013
1a	Virtual Reality with Treadmill Training may not have a difference in efficacy when compared to Conventional Therapy or Treadmill Training for improving gait endurance.	3	De Rooij et al. 2021; Kim et al. 2016c; Kang et al. 2012
1b	Virtual reality treadmill training-based community ambulation may not have a difference in efficacy when compared to Community ambulation training for improving gait endurance.	1	Kim et al. 2016c

1b	Anodal Cerebellar tDCS with Xbox Kinect games may produce greater improvements in cognition than Anodal M1 tDCS with Xbox Kinect games.	1	Qurat-ul-ain et al. 2022

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Virtual Reality may not have a difference in efficacy when compared to Conventional Therapy or No Treatment for improving upper extremity function.	6	Kilinc et al. 2023; Bai et al. 2022; Lin et al. 2020; Sheehy et al. 2020; Henrique et al. 2019; Lee et al. 2018a
1b	Virtual Reality Exercise Program may not have a difference in efficacy when compared to Exercise Program for improving upper extremity function.	1	Yang et al. 2022
1b	Group Video game therapy may not have a difference in efficacy when compared to Conventional care for improving upper extremity function.	1	Givon et al. 2016

Key Points

- Virtual Reality may be beneficial for improving sensory and proprioceptive function, gait speed, and functional mobility, but not motor recovery, biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, neurophysiological measures, pain, activities of daily living, gait endurance, balance, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy or No Treatment; the literature is mixed regarding range of motion.
- Game-based constraint-induced movement therapy with Traditional physical therapy may be beneficial for improving biomechanical gait measures and biomechanical balance measures, but not gait speed, functional mobility, and balance, after stroke when compared to General game-based training with Traditional physical therapy.
- Virtual Reality may be beneficial for improving activities of daily living and functional mobility, but not gait speed, balance, and falls and fear of falling, after stroke when compared to Balance Training.
- Virtual Reality Exercise Program may be beneficial for improving falls and fear of falling, but not motor recovery, biomechanical gait measures, functional mobility, balance, and quality of life, after stroke when compared to Exercise Program; the literature is mixed regarding gait speed.
- Virtual Reality Training may not be beneficial for improving biomechanical gait measures after stroke when compared to Treadmill Training; the literature is mixed regarding biomechanical balance measures.
- Virtual Reality with Treadmill Training may be beneficial for improving gait speed, balance, and falls and fear of falling, but not biomechanical gait measures, biomechanical balance measures, gait endurance, functional mobility, and quality of life, after stroke when compared to Conventional Therapy or Treadmill Training.
- Virtual reality treadmill training-based community ambulation may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and falls and fear of falling after stroke when compared to Community ambulation training.
- Treadmill with optic flow with conventional physical therapy may be beneficial for improving gait speed, gait endurance, and functional mobility, but not balance, after stroke when compared to Treadmill with conventional physical therapy.
- Virtual Reality with Treadmill Training may be beneficial for improving gait speed, but not motor recovery, biomechanical gait measures, biomechanical balance measures, activities of daily living, gait endurance, and functional mobility, after stroke when compared to Overground Gait Training.
- Virtual Reality Robotic Training may be beneficial for improving neurophysiological measures, but not biomechanical gait measures, muscle strength, spasticity, activities of daily living, gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, after stroke when compared to Robotic Training and Conventional Therapy.
- Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may be beneficial for improving muscle strength, but not activities of daily living, functional mobility, and balance, after stroke when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy; the literature is mixed regarding gait speed.
- Virtual Reality Robotic Training may be beneficial for improving gait speed, but not activities of daily living, after stroke when compared to Robotic Training, Auditory Stimulation, and Conventional Therapy.

- Virtual Reality with Other Modalities may be beneficial for improving biomechanical gait measures, spasticity, and gait speed, but not aerobic measures, activities of daily living, and falls and fear of falling, after stroke when compared to Task-specific training; the literature is mixed regarding biomechanical balance measures, gait endurance, functional mobility, and balance.
- Task-oriented training with Virtual reality training may be beneficial for improving motor recovery and balance after stroke when compared to Task-oriented training; the literature is mixed regarding functional mobility.
- Virtual reality therapy and mirror therapy (MT) exercises may be beneficial for improving motor recovery and range of motion, but not spasticity and activities of daily living, after stroke when compared to lower extremity rehabilitation; the literature is mixed regarding balance.
- One session daily high intensity Videogame exercises with medical massage may result in lesser improvements in aerobic measures when compared to two sessions daily high intensity Videogame exercises with medical massage; the literature is mixed regarding biomechanical balance measures.
- Virtual Reality may not be beneficial for improving motor recovery, sensory and proprioceptive function, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Virtual Reality (Nintendo Wii) may not be beneficial for improving motor recovery after stroke when compared to Virtual Reality with Proprioceptive Neuromuscular Facilitation.
- Treadmill training with Virtual reality and Ankle robotics may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, range of motion, and gait speed after stroke when compared to Seated training with Virtual reality and Ankle robotics.
- Brain-Computer Interface Controlled Training may be beneficial for improving motor recovery, but not neurophysiological measures, activities of daily living, functional mobility, and balance, after stroke when compared to Sham.
- Virtual Reality Training may be beneficial for improving activities of daily living and functional mobility after stroke when compared to Strength and Resistance Training; the literature is mixed regarding balance.
- Adaptive foot switch Videogame with Regular physiotherapy may be beneficial for improving biomechanical balance measures after stroke when compared to Regular physiotherapy.
- Wii Balance Intervention may not be beneficial for improving functional mobility, balance, and falls and fear of falling after stroke when compared to Conventional Balance Intervention.
- Group Video game therapy may not be beneficial for improving gait speed after stroke when compared to Conventional care.
- Peripheral nerve mobilization with virtual reality-based gait training may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Conventional exercises.
- Motor imagery with virtual reality training may be beneficial for improving motor recovery, gait speed, functional mobility, and balance after stroke when compared to virtual reality training with Conventional therapy.
- Repetitive transcranial magnetic stimulation with Augmented reality gait adaptive training may be beneficial for improving motor recovery, gait speed, and balance, but not biomechanical gait measures, muscle strength, and neurophysiological measures, after stroke when compared to Augmented reality gait adaptive training.
- Selfpaced treadmill walking in virtual reality environment may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Self Placed Overground Platform walking.
- Lokomat endurance video games may not be beneficial for improving biomechanical gait measures after stroke when compared to Conventional Physiotherapy; the literature is mixed regarding gait speed, gait endurance, biomechanical balance measures, and balance.
- Xbox training during anodal tDCS stimulation to cerebellum may be beneficial for improving gait speed, functional mobility, and balance, but not gait endurance and falls and fear of falling, after stroke when compared to Sham tDCS with xbox training.
- Xbox training during anodal tDCS stimulation to cerebellum may not be beneficial for improving gait speed, gait endurance, functional mobility, and falls and fear of falling after stroke when compared to Xbox training during nodal tDCS stimulation to motor cortex; Xbox training during anodal tDCS stimulation to cerebellum may result in lesser improvements in balance when compared to Xbox training during nodal tDCS stimulation to motor cortex.

- Self paced treadmill walking in virtual reality environment may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Fixed speed treadmill walking in virtual reality environment.
- Telerehabilitation video games may not be beneficial for improving range of motion, pain, activities of daily living, balance, and quality of life after stroke when compared to Conventional rehab.
- Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy may be beneficial for improving muscle strength, gait speed, functional mobility, balance, and quality of life after stroke when compared to Sit-to-stand Training with physiotherapy.
- Treadmill-based with augmented reality may not be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Overground walking with physical obstacles.
- Telerehabilitation using a Kinect camera-based interactive telerehabilitation system may not be beneficial for improving muscle strength, functional mobility, balance, and falls and fear of falling after stroke when compared to Conventional physiotherapy.
- Virtual reality augmented robot-assisted gait training with conventional care may not be beneficial for improving activities of daily living, gait speed, functional mobility, balance, and falls and fear of falling after stroke when compared to Robot-assisted gait training with conventional care.
- Speed-Interactive Pedaling Training with Virtual Reality may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and balance after stroke when compared to Pedaling Training.
- Virtual Reality or Virtual Reality with Proprioceptive Neuromuscular Facilitation may not be beneficial for improving motor recovery, sensory and proprioceptive function, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Virtual Reality may not be beneficial for improving motor recovery after stroke when compared to Virtual Reality with Proprioceptive Neuromuscular Facilitation.
- Cognitive motor exergaming training may be beneficial for improving biomechanical balance measures, but not gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Conventional training (stretching, strengthening, balance and endurance training).
- Dual-task (virtual reality-based UL training while walking on treadmill) may be beneficial for improving gait speed, balance, and falls and fear of falling, but not functional mobility, after stroke when compared to Single task treadmill walking.
- Robotic-assisted gait training (Lokomat-Pro) with VR may be beneficial for improving neurophysiological measures and functional mobility, but not spasticity, after stroke when compared to Robotic-assisted gait training (Lokomat-Nanos).
- The literature is mixed regarding the effect of Virtual reality with cognitive load with conventional rehabilitation on biomechanical gait measures and gait speed after stroke when compared to Treadmill walking with virtual environment with conventional rehabilitation.
- Virtual walking training (virtual reality) with rehabilitation program may be beneficial for improving gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Treadmill gait training with rehabilitation.
- One session daily high intensity Videogame exercises with medical massage may be beneficial for improving activities of daily living after stroke when compared to Standard physical therapy with medical massage.
- Two sessions daily high intensity Videogame exercises with medical massage may not be beneficial for improving activities of daily living after stroke when compared to Standard physical therapy with medical massage.
- Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- Auditory stimulation with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.

- Virtual Reality with Proprioceptive Neuromuscular Facilitation may not be beneficial for improving motor recovery, sensory and proprioceptive function, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Anodal Cerebellar tDCS with Xbox Kinect games may be beneficial for improving falls and fear of falling, but not sensory and proprioceptive function, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Anodal M1 tDCS with Xbox Kinect games.
- Anodal Cerebellar tDCS with Xbox Kinect games may be beneficial for improving sensory and proprioceptive function, functional mobility, balance, and falls and fear of falling, but not gait speed and gait endurance, after stroke when compared to Sham Stimulation Group with Xbox Kinect games.
- Anodal M1 tDCS with Xbox Kinect games may be beneficial for improving sensory and proprioceptive function, functional mobility, and balance, but not gait speed, gait endurance, and falls and fear of falling, after stroke when compared to Sham Stimulation Group with Xbox Kinect games.
- Xbox training during nodal tDCS stimulation to motor cortex may be beneficial for improving balance, but not gait speed, gait endurance, functional mobility, and falls and fear of falling, after stroke when compared to Sham tDCS with xbox training.

Summary of Key Points: Virtual Reality

Intervention	Control(s)	Function domain(s)	Effect
Virtual Reality	Conventional Therapy or No Treatment	Sensory and proprioceptive function, gait speed, functional mobility	+
Virtual Reality	Conventional Therapy or No Treatment	Motor recovery, biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, neurophysiological measures, pain, activities of daily living, gait endurance, balance, falls and fear of falling, quality of life	–
Virtual Reality	Conventional Therapy or No Treatment	Range of motion	=
Game-based constraint-induced movement therapy with Traditional physical therapy	General game-based training with Traditional physical therapy	Biomechanical gait measures, biomechanical balance measures	+
Game-based constraint-induced movement therapy with Traditional physical therapy	General game-based training with Traditional physical therapy	Gait speed, functional mobility, balance	–
Virtual Reality	Balance Training	Activities of daily living, functional mobility	+
Virtual Reality	Balance Training	Gait speed, balance, falls and fear of falling	–
Virtual Reality Exercise Program	Exercise Program	Falls and fear of falling	+
Virtual Reality Exercise Program	Exercise Program	Motor recovery, biomechanical gait measures, functional mobility, balance, quality of life	–
Virtual Reality Exercise Program	Exercise Program	Gait speed	=
Virtual Reality Training	Treadmill Training	Biomechanical gait measures	–
Virtual Reality Training	Treadmill Training	Biomechanical balance measures	=
Virtual Reality with Treadmill Training	Conventional Therapy or Treadmill Training	Gait speed, balance, falls and fear of falling	+

Virtual Reality with Treadmill Training	Conventional Therapy or Treadmill Training	Biomechanical gait measures, biomechanical balance measures, gait endurance, functional mobility, quality of life	–
Virtual reality treadmill training-based community ambulation	Community ambulation training	Biomechanical gait measures, gait speed, gait endurance, functional mobility, falls and fear of falling	–
Treadmill with optic flow with conventional physical therapy	Treadmill with conventional physical therapy	Gait speed, gait endurance, functional mobility	+
Treadmill with optic flow with conventional physical therapy	Treadmill with conventional physical therapy	Balance	–
Virtual Reality with Treadmill Training	Overground Gait Training	Gait speed	+
Virtual Reality with Treadmill Training	Overground Gait Training	Motor recovery, biomechanical gait measures, biomechanical balance measures, activities of daily living, gait endurance, functional mobility	–
Virtual Reality Robotic Training	Robotic Training and Conventional Therapy	Neurophysiological measures	+
Virtual Reality Robotic Training	Robotic Training and Conventional Therapy	Biomechanical gait measures, muscle strength, spasticity, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling	–
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy	Muscle strength	+
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy	Activities of daily living, functional mobility, balance	–
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy	Gait speed	=
Virtual Reality Robotic Training	Robotic Training, Auditory Stimulation, and Conventional Therapy	Gait speed	+
Virtual Reality Robotic Training	Robotic Training, Auditory Stimulation, and Conventional Therapy	Activities of daily living	–
Virtual Reality with Other Modalities	Task-specific training	Biomechanical gait measures, spasticity, gait speed	+
Task-oriented training with Virtual reality training	Task-oriented training	Motor recovery, balance	+
Task-oriented training with Virtual reality training	Task-oriented training	Functional mobility	=
Virtual reality therapy and mirror therapy (MT) exercises	lower extremity rehabilitation	Motor recovery, range of motion	+
Virtual reality therapy and mirror therapy (MT) exercises	lower extremity rehabilitation	Spasticity, activities of daily living	–
Virtual reality therapy and mirror therapy (MT) exercises	lower extremity rehabilitation	Balance	=

One session daily high intensity Videogame exercises with medical massage	two sessions daily high intensity Videogame exercises with medical massage	Aerobic measures	−
One session daily high intensity Videogame exercises with medical massage	two sessions daily high intensity Videogame exercises with medical massage	Biomechanical balance measures	=
Virtual Reality with Other Modalities	Task-specific training	Aerobic measures, activities of daily living, falls and fear of falling	−
Virtual Reality	Proprioceptive Neuromuscular Facilitation	Motor recovery, sensory and proprioceptive function, balance	−
Virtual Reality (Nintendo Wii)	Virtual Reality with Proprioceptive Neuromuscular Facilitation	Motor recovery	−

Anodal Cerebellar tDCS with Xbox Kinect games	Anodal M1 tDCS with Xbox Kinect games	Sensory and proprioceptive function, gait speed, gait endurance, functional mobility, balance	–
Anodal Cerebellar tDCS with Xbox Kinect games	Sham Stimulation Group with Xbox Kinect games	Sensory and proprioceptive function, functional mobility, balance, falls and fear of falling	+
Anodal Cerebellar tDCS with Xbox Kinect games	Sham Stimulation Group with Xbox Kinect games	Gait speed, gait endurance	–
Anodal M1 tDCS with Xbox Kinect games	Sham Stimulation Group with Xbox Kinect games	Sensory and proprioceptive function, functional mobility, balance	+
Anodal M1 tDCS with Xbox Kinect games	Sham Stimulation Group with Xbox Kinect games	Gait speed, gait endurance, falls and fear of falling	–

Electromechanical and Robotic Devices

Adopted from: http://internationalmedipol.com/lokomat-robotic-walking-system; https://www.odtmag.com/contents/view_breaking-news/2018-03-02/hybrid-assistive-limb-hal-treatment-for-spinal-cord-injury-available-in-us

Recently, considerable effort has been invested in developing electromechanical-assisted training devices for gait training. Most of these devices are generally classified as either an “end-effector device” (i.e. patients are placed on foot plates that stimulate the stance and swing phases of gait) or an “exoskeleton device” (i.e. patients are outfitted with a programmable device that moves the hips and knees during gait). The most commonly studied end-effector device is the Gait Trainer (Reha-Stim; Berlin Germany), while the Lokomat (Hokoma; Zurich, Switzerland) is the most studied exoskeleton device (Mehrholz & Pohl, 2012). Other exoskeleton devices that have been studied can be classified as either an exoskeleton system or an exoskeleton portable device. A third category of electromechanical devices can be described as a robotic arm control system group, as described by Ochi et al. 2015.

The main advantage electromechanical devices may offer over conventional gait training is that they may increase the number of repetitions performed and reduce the need for intensive therapist involvement, thereby increasing therapist productivity and accelerating patient recovery. A table of various robotic devices used in stroke rehabilitation is outlined below (Table 28). Table 28. Electromechanical devices used for lower limb rehabilitation post-stroke Electromechanical Devices Description End-Effectors The G-EO system is a gait-trainer robotic • G-EO System device that provides a supportive harness • Gait Trainer I and II (GT I, GT II) and uses foot plates to simulate floor walking and also walking up and down stairs.

The GT II is a gait-trainer robotic device that offers body weight support through a harness and also endpoint feet trajectories through foot plates (Iosa et al., 2011).

Exoskeleton Systems The Lokomat is a widely used exoskeleton • Lokomat device that features a treadmill, a dynamic • Walkbot body weight support system, and a motor- • Hybrid Assistive Limb (HAL) driven robotic orthosis (Bae et al. 2016). The • AutoAmbulator robotic orthosis is used to control gait pattern through adjusting gait speed, guidance force, • LokoHelp and support from body weight (Bae et al. 2016).

The Walkbot is a gait rehabilitation exoskeleton that features powered hip-knee- ankle joint drive motor design as well as a biofeedback platform (Kim et al. 2015h).

The HAL is a wearable robotic exoskeleton that supports participants in walking, standing, and performing other leg movements (Yoshikawa et al., 2018). The HAL detects bioelectrical signals generated by muscles and floor-reaction-force signals and responds to the user’s voluntary movements instead of following a predefined motion (Yoshikawa et al., 2018).

The AutoAmbulator is a gait rehabilitation exoskeleton that provides body weight support treadmill training with the assistance of a harness and robot arms. The robot arms have four degrees of freedom and control various aspects of the gait cycle (Fisher et al. 2011).

The LokoHelp device is placed on top of a treadmill and is an easily installed or removed. It works through transmitting the treadmill movement to levers on either side of the device which then create movements that imitate stance and swing phases of gait (Freivogel et al. 2009).

Exoskeleton Portable Devices The Stride Management Assist (SMA) device • Stride Management Assist (SMA) is a robotic exoskeleton that provides • Anklebot assistance with high flexion and extension in • Bionic Leg each leg. This device uses neural oscillators and the user’s Central Pattern Generator to generate assist torques during the gait cycle to regulate walking patterns (Buesing et al. 2015).

The Anklebot is a robotic device consisting of a knee brace that is attached to a custom shoe (Forrester et al., 2013). It is designed to strengthen the ankle and the lower extremity through adjusting the force applied depending on varying requirements (Forrester et al., 2013).

The Bionic Leg device is a powered knee orthosis that uses sensors, accelerometers, and joint angle detectors to detect the user’s movements and provide mechanical assistance (Stein et al. 2014).

Robotic Arm Control System The gait-assistance robot is a robotic arm • Gait-Assistance Robot (GAR) control system that includes 4 robotic arms, a full weight-bearing system, and a visual foot pressure biofeedback system (Nakanishi et al., 2014). The four separate robotic arms provide the ability to move the lower body automatically and independently (Ochi et al. 2015). This device does not suspend a patient with a harness and thus promotes full body weight bearing while on a treadmill (Ochi et al. 2015).

A total of 127 RCTs were found that evaluated electromechanical and robotic devices for lower extremity motor rehabilitation. 24 RCTs compared Robot Assisted Gait Training with Conventional Therapy and Overground Gait Training (Hirano et al. 2024; Huo et al. 2024; Lee et al. 2024a; Tang et al. 2024; Zhang et al. 2024d; Akinci et al. 2023; Lee et al. 2023a; Talaty et al. 2023; Yoo et al. 2023b; Zhang et al. 2023b; Thimabut et al. 2022; Lin et al.

2022a; Alingh et al. 2021; Kooncumchoo et al. 2021; Song et al. 2021b; Stolz et al. 2019; Kim et al. 2019a; Lee et al. 2019a; Morone et al. 2018; Bizovicar et al. 2017; Chua et al. 2016; Morone et al. 2016; Peurala et al. 2009; Ng et al. 2008). One RCT compared Early Robot Assisted Gait Training with Late Start Robot Assisted Gait Training (Kim et al. 2020c). One RCT compared Robot Assisted Gait Training with Balance Training (Gandolfi et al. 2019). Five RCTs compared Electromechanical Gait Training with Conventional Treatment or No Treatment (Liu et al. 2022; Tanaka et al. 2012; Pohl et al. 2007; Tong et al. 2006; Peurala et al. 2005). Two RCTs compared End-Effector Gait Training with Body Weight Supported Treadmill (Kim et al. 2020c; Werner et al. 2002b). 46 RCTs compared Exoskeleton Systems with Conventional Therapy or Overground Gait Training (Zhang et al. 2024b; Xie et al. 2023; Yokota et al. 2023; Miyagawa et al. 2023; Nam et al. 2022b; Kang et al. 2021b; Louie et al. 2021; Kotov et al. 2021; Li et al. 2021b; Li et al. 2021c; Molteni et al. 2021; Palmcrantz et al. 2021; Yu et al. 2021; Mustafaoglu et al. 2020; Nam et al. 2020; Park et al. 2020c; Rojek et al. 2020; Wall et al. 2020; Lee et al. 2019a; Nam et al. 2019; Sczesny-Kaiser et al. 2019; Wall et al. 2019; Kim et al. 2019a; Bergmann et al. 2018b; Mayr et al. 2018; Yun et al. 2018; Calabro et al. 2018; Han et al. 2016; Taveggia et al. 2016; Cho et al. 2015a; Kim et al. 2015h; Ochi et al. 2015; van Nunen 2015; Ucar et al. 2014; Watanabe et al. 2014; Wu et al. 2014; Kelley et al. 2013; Chang et al. 2012; Fisher et al. 2011; Morone et al. 2011; Freivogel et al. 2009; Hidler et al. 2009; Lewek et al. 2009; Schwartz et al. 2009; Hornby et al. 2008; Husemann et al. 2007). Five RCTs compared Exoskeleton Systems with Treadmill Training (Yoo et al. 2023a; Choi et al. 2022; Lee et al. 2022b; Bang & Shin 2016b; Westlake & Patten 2009). One RCT compared Exoskeleton Gait Training with Functional Task-Specific Training (Jayaraman et al. 2019). Two RCTs evaluated Exoskeleton Systems Administration Method (Jiae et al. 2022; Bae et al. 2016). Six RCTs compared Exoskeleton Portable Devices with Overground Gait Training or Stretching vs Sham Ankle Foot Orthosis (Wright et al. 2021; Yeung et al. 2021; Buesing et al. 2015; Goodman et al. 2014; Stein et al. 2014; Waldman et al. 2013). Two RCTs compared Exoskeleton Portable Devices with Stretching (Zhai et al. 2021; Forrester et al. 2014). One RCT compared Exoskeleton Portable Devices with Ankle Foot Orthosis with Sham Ankle Foot Orthosis (Yeung et al. 2018). Two RCTs evaluated Robotic-Assisted Gait Training and Restraint (Kang et al. 2018; Bonnyaud et al. 2014a). Three RCTs compared Robotics Combined with Virtual Reality with Robotics, Robotics Combined with Auditory Stimulation or Conventional Training (Kayabinar et al. 2021; Park et al. 2018a; Calabrò et al. 2017). One RCT compared Lokomat Training with Galvanic Vestibular Stimulation or Physiotherapy with Visual Feedback (Krewer et al. 2013). One RCT compared Robot as Gait Training as Needed with Robot Assisted Gait Training Full Time (Seo et al. 2018). One RCT compared Robot-assisted Trunk Training with Conventional Therapy (Kim et al. 2022f). One RCT compared Gait Training with Gait Exercise Assist Robot (GEAR) with Gait Training with Treadmill (Ogino et al. 2020). One RCT compared Gait Training with Gait Exercise Assist Robot (GEAR) with Overground Gait Training (Tomida et al. 2019). One RCT compared Robotic Verticalization + FES with Conventional therapy (Calabro et al. 2015). One RCT compared Robotic-assisted Stretching with Conventional Therapy (Yoo et al. 2018a). One RCT compared Regent Suit + Neuromotor rehabilitation with Neuromotor rehabilitation (Monticone et al. 2013). One RCT compared Vibration on sole of foot with Contact on Sole of Foot with No Vibration (Onal et al. 2020). One RCT evaluated Robot-Assisted Gait Training with Visuomotor Feedback (Maggio et al. 2021). Three RCTs compared Robotics with Treadmill Training and Virtual Reality with Seated Training (Tamburella et al. 2019; Forrester et al. 2016; Bustamante Valles et al. 2016). One RCT compared Robot-assisted Task Specific Training with Task Specific Walking (Buesing et al. 2015). One RCT evaluated Comparison of Robot-Assisted Gait Training Systems (Elmas Bodur et al. 2024). One RCT evaluated Comparison of Ankle Robot Training Intensity and Frequency (Zhang et al. 2023a). One RCT compared Robot-Guided Ankle Proprioceptive Training with Thermal Stimulation with Conventional Therapy (Mao et al. 2022b). One RCT compared Robot-Assisted Gait Training with Robotic Balance Platform with Robot-Assisted Gait Training Alone (Aprile et al. 2022). One RCT compared Robot-Assisted Gait Training with Upper Limb Therapy (Lin et al. 2022b). One RCT compared Robot-Assisted Gait Training with Balance Training with Balance Training Alone (Gunduz et al. 2024). One RCT compared Robot-Assisted Gait Training with Home-Based Exercise Program (Do et al. 2024).

In addition, 30 RCTs in which electromechanical and robotic devices formed part of a combined or comparative intervention are cross-referenced at the end of Table 27; their primary listings appear in other tables.

The methodological details and results of all 127 RCTs are presented in Table 27.

Table 27. RCTs Evaluating Electromechanical and Robotic Devices for Lower Extremity Motor Rehabilitation

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1a	Robot Assisted Gait Training may not have a difference in efficacy when compared to Conventional Therapy and Overground Gait Training for improving motor recovery.	14	Hirano et al. 2024; Huo et al. 2024; Lee et al. 2024a; Tang et al. 2024; Zhang et al. 2024d; Lee et al. 2023a; Yoo et al. 2023b; Zhang et al. 2023b; Lin et al. 2022a; Alingh et al. 2021; Kooncumchoo et al. 2021; Lee et al. 2019a; Morone et al. 2016; Peurala et al. 2009
2	Gait Trainer GT I (Rehastim) may not have a difference in efficacy when compared to Overground gait training for improving motor recovery.	1	Peurala et al. 2009
1b	End-Effector Gait Training may produce greater improvements in motor recovery than Body Weight Supported Treadmill.	1	Kim et al. 2020c
1b	Electromechanical gait trainer therapy with Conventional rehabilitation may not have a difference in efficacy when compared to Body weight-supported treadmill training with Conventional rehabilitation for improving motor recovery.	1	Werner et al. 2002b
1a	Exoskeleton Systems may not have a difference in efficacy when compared to Conventional Therapy or Overground Gait Training for improving motor recovery.	24	Zhang et al. 2024b; Xie et al. 2023; Yokota et al. 2023; Louie et al. 2021; Li et al. 2021b; Li et al. 2021c; Palmcrantz et al. 2021; Yu et al. 2021; Mustafaoglu et al. 2020; Wall et al. 2020; Lee et al. 2019a; Kim et al. 2019a; Mayr et al. 2018; Yun et al. 2018; Han et al. 2016; Cho et al. 2015a; Ochi et al. 2015; van Nunen 2015; Watanabe et al. 2014; Kelley et al. 2013; Chang et al. 2012; Morone et al. 2011; Hidler et al. 2009; Schwartz et al. 2009
1b	Robot-assisted gait training with Conventional care may not have a difference in efficacy when compared to Conventional gait training with Conventional care for improving motor recovery in patients with high motricity.	1	Morone et al. 2011
1b	Robot Assisted Gait Training (Lokomat) with Conventional Therapy may not have a difference in efficacy when compared to Robot Assisted Gait Training (Lokomat) for improving motor recovery.	1	Mustafaoglu et al. 2020
1b	Exoskeleton Systems may not have a difference in efficacy when compared to Treadmill Training for improving motor recovery.	1	Westlake & Patten 2009
2	Exoskeleton Gait Training may not have a difference in efficacy when compared to Functional Task-Specific Training for improving motor recovery.	1	Jayaraman et al. 2019
1b	Exoskeleton Systems Administration Method may produce greater improvements in motor recovery than Therapist controlled robot-assisted gait training.	1	Bae et al. 2016
2	Exoskeleton Portable Devices may not have a difference in efficacy when compared to Overground Gait Training or Stretching or Sham Ankle Foot Orthosis for improving motor recovery.	1	Goodman et al. 2014
1b	Exoskeleton Portable Devices may not have a difference in efficacy when compared to Stretching for improving motor recovery.	1	Zhai et al. 2021

2	Exoskeleton Portable Devices with Ankle Foot Orthosis may produce greater improvements in motor recovery than Sham Ankle Foot Orthosis.	1	Yeung et al. 2018
1b	Robotic-Assisted Gait Training and Restraint may produce greater improvements in motor recovery than Robot-assisted (Lokomat) walking training with arm fixation with conventional care.	1	Kang et al. 2018
1b	Robotics Combined with Virtual Reality may produce greater improvements in motor recovery than Robotics, Robotics Combined with Auditory Stimulation or Conventional Training.	1	Park et al. 2018a
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may produce greater improvements in motor recovery than Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.	1	Park et al. 2018a
2	Assist-as-needed robot- assisted gait training for unaffected limb with fully-assisted robot-assisted training for affected limb may not have a difference in efficacy when compared to Assist-as-needed robot- assisted gait training for affected limb with fully-assisted robot-assisted training for unaffected limb for improving motor recovery.	1	Seo et al. 2018
2	Gait Training with Gait Exercise Assist Robot (GEAR) may not have a difference in efficacy when compared to Overground Gait Training for improving motor recovery.	1	Tomida et al. 2019
2	Robotic Verticalization with functional electrical stimulation may produce greater improvements in motor recovery than Conventional therapy.	1	Calabro et al. 2015
1b	There is conflicting evidence about the effect of Robot-Assisted Gait Training with Visuomotor feedback when compared to Robot-Assisted Gait Training for improving motor recovery.	1	Maggio et al. 2021
2	Robotics with Treadmill Training and Virtual Reality may produce greater improvements in motor recovery than Seated Training.	1	Bustamante Valles et al. 2016
1b	Ankle robot training low frequency, low intensity may not have a difference in efficacy when compared to ankle robot training high frequency, low intensity or ankle robot training low frequency, high intensity or ankle robot training high frequency, high intensity for improving motor recovery.	1	Zhang et al. 2023a
1b	Robot-Guided Ankle Proprioceptive Training with Thermal Stimulation may produce greater improvements in motor recovery than Conventional Therapy.	1	Mao et al. 2022b
1b	Robot-Assisted Gait Training may produce greater improvements in motor recovery than Upper Limb Therapy.	1	Lin et al. 2022b
1b	There is conflicting evidence about the effect of Robot-Assisted Gait Training with Balance Training when compared to Balance Training Alone for improving motor recovery.	1	Gunduz et al. 2024
1b	Robot-Assisted Gait Training may produce greater improvements in motor recovery than Home-Based Exercise Program.	1	Do et al. 2024
2	Ankle-knee-hip Interlimb coordinated humanoid robot + Conventional Physical therapy may not have a difference in efficacy when compared to Gait training + Conventional PT for improving motor recovery.	1	Park et al. 2021c
2	Gait trainer device (REHA-STIM) may not have a difference in efficacy when compared to Conventional rehabilitation (Bobath) for improving motor recovery.	1	Dias et al. 2007
2	2x Lokomat gait training + 1x Conventional PT may not have a difference in efficacy when compared to 2x Conventional PT + 1x Lokomat gait training for improving motor recovery.	1	Mayr et al. 2007

1b	Daoyin with Conventional rehab may produce greater improvements in motor recovery than Conventional rehab.	1	Haolin et al. 2024
1b	Daoyin with Conventional rehab may not have a difference in efficacy when compared to Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab for improving motor recovery.	1	Haolin et al. 2024
1b	Lower Limb Robot with Conventional rehab may not have a difference in efficacy when compared to Daoyin with Lower Limb Robot with Conventional rehab for improving motor recovery.	1	Haolin et al. 2024
1b	There is conflicting evidence about the effect of High definition transcranial direct current stimulation (dual) with Robot assisted gait training when compared to Sham High definition transcranial direct current stimulation with Robot assisted gait training for improving motor recovery.	1	Kim et al. 2024b
1b	Robotic balance training with conventional rehabilitation may not have a difference in efficacy when compared to Conventional training for improving motor recovery.	1	Inoue et al. 2022b
2	Brain-computer interface- controlled training robot with Conventional Physiotherapy may not have a difference in efficacy when compared to Sham brain-computer interface-controlled training robot with Conventional Physiotherapy for improving motor recovery.	1	Zhao et al. 2022c
1b	Dynamic tilt table with robotic leg movement with functional electrical stimulation may not have a difference in efficacy when compared to dynamic tilt table with robotic leg movement for improving motor recovery.	1	Ueda et al. 2022
1b	Interactive Dynamic Scalp Acupuncture with lower-limb robot training (SA & LLRT simultaneously) and Basic Treatment may produce greater improvements in motor recovery than Scalp Acupuncture with Basic Treatment.	1	Zhang et al. 2021c
1b	Trunk stability robot training (3DBT-33) with conventional physical therapy may produce greater improvements in motor recovery than Conventional Physical Therapy.	1	Min et al. 2020
2	There is conflicting evidence about the effect of Haemorrhagic Stroke Erigo Robotic Tilt Table when compared to Haemorrhagic Stroke Conventional Care or Ischemic Stroke Conventional Care for improving motor recovery.	1	Yadav et al. 2020
1b	Robot-assisted gait training and anodal transcranial direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training and sham stimulation for improving motor recovery.	1	Seo et al. 2017
2	Overground gait training using E-Go device with Standard Physiotherapy may not have a difference in efficacy when compared to Overground walking training with Standard Physiotherapy for improving motor recovery.	1	Bizovicar et al. 2017
1b	Brain-computer interface- operated lower limb rehabilitation robot may produce greater improvements in motor recovery than Sham (Lower limb pedal training without image, video, sound hint).	1	Li et al. 2021a

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Robot Assisted Gait Training may not have a difference in efficacy when compared to Conventional Therapy and Overground Gait Training for improving biomechanical gait measures.	7	Zhang et al. 2024d; Akinci et al. 2023; Zhang et al. 2023b; Thimabut et al. 2022; Alingh et al. 2021; Stolz et al. 2019; Lee et al. 2019a

2	Ankle-knee-hip Interlimb coordinated humanoid robot + Conventional Physical therapy may not have a difference in efficacy when compared to Gait training + Conventional PT for improving biomechanical gait measures.	1	Park et al. 2021c
1b	Healbot T (Exoskeleton) with pelvic motion on may not have a difference in efficacy when compared to Healbot T (Exoskeleton) with pelvic motion off for improving biomechanical gait measures.	1	Son et al. 2021
2	Gait trainer device (REHA-STIM) may not have a difference in efficacy when compared to Conventional rehabilitation (Bobath) for improving biomechanical gait measures.	1	Dias et al. 2007
2	Acupuncture with Gait rehab robot training (AiWalker-I) and Conventional rehab may produce greater improvements in biomechanical gait measures than Acupuncture with Conventional rehab.	1	Hu et al. 2024
1b	Dynamic tilt table with robotic leg movement with functional electrical stimulation may not have a difference in efficacy when compared to dynamic tilt table with robotic leg movement for improving biomechanical gait measures.	1	Ueda et al. 2022
1b	Interactive Dynamic Scalp Acupuncture with lower-limb robot training (SA & LLRT simultaneously) and Basic Treatment may produce greater improvements in biomechanical gait measures than Scalp Acupuncture with Basic Treatment.	1	Zhang et al. 2021c
1b	Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training may not have a difference in efficacy when compared to Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training for improving biomechanical gait measures.	1	Picelli et al. 2019
2	Robotic ankle stretching exercises may not have a difference in efficacy when compared to Conventional stretching board for improving biomechanical gait measures.	1	Yoo et al. 2018a
1b	Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may result in lesser improvements in biomechanical gait measures when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA).	1	Picelli et al. 2015
1b	Robot-assisted (Lokomat) gait training with functional electrical stimulation on the ankle dorsiflexor of affected side may not have a difference in efficacy when compared to Robot-assisted (Lokomat) gait training for improving biomechanical gait measures.	1	Bae et al. 2014
1b	Anodal transcranial direct current stimulation with Robot- assisted gait training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Robot- assisted gait training for improving biomechanical gait measures.	1	Geroin et al. 2011
1b	Anodal transcranial direct current stimulation with Robot- assisted gait training may produce greater improvements in biomechanical gait measures than Gait training.	1	Geroin et al. 2011

2	Virtual reality robotic training (computer) may not have a difference in efficacy when compared to Robotic training for improving biomechanical gait measures.	1	Mirelman et al. 2009

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Robot Assisted Gait Training may not have a difference in efficacy when compared to Conventional Therapy and Overground Gait Training for improving biomechanical balance measures.	1	Akinci et al. 2023
1b	Robot Assisted Gait Training may not have a difference in efficacy when compared to Balance Training for improving biomechanical balance measures.	1	Gandolfi et al. 2019
1b	Electromechanical Gait Training may not have a difference in efficacy when compared to Conventional Treatment or No Treatment for improving biomechanical balance measures.	1	Peurala et al. 2005
1b	Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy may not have a difference in efficacy when compared to Electromechanical gait trainer with Conventional therapy for improving biomechanical balance measures.	1	Peurala et al. 2005
1b	There is conflicting evidence about the effect of Exoskeleton Systems when compared to Conventional Therapy or Overground Gait Training for improving biomechanical balance measures.	2	Rojek et al. 2020; Kim et al. 2019a
1b	Robot-assisted Trunk Training may produce greater improvements in biomechanical balance measures than Conventional Therapy.	1	Kim et al. 2022f
2	Robotic-assisted Stretching may produce greater improvements in biomechanical balance measures than Conventional Therapy.	1	Yoo et al. 2018a
1b	Vibration on sole of foot may produce greater improvements in biomechanical balance measures than Contact on Sole of Foot with No Vibration.	1	Onal et al. 2020
2	Robotics with Treadmill Training and Virtual Reality may not have a difference in efficacy when compared to Seated Training for improving biomechanical balance measures.	1	Forrester et al. 2016
2	Robot-Assisted Gait Training with Robotic Balance Platform may not have a difference in efficacy when compared to Robot-Assisted Gait Training Alone for improving biomechanical balance measures.	1	Aprile et al. 2022
1b	Robotic balance training with conventional rehabilitation may not have a difference in efficacy when compared to Conventional training for improving biomechanical balance measures.	1	Inoue et al. 2022b
2	Robotic ankle stretching exercises may produce greater improvements in biomechanical balance measures than Conventional stretching board.	1	Yoo et al. 2018a

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Robot Assisted Gait Training may produce greater improvements in muscle strength than Conventional Therapy and Overground Gait Training.	5	Alingh et al. 2021; Song et al. 2021b; Kim et al. 2019b; Lee et al. 2019a; Ng et al. 2008
1b	Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous	1	Picelli et al. 2015

	spinal direct current stimulation (2.5mA) for improving muscle strength.		
1b	Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation may not have a difference in efficacy when compared to Gait Trainer GT II (Rehastim) with Regular rehabilitation for improving muscle strength.	1	Ng et al. 2008
1a	There is conflicting evidence about the effect of Electromechanical Gait Training when compared to Conventional Treatment or No Treatment for improving muscle strength.	2	Pohl et al. 2007; Peurala et al. 2005
1b	Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy may not have a difference in efficacy when compared to Electromechanical gait trainer with Conventional physical therapy for improving muscle strength.	1	Tong et al. 2006
1b	Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy may not have a difference in efficacy when compared to Electromechanical gait trainer with Conventional therapy for improving muscle strength.	1	Peurala et al. 2005
1a	Exoskeleton Systems may not have a difference in efficacy when compared to Conventional Therapy or Overground Gait Training for improving muscle strength.	14	Nam et al. 2022b; Kang et al. 2021b; Molteni et al. 2021; Nam et al. 2020; Lee et al. 2019a; Nam et al. 2019; Cho et al. 2015a; Ochi et al. 2015; van Nunen 2015; Watanabe et al. 2014; Chang et al. 2012; Morone et al. 2011; Freivogel et al. 2009; Husemann et al. 2007
1b	Robot-assisted gait training with Conventional care may not have a difference in efficacy when compared to Conventional gait training with Conventional care for improving muscle strength in patients with high or low motricity.	1	Morone et al. 2011
2	ExoAtlet exoskeleton exercises with rehabilitation may produce greater improvements in muscle strength than Ortorent MOTO pedal trainer for active-passive training with rehabilitation.	1	Kotov et al. 2021
2	Exoskeleton Portable Devices may produce greater improvements in muscle strength than Overground Gait Training or Stretching or Sham Ankle Foot Orthosis.	1	Waldman et al. 2013
1b	Exoskeleton Portable Devices may not have a difference in efficacy when compared to Stretching for improving muscle strength.	2	Zhai et al. 2021; Forrester et al. 2014
1b	Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may produce greater improvements in muscle strength than Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.	1	Park et al. 2018a
1b	Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy or Auditory stimulation with robot-assisted gait training (Treadmill) with conventional physical therapy may produce greater improvements in muscle strength than Conventional physical therapy with treadmill training.	1	Park et al. 2018a
2	Assist-as-needed robot- assisted gait training for unaffected limb with fully-assisted robot-assisted training for affected limb may not have a difference in efficacy when compared to Assist-as-needed robot- assisted gait training for affected limb with fully-assisted robot-assisted training for unaffected limb for improving muscle strength.	1	Seo et al. 2018
2	Robotic Verticalization with functional electrical stimulation may produce greater improvements in muscle strength than Conventional therapy.	1	Calabro et al. 2015

2	Robot-Assisted Gait Training with Robotic Balance Platform may not have a difference in efficacy when compared to Robot-Assisted Gait Training Alone for improving muscle strength.	1	Aprile et al. 2022
1b	Robot-Assisted Gait Training may not have a difference in efficacy when compared to Home-Based Exercise Program for improving muscle strength.	1	Do et al. 2024
1b	Progressive reducing assistance force during robot-assisted gait training + conventional PT may produce greater improvements in muscle strength than Full assistance force during robot-assisted gait training + conventional PT.	1	Park et al. 2019d
2	Gait trainer device (REHA-STIM) may not have a difference in efficacy when compared to Conventional rehabilitation (Bobath) for improving muscle strength.	1	Dias et al. 2007
2	2x Lokomat gait training + 1x Conventional PT may not have a difference in efficacy when compared to 2x Conventional PT + 1x Lokomat gait training for improving muscle strength.	1	Mayr et al. 2007
1b	Robotic balance training with conventional rehabilitation may not have a difference in efficacy when compared to Conventional training for improving muscle strength.	1	Inoue et al. 2022b
2	Robotic tilt table (Erigo) therapy may produce greater improvements in muscle strength than Conventional physiotherapy.	1	Kumar et al. 2020
2	There is conflicting evidence about the effect of Haemorrhagic Stroke Erigo Robotic Tilt Table when compared to Haemorrhagic Stroke Conventional Care or Ischemic Stroke Conventional Care for improving muscle strength.	1	Yadav et al. 2020
1b	Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training may not have a difference in efficacy when compared to Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training for improving muscle strength.	1	Picelli et al. 2019
2	Robotic Tilt table with Upper extremity exercises may produce greater improvements in muscle strength than Conventional therapy.	1	Yadav et al. 2018
2	Robot-assisted gait training with Virtual reality may not have a difference in efficacy when compared to Robot-assisted gait training for improving muscle strength.	1	Bergmann et al. 2018b
1b	Robot-assisted gait training and anodal transcranial direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training and sham stimulation for improving muscle strength.	1	Seo et al. 2017
1b	Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA) for improving muscle strength.	1	Picelli et al. 2015

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Robot Assisted Gait Training may not have a difference in efficacy when compared to Conventional Therapy and Overground Gait Training for improving spasticity.	1	Morone et al. 2016
1b	Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2.5mA) for improving spasticity.	1	Picelli et al. 2015
1b	Electromechanical gait trainer therapy with Conventional rehabilitation may not have a difference in efficacy when compared to Body weight-supported treadmill training with Conventional rehabilitation for improving spasticity.	1	Werner et al. 2002b
1a	Exoskeleton Systems may not have a difference in efficacy when compared to Conventional Therapy or Overground Gait Training for improving spasticity.	8	Kang et al. 2021b; Li et al. 2021c; Molteni et al. 2021; Cho et al. 2015a; Kim et al. 2015h; Morone et al. 2011; Freivogel et al. 2009; Husemann et al. 2007
1b	Robot-assisted gait training with Conventional care may not have a difference in efficacy when compared to Conventional gait training with Conventional care for improving spasticity in patients with high or low motricity.	1	Morone et al. 2011
2	ExoAtlet exoskeleton exercises with rehabilitation may not have a difference in efficacy when compared to Ortorent MOTO pedal trainer for active-passive training with rehabilitation for improving spasticity.	1	Kotov et al. 2021
2	Exoskeleton Portable Devices may produce greater improvements in spasticity than Overground Gait Training or Stretching or Sham Ankle Foot Orthosis.	1	Waldman et al. 2013
1b	Exoskeleton Portable Devices may not have a difference in efficacy when compared to Stretching for improving spasticity.	1	Zhai et al. 2021
2	Exoskeleton Portable Devices with Ankle Foot Orthosis may not have a difference in efficacy when compared to Sham Ankle Foot Orthosis for improving spasticity.	1	Yeung et al. 2018
1b	Robotics Combined with Virtual Reality may not have a difference in efficacy when compared to Robotics, Robotics Combined with Auditory Stimulation or Conventional Training for improving spasticity.	1	Calabro et al. 2017
2	Robotics with Treadmill Training and Virtual Reality may not have a difference in efficacy when compared to Seated Training for improving spasticity.	1	Tamburella et al. 2019
2	Ankle-knee-hip Interlimb coordinated humanoid robot + Conventional Physical therapy may not have a difference in efficacy when compared to Gait training + Conventional PT for improving spasticity.	1	Park et al. 2021c
2	2x Lokomat gait training + 1x Conventional PT may not have a difference in efficacy when compared to 2x Conventional PT + 1x Lokomat gait training for improving spasticity.	1	Mayr et al. 2007
1b	Robotic Gait Training (Lokomat robotic exoskeleton) with Botulinum toxin injection may not have a difference in efficacy when compared to Botulinum toxin injection with Conventional physiotherapy for improving spasticity.	1	Cotinat et al. 2024

2	There is conflicting evidence about the effect of Haemorrhagic Stroke Erigo Robotic Tilt Table when compared to Haemorrhagic Stroke Conventional Care or Ischemic Stroke Conventional Care for improving spasticity.	1	Yadav et al. 2020
1b	Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training may not have a difference in efficacy when compared to Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training for improving spasticity.	1	Picelli et al. 2019
2	Botulinum toxin A with Robot assisted Gait Training (RoboGait) and Conventional Physiotherapy may not have a difference in efficacy when compared to Botulinum toxin A with Conventional Physiotherapy or 90min physical therapy 1session/d, 5d/wk, for 3wks for improving spasticity.	1	Erbil et al. 2018
1b	Robot-assisted gait training (Lokomat) with Virtual reality may not have a difference in efficacy when compared to Robot-assisted gait training (Lokomat) for improving spasticity.	1	Calabrò et al. 2017
1b	Botox (250U) With Robot- Assisted Gait Therapy may not have a difference in efficacy when compared to Botox Alone for improving spasticity.	1	Picelli et al. 2016
1b	Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA) for improving spasticity.	1	Picelli et al. 2015

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Robot Assisted Gait Training may not have a difference in efficacy when compared to Conventional Therapy and Overground Gait Training for improving range of motion.	3	Talaty et al. 2023; Zhang et al. 2023b; Lin et al. 2022a
1b	Exoskeleton Systems may not have a difference in efficacy when compared to Conventional Therapy or Overground Gait Training for improving range of motion.	1	Miyagawa et al. 2023
2	There is conflicting evidence about the effect of Exoskeleton Portable Devices when compared to Overground Gait Training or Stretching or Sham Ankle Foot Orthosis for improving range of motion.	1	Waldman et al. 2013
1b	Exoskeleton Portable Devices may not have a difference in efficacy when compared to Stretching for improving range of motion.	2	Zhai et al. 2021; Forrester et al. 2014
2	Robotic-Assisted Gait Training and Restraint may produce greater improvements in range of motion than Robot-assisted (Lokomat) walking training with arm fixation with conventional care.	1	Bonnyaud et al. 2014a
2	Assist-as-needed robot- assisted gait training for unaffected limb with fully-assisted robot-assisted training for affected limb may not have a difference in efficacy when compared to Assist-as-needed robot- assisted gait training for affected limb with fully-assisted robot-assisted training for unaffected limb for improving range of motion.	1	Seo et al. 2018

2	Robotic-assisted Stretching may produce greater improvements in range of motion than Conventional Therapy.	1	Yoo et al. 2018a
2	Robotics with Treadmill Training and Virtual Reality may not have a difference in efficacy when compared to Seated Training for improving range of motion.	1	Forrester et al. 2016
1b	Ankle robot training low frequency, low intensity may not have a difference in efficacy when compared to ankle robot training high frequency, low intensity or ankle robot training low frequency, high intensity or ankle robot training high frequency, high intensity for improving range of motion.	1	Zhang et al. 2023a
1b	Robot-Guided Ankle Proprioceptive Training with Thermal Stimulation may produce greater improvements in range of motion than Conventional Therapy.	1	Mao et al. 2022b
1b	Dynamic tilt table with robotic leg movement with functional electrical stimulation may not have a difference in efficacy when compared to dynamic tilt table with robotic leg movement for improving range of motion.	1	Ueda et al. 2022
2	Robotic ankle stretching exercises may produce greater improvements in range of motion than Conventional stretching board.	1	Yoo et al. 2018a
2	Botulinum toxin A with Robot assisted Gait Training (RoboGait) and Conventional Physiotherapy may not have a difference in efficacy when compared to Botulinum toxin A with Conventional Physiotherapy or 90min physical therapy 1session/d, 5d/wk, for 3wks for improving range of motion.	1	Erbil et al. 2018
1b	Robot-assisted (Lokomat) gait training with functional electrical stimulation on the ankle dorsiflexor of affected side may not have a difference in efficacy when compared to Robot-assisted (Lokomat) gait training for improving range of motion.	1	Bae et al. 2014

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	There is conflicting evidence about the effect of Robot Assisted Gait Training when compared to Conventional Therapy and Overground Gait Training for improving neurophysiological measures.	1	Zhang et al. 2023b
1b	Early Robot Assisted Gait Training may produce greater improvements in neurophysiological measures than Late Start Robot Assisted Gait Training.	1	Kim et al. 2020a
1b	End-Effector Gait Training may not have a difference in efficacy when compared to Body Weight Supported Treadmill for improving neurophysiological measures.	1	Kim et al. 2020c
1a	Exoskeleton Systems may produce greater improvements in neurophysiological measures than Conventional Therapy or Overground Gait Training.	2	Calabro et al. 2018; Husemann et al. 2007
2	Exoskeleton Systems may produce greater improvements in neurophysiological measures than Treadmill Training.	1	Yoo et al. 2023a
2	Exoskeleton Gait Training may not have a difference in efficacy when compared to Functional Task-Specific Training for improving neurophysiological measures.	1	Jayaraman et al. 2019
2	Exoskeleton Portable Devices may produce greater improvements in neurophysiological measures than Overground Gait Training or Stretching or Sham Ankle Foot Orthosis.	1	Goodman et al. 2014
1b	Robotics Combined with Virtual Reality may produce greater improvements in neurophysiological measures than Robotics,	1	Calabro et al. 2017

	Robotics Combined with Auditory Stimulation or Conventional Training.		
2	Robotic Verticalization with functional electrical stimulation may produce greater improvements in neurophysiological measures than Conventional therapy.	1	Calabro et al. 2015
1b	Robot-Assisted Gait Training with Visuomotor feedback may produce greater improvements in neurophysiological measures than Robot-Assisted Gait Training.	1	Maggio et al. 2021
1b	Healbot T (Exoskeleton) with pelvic motion on may produce greater improvements in neurophysiological measures than Healbot T (Exoskeleton) with pelvic motion off.	1	Son et al. 2021
2	Brain-computer interface- controlled training robot with Conventional Physiotherapy may not have a difference in efficacy when compared to Sham brain-computer interface-controlled training robot with Conventional Physiotherapy for improving neurophysiological measures.	1	Zhao et al. 2022c
1b	Robot-assisted gait training (Lokomat) with Virtual reality may produce greater improvements in neurophysiological measures than Robot-assisted gait training (Lokomat).	1	Calabrò et al. 2017
1b	Robot-assisted gait training and anodal transcranial direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training and sham stimulation for improving neurophysiological measures.	1	Seo et al. 2017
1b	There is conflicting evidence about the effect of Brain-computer interface- operated lower limb rehabilitation robot when compared to Sham (Lower limb pedal training without image, video, sound hint) for improving neurophysiological measures.	1	Li et al. 2021a

AEROBIC MEASURES

1b	Robot-Assisted Gait Training with Visuomotor feedback may not have a difference in efficacy when compared to Robot-Assisted Gait Training for improving cognition.	1	Maggio et al. 2021
2	Haemorrhagic Stroke Erigo Robotic Tilt Table may not have a difference in efficacy when compared to Haemorrhagic Stroke Conventional Care or Ischemic Stroke Conventional Care for improving cognition.	1	Yadav et al. 2020

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Robot Assisted Gait Training may produce greater improvements in upper extremity function than Conventional Therapy and Overground Gait Training.	1	Lee et al. 2019a
2	Exoskeleton Systems may produce greater improvements in upper extremity function than Conventional Therapy or Overground Gait Training.	1	Lee et al. 2019a
1b	Robot-Assisted Gait Training may not have a difference in efficacy when compared to Upper Limb Therapy for improving upper extremity function.	1	Lin et al. 2022b
1b	Brain-computer interface- operated lower limb rehabilitation robot may not have a difference in efficacy when compared to Sham (Lower limb pedal training without image, video, sound hint) for improving upper extremity function.	1	Li et al. 2021a

Key Points

- Robot Assisted Gait Training may be beneficial for improving muscle strength and falls and fear of falling, but not motor recovery, biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy and Overground Gait Training; the literature is mixed regarding neurophysiological measures.
- Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not be beneficial for improving biomechanical gait measures, muscle strength, spasticity, gait endurance, and functional mobility after stroke when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2.5mA).
- Gait Trainer GT I (Rehastim) may not be beneficial for improving motor recovery, gait speed, gait endurance, and functional mobility after stroke when compared to Overground gait training.
- Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation may not be beneficial for improving muscle strength, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Gait Trainer GT II (Rehastim) with Regular rehabilitation.
- Early Robot Assisted Gait Training may be beneficial for improving neurophysiological measures after stroke when compared to Late Start Robot Assisted Gait Training.

- Robot Assisted Gait Training may be beneficial for improving gait endurance, but not biomechanical balance measures, gait speed, functional mobility, and balance, after stroke when compared to Balance Training.
- Electromechanical Gait Training may be beneficial for improving gait speed and functional mobility, but not biomechanical balance measures, activities of daily living, and balance, after stroke when compared to Conventional Treatment or No Treatment; the literature is mixed regarding muscle strength and gait endurance.
- Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy may not be beneficial for improving muscle strength, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Electromechanical gait trainer with Conventional physical therapy.
- Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy may not be beneficial for improving biomechanical balance measures, muscle strength, activities of daily living, gait endurance, functional mobility, and balance after stroke when compared to Electromechanical gait trainer with Conventional therapy.
- End-Effector Gait Training may be beneficial for improving motor recovery, but not neurophysiological measures, gait speed, and functional mobility, after stroke when compared to Body Weight Supported Treadmill.
- Electromechanical gait trainer therapy with Conventional rehabilitation may be beneficial for improving functional mobility, but not motor recovery, spasticity, and gait speed, after stroke when compared to Body weight-supported treadmill training with Conventional rehabilitation.
- Exoskeleton Systems may be beneficial for improving neurophysiological measures and falls and fear of falling, but not motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, aerobic measures, sensory and proprioceptive function, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy or Overground Gait Training; the literature is mixed regarding biomechanical balance measures.
- ExoAtlet exoskeleton exercises with rehabilitation may be beneficial for improving muscle strength, activities of daily living, gait speed, and functional mobility, but not spasticity, after stroke when compared to Ortorent MOTO pedal trainer for active-passive training with rehabilitation; the literature is mixed regarding balance.
- Robot Assisted Gait Training (Lokomat) with Conventional Therapy may be beneficial for improving activities of daily living, gait endurance, functional mobility, and quality of life, but not motor recovery and aerobic measures, after stroke when compared to Robot Assisted Gait Training (Lokomat); the literature is mixed regarding gait speed.
- Resistance load Robotic gait system training may not be beneficial for improving gait speed, gait endurance, and balance after stroke when compared to Assistance Robotic gait system training.
- Therapist-assisted locomotor training may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Robotic-assisted locomotor training.
- Exoskeleton Systems may be beneficial for improving biomechanical gait measures, neurophysiological measures, gait speed, and falls and fear of falling, but not motor recovery, gait endurance, and balance, after stroke when compared to Treadmill Training; the literature is mixed regarding functional mobility.
- 30% weight robot gait training with general physical therapy may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to 50% weight robot gait training with general physical therapy.
- 30% weight robot gait training with general physical therapy may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to 70% weight robot gait training with general physical therapy.
- Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care may be beneficial for improving gait speed, gait endurance, functional mobility, and balance, but not aerobic measures and activities of daily living, after stroke when compared to Physical Activity with Usual physiotherapy.
- Exoskeleton Gait Training may be beneficial for improving gait speed, gait endurance, and balance, but not motor recovery, neurophysiological measures, pain, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Functional Task-Specific Training.

- Exoskeleton Systems Administration Method may be beneficial for improving motor recovery and biomechanical gait measures, but not activities of daily living, functional mobility, and balance, after stroke when compared to Therapist controlled robot-assisted gait training; the literature is mixed regarding gait speed.
- Exoskeleton Portable Devices may be beneficial for improving muscle strength, spasticity, and neurophysiological measures, but not motor recovery, biomechanical gait measures, gait speed, gait endurance, and balance, after stroke when compared to Overground Gait Training or Stretching or Sham Ankle Foot Orthosis; the literature is mixed regarding range of motion and functional mobility.
- Robot-assisted training with Power-assisted ankle robot with Conventional training may be beneficial for improving gait speed, but not functional mobility and balance, after stroke when compared to Robot-assisted training with Swing-controlled ankle robot with Conventional training.
- Exoskeleton Portable Devices may be beneficial for improving gait speed, but not motor recovery, muscle strength, spasticity, range of motion, activities of daily living, and balance, after stroke when compared to Stretching; the literature is mixed regarding biomechanical gait measures.
- Exoskeleton Portable Devices with Ankle Foot Orthosis may be beneficial for improving motor recovery, gait speed, and functional mobility, but not biomechanical gait measures, spasticity, gait endurance, and balance, after stroke when compared to Sham Ankle Foot Orthosis.
- Robotic-Assisted Gait Training and Restraint may be beneficial for improving motor recovery, activities of daily living, balance, and range of motion, but not gait speed, functional mobility, falls and fear of falling, and biomechanical gait measures, after stroke when compared to Robot-assisted (Lokomat) walking training with arm fixation with conventional care.
- Robotics Combined with Virtual Reality may be beneficial for improving motor recovery and neurophysiological measures, but not spasticity, activities of daily living, gait speed, balance, and falls and fear of falling, after stroke when compared to Robotics, Robotics Combined with Auditory Stimulation or Conventional Training; the literature is mixed regarding functional mobility.
- Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may be beneficial for improving motor recovery and muscle strength, but not activities of daily living, gait speed, functional mobility, and balance, after stroke when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.
- Galvanic vestibular stimulation may not be beneficial for improving balance after stroke when compared to Gait training (Lokomat) or Physiotherapy with visual feedback.
- The literature is mixed regarding the effect of Gait training (Lokomat) on balance after stroke when compared to Physiotherapy with visual feedback.
- Assist-as-needed robot- assisted gait training for unaffected limb with fully-assisted robot-assisted training for affected limb may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, range of motion, gait speed, functional mobility, and balance after stroke when compared to Assist-as-needed robot- assisted gait training for affected limb with fully-assisted robot-assisted training for unaffected limb.
- Robot-assisted Trunk Training may be beneficial for improving biomechanical balance measures and balance after stroke when compared to Conventional Therapy.
- Gait training with Gait Exercise Assist Robot (GEAR) may be beneficial for improving functional mobility, but not biomechanical gait measures, gait speed, and quality of life, after stroke when compared to Gait training with treadmill; the literature is mixed regarding gait endurance.
- Gait Training with Gait Exercise Assist Robot (GEAR) may be beneficial for improving activities of daily living, but not motor recovery, after stroke when compared to Overground Gait Training.
- Robotic Verticalization with functional electrical stimulation may be beneficial for improving motor recovery, muscle strength, neurophysiological measures, and balance after stroke when compared to Conventional therapy; the literature is mixed regarding aerobic measures and sensory and proprioceptive function.
- Robotic-assisted Stretching may be beneficial for improving biomechanical balance measures and range of motion, but not biomechanical gait measures and gait speed, after stroke when compared to Conventional Therapy.

- Regent Suit with Neuromotor rehabilitation may be beneficial for improving activities of daily living, gait speed, and balance, but not biomechanical gait measures and aerobic measures, after stroke when compared to Neuromotor rehabilitation.
- Vibration on sole of foot may be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Contact on Sole of Foot with No Vibration.
- Robot-Assisted Gait Training with Visuomotor feedback may be beneficial for improving neurophysiological measures, but not quality of life, after stroke when compared to Robot-Assisted Gait Training; the literature is mixed regarding motor recovery.
- Robotics with Treadmill Training and Virtual Reality may be beneficial for improving motor recovery, but not biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, pain, activities of daily living, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Seated Training.
- Robotic gait training with Exoskeleton ExoAthlet with Conventional physiotherapy may be beneficial for improving quality of life, but not activities of daily living and gait endurance, after stroke when compared to Robotic gait training with Lokomat Free-D with Conventional physiotherapy.
- Ankle robot training low frequency, low intensity may not be beneficial for improving motor recovery and range of motion after stroke when compared to ankle robot training high frequency, low intensity or ankle robot training low frequency, high intensity or ankle robot training high frequency, high intensity.
- Robot-Guided Ankle Proprioceptive Training with Thermal Stimulation may be beneficial for improving motor recovery, range of motion, gait speed, and balance after stroke when compared to Conventional Therapy.
- Robot-Assisted Gait Training with Robotic Balance Platform may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, muscle strength, pain, activities of daily living, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Robot-Assisted Gait Training Alone.
- Robot-Assisted Gait Training may be beneficial for improving motor recovery, but not activities of daily living, after stroke when compared to Upper Limb Therapy.
- Robot-Assisted Gait Training with Balance Training may not be beneficial for improving functional mobility, balance, and falls and fear of falling after stroke when compared to Balance Training Alone; the literature is mixed regarding motor recovery.
- Robot-Assisted Gait Training may be beneficial for improving motor recovery and aerobic measures, but not muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Home-Based Exercise Program.
- Ankle-knee-hip Interlimb coordinated humanoid robot + Conventional Physical therapy may not be beneficial for improving motor recovery, biomechanical gait measures, and spasticity after stroke when compared to Gait training + Conventional PT.
- Healbot T (Exoskeleton) with pelvic motion on may be beneficial for improving neurophysiological measures, but not biomechanical gait measures and gait speed, after stroke when compared to Healbot T (Exoskeleton) with pelvic motion off.
- Progressive reducing assistance force during robot-assisted gait training + conventional PT may be beneficial for improving muscle strength, activities of daily living, functional mobility, and balance after stroke when compared to Full assistance force during robot-assisted gait training + conventional PT.
- Gait trainer device (REHA-STIM) may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Conventional rehabilitation (Bobath).
- 2x Lokomat gait training + 1x Conventional PT may not be beneficial for improving motor recovery, muscle strength, spasticity, gait speed, gait endurance, and functional mobility after stroke when compared to 2x Conventional PT + 1x Lokomat gait training.
- Daoyin with Conventional rehab may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional rehab.
- Daoyin with Conventional rehab may not be beneficial for improving motor recovery and balance after stroke when compared to Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab; the literature is mixed regarding activities of daily living.

- High definition transcranial direct current stimulation (dual) with Robot assisted gait training may be beneficial for improving activities of daily living, but not gait speed, functional mobility, and balance, after stroke when compared to Sham High definition transcranial direct current stimulation with Robot assisted gait training; the literature is mixed regarding motor recovery.
- Robotic Gait Training (Lokomat robotic exoskeleton) with Botulinum toxin injection may be beneficial for improving gait speed and gait endurance, but not spasticity, functional mobility, and balance, after stroke when compared to Botulinum toxin injection with Conventional physiotherapy.
- Acupuncture with Gait rehab robot training (AiWalker-I) and Conventional rehab may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Acupuncture with Conventional rehab.
- Robotic balance training with conventional rehabilitation may be beneficial for improving balance, but not motor recovery, biomechanical balance measures, muscle strength, activities of daily living, functional mobility, and falls and fear of falling, after stroke when compared to Conventional training.
- Brain-computer interface- controlled training robot with Conventional Physiotherapy may not be beneficial for improving motor recovery, neurophysiological measures, activities of daily living, and functional mobility after stroke when compared to Sham brain-computer interface-controlled training robot with Conventional Physiotherapy.
- Dynamic tilt table with robotic leg movement with functional electrical stimulation may be beneficial for improving gait speed, but not motor recovery, biomechanical gait measures, and range of motion, after stroke when compared to dynamic tilt table with robotic leg movement.
- Virtual reality augmented robot- assisted gait training with conventional care may not be beneficial for improving activities of daily living, gait speed, functional mobility, balance, and falls and fear of falling after stroke when compared to Robot-assisted gait training with conventional care.
- Brain-computer interface- operated lower limb rehabilitation robot may be beneficial for improving motor recovery, but not functional mobility and balance, after stroke when compared to Sham (Lower limb pedal training without image, video, sound hint); the literature is mixed regarding neurophysiological measures.
- Interactive Dynamic Scalp Acupuncture with lower-limb robot training (SA & LLRT simultaneously) and Basic Treatment may be beneficial for improving motor recovery, biomechanical gait measures, activities of daily living, gait endurance, and balance after stroke when compared to Scalp Acupuncture with Basic Treatment.
- Trunk stability robot training (3DBT-33) with conventional physical therapy may be beneficial for improving motor recovery and balance, but not functional mobility, after stroke when compared to Conventional Physical Therapy.
- Robot-assisted balance exercises may be beneficial for improving sensory and proprioceptive function, but not functional mobility and balance, after stroke when compared to Conventional care.
- Robotic tilt table (Erigo) therapy may be beneficial for improving muscle strength and quality of life after stroke when compared to Conventional physiotherapy.
- The literature is mixed regarding the effect of Haemorrhagic Stroke Erigo Robotic Tilt Table on motor recovery, muscle strength, spasticity, and quality of life after stroke when compared to Haemorrhagic Stroke Conventional Care or Ischemic Stroke Conventional Care.
- Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training may not be beneficial for improving biomechanical gait measures, muscle strength, spasticity, gait speed, and functional mobility after stroke when compared to Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training.
- Robotic Tilt table with Upper extremity exercises may be beneficial for improving muscle strength and quality of life after stroke when compared to Conventional therapy.
- Robotic ankle stretching exercises may be beneficial for improving biomechanical balance measures and range of motion, but not biomechanical gait measures and gait speed, after stroke when compared to Conventional stretching board.
- Robot-assisted gait training with Virtual reality may not be beneficial for improving muscle strength, gait speed, gait endurance, and functional mobility after stroke when compared to Robot-assisted gait training.

- Botulinum toxin A with Robot assisted Gait Training (RoboGait) and Conventional Physiotherapy may be beneficial for improving functional mobility and balance, but not spasticity and range of motion, after stroke when compared to Botulinum toxin A with Conventional Physiotherapy or 90min physical therapy 1session/d, 5d/wk, for 3wks.
- Robot-assisted gait training (Lokomat) with Virtual reality may be beneficial for improving neurophysiological measures and functional mobility, but not spasticity, after stroke when compared to Robot-assisted gait training (Lokomat).
- Robot-assisted gait training and anodal transcranial direct current stimulation over the leg motor cortex area may not be beneficial for improving gait speed and functional mobility after stroke when compared to Robot-assisted gait training only.
- Robot-assisted gait training and anodal transcranial direct current stimulation may not be beneficial for improving motor recovery, muscle strength, neurophysiological measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Robot-assisted gait training and sham stimulation.
- Botox (250U) With Robot- Assisted Gait Therapy may be beneficial for improving gait endurance, but not spasticity, after stroke when compared to Botox Alone.
- Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not be beneficial for improving muscle strength, spasticity, and functional mobility after stroke when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA); Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may result in lesser improvements in biomechanical gait measures and gait endurance when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA).
- Robot-assisted (Lokomat) gait training with functional electrical stimulation on the ankle dorsiflexor of affected side may not be beneficial for improving biomechanical gait measures, range of motion, gait speed, functional mobility, and balance after stroke when compared to Robot-assisted (Lokomat) gait training.
- Anodal transcranial direct current stimulation with Robot- assisted gait training may not be beneficial for improving gait speed, balance, quality of life, biomechanical gait measures, and gait endurance after stroke when compared to Sham transcranial direct current stimulation with Robot- assisted gait training; the literature is mixed regarding functional mobility.
- Anodal transcranial direct current stimulation with Robot- assisted gait training may be beneficial for improving biomechanical gait measures and functional mobility after stroke when compared to Gait training.
- Virtual reality robotic training (computer) may not be beneficial for improving biomechanical gait measures, gait speed, and gait endurance after stroke when compared to Robotic training.
- Lower Limb Robot with Conventional rehab may not be beneficial for improving motor recovery, activities of daily living, and balance after stroke when compared to Daoyin with Lower Limb Robot with Conventional rehab.
- 30% weight robot gait training with general physical therapy may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to Treadmill training with general physical therapy.
- Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- Auditory stimulation with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.

- Robot-assisted gait training with Conventional care may not be beneficial for improving motor recovery, muscle strength, spasticity, activities of daily living, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Conventional gait training with Conventional care in patients with high motricity.
- Robot-assisted gait training with Conventional care may be beneficial for improving activities of daily living, gait endurance, functional mobility, and balance, but not muscle strength, spasticity, and gait speed, after stroke when compared to Conventional gait training with Conventional care in patients with low motricity.
- Overground gait training using E-Go device with Standard Physiotherapy may not be beneficial for improving motor recovery, activities of daily living, gait endurance, functional mobility, and balance after stroke when compared to Overground walking training with Standard Physiotherapy.
- 50% weight robot gait training with general physical therapy may be beneficial for improving gait speed, but not functional mobility and balance, after stroke when compared to Treadmill training with general physical therapy.
- 70% weight robot gait training with general physical therapy may be beneficial for improving gait speed, but not functional mobility and balance, after stroke when compared to Treadmill training with general physical therapy.

Summary of Key Points: Electromechanical and Robotic Devices

Intervention	Control(s)	Function domain(s)	Effect
Robot Assisted Gait Training	Conventional Therapy and Overground Gait Training	Muscle strength, falls and fear of falling	+
Robot Assisted Gait Training	Conventional Therapy and Overground Gait Training	Motor recovery, biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, quality of life	–
Robot Assisted Gait Training	Conventional Therapy and Overground Gait Training	Neurophysiological measures	=
Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2.5mA)	Biomechanical gait measures, muscle strength, spasticity, gait endurance, functional mobility	–
Gait Trainer GT I (Rehastim)	Overground gait training	Motor recovery, gait speed, gait endurance, functional mobility	–
Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation	Gait Trainer GT II (Rehastim) with Regular rehabilitation	Muscle strength, activities of daily living, gait speed, functional mobility, balance	–
Early Robot Assisted Gait Training	Late Start Robot Assisted Gait Training	Neurophysiological measures	+
Robot Assisted Gait Training	Balance Training	Gait endurance	+
Robot Assisted Gait Training	Balance Training	Biomechanical balance measures, gait speed, functional mobility, balance	–
Electromechanical Gait Training	Conventional Treatment or No Treatment	Gait speed, functional mobility	+
Electromechanical Gait Training	Conventional Treatment or No Treatment	Biomechanical balance measures, activities of daily living, balance	–
Electromechanical Gait Training	Conventional Treatment or No Treatment	Muscle strength, gait endurance	=

Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy	Electromechanical gait trainer with Conventional physical therapy	Muscle strength, activities of daily living, gait speed, functional mobility, balance	–
Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy	Electromechanical gait trainer with Conventional therapy	Biomechanical balance measures, muscle strength, activities of daily living, gait endurance, functional mobility, balance	–
End-Effector Gait Training	Body Weight Supported Treadmill	Motor recovery	+
End-Effector Gait Training	Body Weight Supported Treadmill	Neurophysiological measures, gait speed, functional mobility	–
Electromechanical gait trainer therapy with Conventional rehabilitation	Body weight-supported treadmill training with Conventional rehabilitation	Functional mobility	+
Electromechanical gait trainer therapy with Conventional rehabilitation	Body weight-supported treadmill training with Conventional rehabilitation	Motor recovery, spasticity, gait speed	–
Exoskeleton Systems	Conventional Therapy or Overground Gait Training	Neurophysiological measures, falls and fear of falling	+
Exoskeleton Systems	Conventional Therapy or Overground Gait Training	Motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, aerobic measures, sensory and proprioceptive function, activities of daily living, gait speed, gait endurance, functional mobility, balance, quality of life	–
Exoskeleton Systems	Conventional Therapy or Overground Gait Training	Biomechanical balance measures	=
ExoAtlet exoskeleton exercises with rehabilitation	Ortorent MOTO pedal trainer for active-passive training with rehabilitation	Muscle strength, activities of daily living, gait speed, functional mobility	+
ExoAtlet exoskeleton exercises with rehabilitation	Ortorent MOTO pedal trainer for active-passive training with rehabilitation	Spasticity	–
ExoAtlet exoskeleton exercises with rehabilitation	Ortorent MOTO pedal trainer for active-passive training with rehabilitation	Balance	=
Robot Assisted Gait Training (Lokomat) with Conventional Therapy	Robot Assisted Gait Training (Lokomat)	Activities of daily living, gait endurance, functional mobility, quality of life	+
Robot Assisted Gait Training (Lokomat) with Conventional Therapy	Robot Assisted Gait Training (Lokomat)	Motor recovery, aerobic measures	–
Robot Assisted Gait Training (Lokomat) with Conventional Therapy	Robot Assisted Gait Training (Lokomat)	Gait speed	=
Resistance load Robotic gait system training	Assistance Robotic gait system training	Gait speed, gait endurance, balance	–
Therapist-assisted locomotor training	Robotic-assisted locomotor training	Biomechanical gait measures, gait speed	–
Exoskeleton Systems	Treadmill Training	Biomechanical gait measures, neurophysiological measures, gait speed, falls and fear of falling	+
Exoskeleton Systems	Treadmill Training	Motor recovery, gait endurance, balance	–

Exoskeleton Systems	Treadmill Training	Functional mobility	=
30% weight robot gait training with general physical therapy	50% weight robot gait training with general physical therapy	Gait speed, functional mobility, balance	+
30% weight robot gait training with general physical therapy	70% weight robot gait training with general physical therapy	Gait speed, functional mobility, balance	+
Exoskeleton Gait Training	Functional Task-Specific Training	Gait speed, gait endurance, balance	+
Exoskeleton Gait Training	Functional Task-Specific Training	Motor recovery, neurophysiological measures, pain, functional mobility, falls and fear of falling, quality of life	–
Exoskeleton Systems Administration Method	Therapist controlled robot-assisted gait training	Activities of daily living, functional mobility, balance	–
Exoskeleton Systems Administration Method	Therapist controlled robot-assisted gait training	Motor recovery, biomechanical gait measures	+
Exoskeleton Portable Devices	Overground Gait Training or Stretching vs Sham Ankle Foot Orthosis	Muscle strength, spasticity, neurophysiological measures	+
Exoskeleton Portable Devices	Overground Gait Training or Stretching vs Sham Ankle Foot Orthosis	Motor recovery, biomechanical gait measures, gait speed, gait endurance, balance	–
Exoskeleton Portable Devices	Overground Gait Training or Stretching vs Sham Ankle Foot Orthosis	Range of motion, functional mobility	=
Robot-assisted training with Power-assisted ankle robot with Conventional training	Robot-assisted training with Swing-controlled ankle robot with Conventional training	Gait speed	+
Robot-assisted training with Power-assisted ankle robot with Conventional training	Robot-assisted training with Swing-controlled ankle robot with Conventional training	Functional mobility, balance	–
Exoskeleton Portable Devices	Stretching	Gait speed	+
Exoskeleton Portable Devices	Stretching	Motor recovery, muscle strength, spasticity, range of motion, activities of daily living, balance	–
Exoskeleton Portable Devices	Stretching	Biomechanical gait measures	=
Exoskeleton Portable Devices with Ankle Foot Orthosis	Sham Ankle Foot Orthosis	Motor recovery, gait speed, functional mobility	+
Exoskeleton Portable Devices with Ankle Foot Orthosis	Sham Ankle Foot Orthosis	Biomechanical gait measures, spasticity, gait endurance, balance	–
Robotic-Assisted Gait Training and Restraint	Robot-assisted (Lokomat) walking training with arm fixation with conventional care	Motor recovery, activities of daily living, balance, range of motion	+
Robotic-Assisted Gait Training and Restraint	Robot-assisted (Lokomat) walking training with arm fixation with conventional care	Gait speed, functional mobility, falls and fear of falling, biomechanical gait measures	–
Robotic-Assisted Gait Training and Restraint	Robot-assisted (Lokomat) walking training with arm fixation with conventional care	Range of motion	+
Robotic-Assisted Gait Training and Restraint	Robot-assisted (Lokomat) walking training with arm fixation with conventional care	Biomechanical gait measures, gait speed	–

Robotics Combined with Virtual Reality	Robotics, Robotics Combined with Auditory Stimulation or Conventional Training	Motor recovery, neurophysiological measures	+
Robotics Combined with Virtual Reality	Robotics, Robotics Combined with Auditory Stimulation or Conventional Training	Spasticity, activities of daily living, gait speed, balance, falls and fear of falling	–
Robotics Combined with Virtual Reality	Robotics, Robotics Combined with Auditory Stimulation or Conventional Training	Functional mobility	=
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy	Motor recovery, muscle strength	+
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy	Activities of daily living, gait speed, functional mobility, balance	–
Galvanic vestibular stimulation	Gait training (Lokomat) or Physiotherapy with visual feedback	Balance	–
Gait training (Lokomat)	Physiotherapy with visual feedback	Balance	=
Assist-as-needed robot- assisted gait training for unaffected limb with fully-assisted robot-assisted training for affected limb	Assist-as-needed robot- assisted gait training for affected limb with fully-assisted robot- assisted training for unaffected limb	Motor recovery, biomechanical gait measures, muscle strength, range of motion, gait speed, functional mobility, balance	–
Robot-assisted Trunk Training	Conventional Therapy	Biomechanical balance measures, balance	+
Gait training with Gait Exercise Assist Robot (GEAR)	Gait training with treadmill	Functional mobility	+
Gait training with Gait Exercise Assist Robot (GEAR)	Gait training with treadmill	Biomechanical gait measures, gait speed, quality of life	–
Gait training with Gait Exercise Assist Robot (GEAR)	Gait training with treadmill	Gait endurance	=
Gait Training with Gait Exercise Assist Robot (GEAR)	Overground Gait Training	Activities of daily living	+
Gait Training with Gait Exercise Assist Robot (GEAR)	Overground Gait Training	Motor recovery	–
Robotic Verticalization with functional electrical stimulation	Conventional therapy	Motor recovery, muscle strength, neurophysiological measures, balance	+
Robotic Verticalization with functional electrical stimulation	Conventional therapy	Aerobic measures, sensory and proprioceptive function	=
Robotic-assisted Stretching	Conventional Therapy	Biomechanical balance measures, range of motion	+
Robotic-assisted Stretching	Conventional Therapy	Biomechanical gait measures, gait speed	–
Regent Suit with Neuromotor rehabilitation	Neuromotor rehabilitation	Activities of daily living, gait speed, balance	+
Regent Suit with Neuromotor rehabilitation	Neuromotor rehabilitation	Biomechanical gait measures, aerobic measures	–
Vibration on sole of foot	Contact on Sole of Foot with No Vibration	Biomechanical balance measures, falls and fear of falling	+

Robot-Assisted Gait Training with Visuomotor feedback	Robot-Assisted Gait Training	Neurophysiological measures	+
Robot-Assisted Gait Training with Visuomotor feedback	Robot-Assisted Gait Training	Quality of life	–
Robot-Assisted Gait Training with Visuomotor feedback	Robot-Assisted Gait Training	Motor recovery	=
Robotics with Treadmill Training and Virtual Reality	Seated Training	Motor recovery	+
Robotics with Treadmill Training and Virtual Reality	Seated Training	Biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, pain, activities of daily living, gait speed, gait endurance, functional mobility, balance	–
Robotic gait training with Exoskeleton ExoAthlet with Conventional physiotherapy	Robotic gait training with Lokomat Free-D with Conventional physiotherapy	Quality of life	+
Robotic gait training with Exoskeleton ExoAthlet with Conventional physiotherapy	Robotic gait training with Lokomat Free-D with Conventional physiotherapy	Activities of daily living, gait endurance	–
Ankle robot training low frequency, low intensity	ankle robot training high frequency, low intensity or ankle robot training low frequency, high intensity or ankle robot training high frequency, high intensity	Motor recovery, range of motion	–
Robot-Guided Ankle Proprioceptive Training with Thermal Stimulation	Conventional Therapy	Motor recovery, range of motion, gait speed, balance	+
Robot-Assisted Gait Training with Robotic Balance Platform	Robot-Assisted Gait Training Alone	Biomechanical gait measures, biomechanical balance measures, muscle strength, pain, activities of daily living, gait speed, gait endurance, functional mobility, balance	–
Robot-Assisted Gait Training	Upper Limb Therapy	Motor recovery	+
Robot-Assisted Gait Training	Upper Limb Therapy	Activities of daily living	–
Robot-Assisted Gait Training with Balance Training	Balance Training Alone	Functional mobility, balance, falls and fear of falling	–
Robot-Assisted Gait Training with Balance Training	Balance Training Alone	Motor recovery	=
Robot-Assisted Gait Training	Home-Based Exercise Program	Motor recovery, aerobic measures	+
Robot-Assisted Gait Training	Home-Based Exercise Program	Muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance	–
Ankle-knee-hip Interlimb coordinated humanoid robot + Conventional Physical therapy	Gait training + Conventional PT	Motor recovery, biomechanical gait measures, spasticity	–
Healbot T (Exoskeleton) with pelvic motion on	Healbot T (Exoskeleton) with pelvic motion off	Neurophysiological measures	+
Healbot T (Exoskeleton) with pelvic motion on	Healbot T (Exoskeleton) with pelvic motion off	Biomechanical gait measures, gait speed	–

Progressive reducing assistance force during robot-assisted gait training + conventional PT	Full assistance force during robot-assisted gait training + conventional PT	Muscle strength, activities of daily living, functional mobility, balance	+
Gait trainer device (REHA-STIM)	Conventional rehabilitation (Bobath)	Motor recovery, biomechanical gait measures, muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance	–
2x Lokomat gait training + 1x Conventional PT	2x Conventional PT + 1x Lokomat gait training	Motor recovery, muscle strength, spasticity, gait speed, gait endurance, functional mobility	–
Daoyin with Conventional rehab	Conventional rehab	Motor recovery, activities of daily living	+
Daoyin with Conventional rehab	Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab	Motor recovery, balance	–
Daoyin with Conventional rehab	Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab	Activities of daily living	=
High definition transcranial direct current stimulation (dual) with Robot assisted gait training	Sham High definition transcranial direct current stimulation with Robot assisted gait training	Activities of daily living	+
High definition transcranial direct current stimulation (dual) with Robot assisted gait training	Sham High definition transcranial direct current stimulation with Robot assisted gait training	Gait speed, functional mobility, balance	–
High definition transcranial direct current stimulation (dual) with Robot assisted gait training	Sham High definition transcranial direct current stimulation with Robot assisted gait training	Motor recovery	=
Robotic Gait Training (Lokomat robotic exoskeleton) with Botulinum toxin injection	Botulinum toxin injection with Conventional physiotherapy	Gait speed, gait endurance	+
Robotic Gait Training (Lokomat robotic exoskeleton) with Botulinum toxin injection	Botulinum toxin injection with Conventional physiotherapy	Spasticity, functional mobility, balance	–
Acupuncture with Gait rehab robot training (AiWalker-I) and Conventional rehab	Acupuncture with Conventional rehab	Biomechanical gait measures, gait speed, functional mobility	+
Robotic balance training with conventional rehabilitation	Conventional training	Balance	+
Robotic balance training with conventional rehabilitation	Conventional training	Motor recovery, biomechanical balance measures, muscle strength, activities of daily living, functional mobility, falls and fear of falling	–
Brain-computer interface- controlled training robot with Conventional Physiotherapy	Sham brain-computer interface-controlled training robot with Conventional Physiotherapy	Motor recovery, neurophysiological measures, activities of daily living, functional mobility	–
Dynamic tilt table with robotic leg movement with functional electrical stimulation	dynamic tilt table with robotic leg movement	Gait speed	+
Dynamic tilt table with robotic leg movement with functional electrical stimulation	dynamic tilt table with robotic leg movement	Motor recovery, biomechanical gait measures, range of motion	–

Virtual reality augmented robot-assisted gait training with conventional care	Robot-assisted gait training with conventional care	Activities of daily living, gait speed, functional mobility, balance, falls and fear of falling	−
Brain-computer interface- operated lower limb rehabilitation robot	Sham (Lower limb pedal training without image, video, sound hint)	Motor recovery	+
Brain-computer interface- operated lower limb rehabilitation robot	Sham (Lower limb pedal training without image, video, sound hint)	Functional mobility, balance	−
Interactive Dynamic Scalp Acupuncture with lower-limb robot training (SA & LLRT simultaneously) and Basic Treatment	Scalp Acupuncture with Basic Treatment	Motor recovery, biomechanical gait measures, activities of daily living, gait endurance, balance	+
Trunk stability robot training (3DBT-33) with conventional physical therapy	Conventional Physical Therapy	Motor recovery, balance	+
Trunk stability robot training (3DBT-33) with conventional physical therapy	Conventional Physical Therapy	Functional mobility	−
Robot-assisted balance exercises	Conventional care	Sensory and proprioceptive function	+
Robot-assisted balance exercises	Conventional care	Functional mobility, balance	−
Robotic tilt table (Erigo) therapy	Conventional physiotherapy	Muscle strength, quality of life	+
Haemorrhagic Stroke Erigo Robotic Tilt Table	Haemorrhagic Stroke Conventional Care or Ischemic Stroke Conventional Care	Motor recovery, muscle strength, spasticity, quality of life	=
Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training	Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training	Biomechanical gait measures, muscle strength, spasticity, gait speed, functional mobility	−
Robotic Tilt table with Upper extremity exercises	Conventional therapy	Muscle strength, quality of life	+
Robotic ankle stretching exercises	Conventional stretching board	Biomechanical balance measures, range of motion	+
Robotic ankle stretching exercises	Conventional stretching board	Biomechanical gait measures, gait speed	−
Robot-assisted gait training with Virtual reality	Robot-assisted gait training	Muscle strength, gait speed, gait endurance, functional mobility	−
Botulinum toxin A with Robot assisted Gait Training (RoboGait) and Conventional Physiotherapy	Botulinum toxin A with Conventional Physiotherapy or 90min physical therapy 1session/d, 5d/wk, for 3wks	Functional mobility, balance	+
Botulinum toxin A with Robot assisted Gait Training (RoboGait) and Conventional Physiotherapy	Botulinum toxin A with Conventional Physiotherapy or 90min physical therapy 1session/d, 5d/wk, for 3wks	Spasticity, range of motion	−
Robot-assisted gait training (Lokomat) with Virtual reality	Robot-assisted gait training (Lokomat)	Neurophysiological measures, functional mobility	+
Robot-assisted gait training (Lokomat) with Virtual reality	Robot-assisted gait training (Lokomat)	Spasticity	−
Robot-assisted gait training and anodal transcranial direct current stimulation over the leg motor cortex area	Robot-assisted gait training only	Gait speed, functional mobility	−

Robot-assisted gait training and anodal transcranial direct current stimulation	Robot-assisted gait training and sham stimulation	Motor recovery, muscle strength, neurophysiological measures, gait speed, gait endurance, functional mobility, balance	–
Botox (250U) With Robot- Assisted Gait Therapy	Botox Alone	Gait endurance	+
Botox (250U) With Robot- Assisted Gait Therapy	Botox Alone	Spasticity	–
Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA)	Muscle strength, spasticity, functional mobility	–
Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA)	Biomechanical gait measures, gait endurance	–
Robot-assisted (Lokomat) gait training with functional electrical stimulation on the ankle dorsiflexor of affected side	Robot-assisted (Lokomat) gait training	Biomechanical gait measures, range of motion, gait speed, functional mobility, balance	–
Anodal transcranial direct current stimulation with Robot- assisted gait training	Sham transcranial direct current stimulation with Robot- assisted gait training	Gait speed, balance, quality of life, biomechanical gait measures, gait endurance	–
Anodal transcranial direct current stimulation with Robot- assisted gait training	Sham transcranial direct current stimulation with Robot- assisted gait training	Functional mobility	=
Anodal transcranial direct current stimulation with Robot- assisted gait training	Sham transcranial direct current stimulation with Robot- assisted gait training	Biomechanical gait measures, gait speed, gait endurance	–
Anodal transcranial direct current stimulation with Robot- assisted gait training	Gait training	Biomechanical gait measures, functional mobility	+
Virtual reality robotic training (computer)	Robotic training	Biomechanical gait measures, gait speed, gait endurance	–
Lower Limb Robot with Conventional rehab	Daoyin with Lower Limb Robot with Conventional rehab	Motor recovery, activities of daily living, balance	–
30% weight robot gait training with general physical therapy	Treadmill training with general physical therapy	Gait speed, functional mobility, balance	+
50% weight robot gait training with general physical therapy	Treadmill training with general physical therapy	Functional mobility, balance	–
Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy	Conventional physical therapy with treadmill training	Muscle strength	+

Auditory stimulation with robot-assisted gait training (Treadmill) with conventional physical therapy	Conventional physical therapy with treadmill training	Muscle strength	+
Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care	Physical Activity with Usual physiotherapy	Aerobic measures, activities of daily living	–
Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care	Physical Activity with Usual physiotherapy	Gait endurance, functional mobility, balance, gait speed	+
Exoskeleton Systems Administration Method	Therapist controlled robot-assisted gait training	Gait speed	=
Robot-assisted gait training with Conventional care	Conventional gait training with Conventional care in patients with high motricity	Motor recovery, muscle strength, spasticity, activities of daily living, gait speed, gait endurance, functional mobility, balance	–
Robot-assisted gait training with Conventional care	Conventional gait training with Conventional care in patients with low motricity	Muscle strength, spasticity, gait speed	–
Robot-assisted gait training with Conventional care	Conventional gait training with Conventional care in patients with low motricity	Activities of daily living, gait endurance, functional mobility, balance	+
Brain-computer interface- operated lower limb rehabilitation robot	Sham (Lower limb pedal training without image, video, sound hint)	Neurophysiological measures	=
Overground gait training using E-Go device with Standard Physiotherapy	Overground walking training with Standard Physiotherapy	Motor recovery, activities of daily living, gait endurance, functional mobility, balance	–

Functional Electrical Stimulation

Adopted from: http://inirehab.com/functional-electrical-stimulation-fes-explained/

Functional electrical stimulation (FES), the integration of neuromuscular electrical stimulation with functional activity or training, was first implemented with the goal of assisting stroke patients with foot drop (Liberson et al., 1961; Peckham & Knutson, 2005). FES is currently used to improve the function of the paretic extremity during various motor tasks (Liberson et al., 1961). FES works through applying short, programmed bursts of current to the nerve and muscles in the affected region to produce muscle contractions in a coordinated way.

A total of 73 RCTs were found that evaluated functional electrical stimulation for lower extremity motor rehabilitation. Ten RCTs compared FES Therapy or Sham Stimulation with Conventional Therapy or Sham Stimulation (Dujovic et al. 2017; Wilkinson et al. 2015; Lairamore et al. 2014; You et al. 2014; Kottink et al. 2007; Yan et al. 2005; Newsam & Baker 2004; Burridge et al. 1997; Bogataj et al. 1995; MacDonell et al. 1994). Ten RCTs compared FES Combined with Gait Training with Gait Training or Conventional Therapy (Mijic et al. 2023; VanBloemendaal et al. 2021; Araki et al. 2020; Sheffler et al. 2015; Spaich et al. 2014; Daly et al. 2011; Embrey et al. 2010; Kojovic et al. 2009; Daly et al. 2006; Cozean et al. 1988). Nine RCTs compared Cycling with FES with Cycling with or without Sham FES or Conventional Therapy (Bustamante Valles et al. 2016; De Sousa et al. 2016; Peri et al. 2016; Bauer et al. 2015; Lo et al. 2012; Ambrosini et al. 2012; Ambrosini et al. 2011; Ferrante et al. 2008; Janssen et al. 2008). One RCT compared Interval Cycling + FES with Linear Cycling + FES (Shariat et al. 2021). Six RCTs compared Treadmill Training with FES with Treadmill Training with or without Sham FES (Dantas et al. 2023; Lee et al. 2022d; Awad et al. 2016; Cho et al. 2015c; Hwang et al. 2015; Lee et al. 2013g). Three RCTs compared Robot-assisted Gait Training with FES with Gait Training or Robot-assisted Gait Training (Bae et al. 2014; Tong et al. 2006; Peurala et al. 2005). Two RCTs compared Balance Training + FES with Balance Training or Conventional Care (Lee et al. 2020b; Kunkel et al. 2013). One RCT compared FES + Proprioceptive Neuromuscular Facilitation with Proprioceptive Neuromuscular Facilitation (Shim et al. 2020). Two RCTs compared Ankle Training + BCI-based FES with Ankle Training + FES (Chung et al. 2020b; Chung et al. 2015). Three RCTs compared FES + Tilt Table with Conventional Therapy or Simple Tilt Table (Ueda et al. 2022; Calabro et al. 2015; Solopova et al. 2011 RCT 4). One RCT compared FES + Motor Training on Rocker Board with Conventional Exercises (Cheng et al. 2010). Two RCTs compared FES Muscle Stimulation with Electrical Muscle Stimulation (Mitsutake et al. 2019; Sharif et al. 2017). Two RCTs compared Four-Channel FES with Dual-Channel FES vs Sham (Zheng et al. 2018; Tan et al. 2014). One RCT compared Faradic Electrical Stimulation with Russian Electrical Stimulation (Ganesh et al. 2018). One RCT compared Mirror Therapy with Functional Electrical Stimulation with Conventional Therapy (Salhab et al. 2016). One RCT compared Functional Electrical Stimulation with Transcranial Direct Current Stimulation (Zhang et al. 2021b). One RCT compared Gait Training with FES with Gait Training with tDCS vs Gait Training with tDCS + FES (Mitsutake et al. 2021). Six RCTs compared Peroneal Nerve FES (Foot-drop Stimulator) with Ankle-Foot Orthosis (Sannyasi et al. 2022; Bethoux et al. 2014; Everaert et al. 2013; Kluding et al. 2013; Salisbury et al. 2013; Sheffler et al. 2006). Five RCTs compared Peroneal Nerve FES (Foot-drop Stimulator) with Conventional Therapy or Gait Training (Sehle et al. 2024; Matsumoto et al. 2023; Mao et al. 2022a; Hachisuka et al. 2021; Sheffler et al. 2013). Three RCTs compared Peroneal Nerve Stimulation with

Sham Stimulation or Conventional Therapy (Mrachacz-Kersting et al. 2019; Sheffler et al. 2015; Yavuzer et al. 2007). One RCT compared Core Muscle Training with FES with Core Muscle Training Alone (Li et al. 2024c). One RCT compared FES with Perturbation Training with Perturbation Training Alone (Purohit et al. 2024).

In addition, 16 RCTs in which functional electrical stimulation formed part of a combined or comparative intervention are cross-referenced at the end of Table 28; their primary listings appear in other tables.

The methodological details and results of all 73 RCTs are presented in Table 28.

Table 28. RCTs Evaluating Functional Electrical Stimulation for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
FES vs Conventional Therapy or Sham Stimulation		
Dujovic et al. (2017) RCT (7) Nstart=16 Nend=16 TPS=Subacute A vs 0	E: Multi-pad FES (40Hz) + Conventional stroke rehabilitation C: Conventional Therapy Duration: 30-40min/d, 7d/wk for 4wks – FES; 60min/d 5d/wk for 4wks - Conventional stroke rehabilitation	E vs C: Fugl-Meyer Assessment (-) Berg Balance Scale (-) Barthel Index (-) 10-Metre Walk Test (+exp)
Wilkinson et al. (2015) RCT (7) Nstart=20 Nend=20 TPS=Subacute A vs 0	E: FES + conventional physiotherapy C: Conventional physiotherapy Duration: 60min/session, 12session/6wks	E vs C: 10-Metre Walk Test (-) 6-Minute Walk Test (-) Rivermead Mobility Index (-) Rivermead Visual Gait Analysis (-) Psychosocial Impact of Assistive Devices Scale (-) Hospital Anxiety and Depression Scale (-) Canadian Occupational Performance Measure (-)
Lairamore et al. (2014) RCT (6) Nstart=32 Nend=26 TPS=Acute A vs B	E: Functional Electrical Stimulation + conventional PT C: Sensory (Sham) stimulation + conventional PT Duration: 90min/d, 5d/wk conventional PT & 45min/d, 4d/11d (average) FES/Sham	E vs C: Gait speed (-) EMG TA Activity (-) Functional independence measure Locomotion (-)
You et al. (2014) RCT (6) Nstart=42 Nend=37 TPS=Acute A vs 0	E: Functional Electrical Stimulation (FES) + standard rehabilitation C: standard rehabilitation Duration: 30min/d FES & 60min/d standard rehabilitation, 5d/wk, for 3wks	E vs C: Fugl-Meyer Assessment (+exp) Modified Barthel Index (+exp) Berg Balance Scale (+exp) Postural Assessment Scale for Stroke (-) Composite Spasticity Scale (+exp)
Kottink et al. (2007) RCT (7) Nstart=29 Nend=27 TPS=Chronic A vs 0	E: Implantable 2-channel peroneal nerve stimulator (FES) + conventional care C: Conventional care Duration: 26wk	E vs C: 10-Metre Walk Test (+exp) 6-Minute Walk Test (-) Activity level (-)
Yan et al. (2005) RCT (6)	E1: Standard rehabilitation + FES	E1/E2 vs C: Composite Spasticity Scale (+exp1)

Nstart=46 Nend=41 TPS=Acute A vs 0 vs 0	E2: Standard rehabilitation + Placebo stimulation C: Standard rehabilitation Duration: 60min/d, 5d/wk, for 3wks Standard rehabilitation, 30min/d, 5d/wk, for 3wks FES, 60min/d, 5d/wk, for 3wks Placebo stimulation	EMG co-contraction ratio (+exp1) integrated EMG (+exp1) Max Isometric Voluntary Contraction torque (+exp1) Timed Up & Go (+exp1) %subject Able to Walk (+exp1) E1 vs E2: Composite Spasticity Scale (+exp1) EMG co-contraction ratio (exp1) integrated EMG (+exp1) Max Isometric Voluntary Contraction torque (+exp1) Timed Up & Go (+exp1) %subject Able to Walk (+exp1)
Newsam & Baker (2004) RCT (4) Nstart=19 Nend=19 TPS=Subacute A vs 0	E: FES + Standard physical therapy C: Standard physical therapy Duration: 60min/d, 6d/wk Physical therapy, 5d/wk FES during PT sessions, for 3wks	E vs C: Maximum Voluntary Isometric Torque-Knee Extension (-) Supramaximal Contraction Torque (+exp) Interpolated Twitch Test- Knee Extensor (+exp)
Burridge et al. (1997) RCT (5) Nstart=33 Nend=32 TPS=Chronic A vs 0	E: FES + conventional physiotherapy C: Conventional physiotherapy Duration: 60min/session, 10 sessions/month PT	E vs C: 10-m walk test (+exp) Physiological Cost Index (+exp)
Bogataj et al. (1995) RCT crossover (6) Nstart=20 Nend=20 TPS=Subacute A vs B	E: Multichannel FES C: Customized Conventional Therapy Duration: 60-120min/d, 5d/wk, for 3wks physical therapy & 30- 60min/d, 5d/wk, for 3wks FES	E vs C: Fugl-Meyer score (+exp) Stride length (+exp) Gait speed (+exp) Gait cadence (+exp)
MacDonell et al. (1994) RCT (5) Nstart=38 Nend=38 TPS=Acute A + B vs 0	E: FES physical therapy + Cyclical electrical stimulation C: Conventional physical therapy Duration: 20min/d, 3-5d/wk for 4wks	E vs C: Functional Ambulation Category (-) Barthel Index (-) Fugl-Meyer Assessment (-) Electrophysiological Findings (-)
FES Combined with Gait Training vs Gait Training or Conventional Therapy		
Mijic et al. (2023) RCT crossover (6) Nstart=32 Nend=31 TPS=Acute A vs 0	E: FES during Gait training C: Conventional Physio Duration: 30min/d, 5d/wk, 2wks; No washout	E vs C: MRC (+exp) 10MWT steps (+exp) m/s(-) SEP Latency Paretic P40(-) Paretic N50(-) Non-paretic N50(-)
VanBloemendaal et al. (2021) RCT (8) Nstart=40 Nend=34	E: Gait training + multi-channel functional electrical stimulation C: Conventional gait training Duration: 30min/d, 5d/wk, for 10wks	E vs C: Adherence (-) Satisfaction with treatment (-) Step length symmetry (-)

TPS=Acute A vs 0		Step time asymmetry (-) Single-leg stance time asymmetry (-) Stride length (-) Stride time (-) 10m Walk test (-) Functional gait assessment (-) Berg Balance Scale (-)
Araki et al. (2020) RCT crossover (5) Nstart=14 Nend=14 TPS=Chronic A vs B	E: 14-m walking with FES on gluteus medius and tibialis anterior muscles C: 14-m walking without FES Duration: Single session	E vs C: Gait velocity (+exp) Cadence (-) Stride length (+exp) Range of motion Affected hip (-) Affected knee (-) Affected thigh (-) Affected shank (+exp)
Spaich et al. (2014) RCT (6) Nstart=30 Nend=28 TPS=Subacute A vs 0	E: Physiotherapy-based gait training + FES on foot arch + Conventional Physiotherapy C: Physiotherapy-based gait training + Conventional Physiotherapy Duration: 30min/d, 20d/4wks Physiotherapy-based gait training; 40min/d, 5d/wk, for 4wks Conventional Physiotherapy	E vs C: Functional Ambulation category (-) Walking speed Preferred (-) Maximum (-) Stance time symmetry ratio (-) For those with FAC0 Stance phase (-) Gait cycle (-) For those with FAC1 Stance phase (-) Gait cycle (-) For those with FAC2 Stance phase (+exp) Gait cycle (-)
Daly et al. (2011) RCT (6) Nstart=53 Nend=44 TPS=Chronic A vs 0	E: Gait training + Intramuscular FES C: Gait training Duration: 90min/d, 4d/wk for 12wks	E vs C: Gait assessment and intervention tool score (+exp) Manual Muscle Test (no stats reported/-?) Fugl-Meyer assessment (no stats reported/-?) 6min Walking distance test (no stats reported/-?) Gait speed (no stats reported/-?) Functional Independence Measure Locomotion (no stats reported/-?), -Mobility (no stats reported/-?)
Embrey et al. (2010) RCT crossover (4) Nstart=33 Nend=28 TPS=Chronic A + B vs B Also in Table 7 (Non-Technological Overground Walking and Gait Training)	E: FES of Dorsiflexors and Plantar Flexors + Overground Walking program C: Overground Walking program Duration: 6-8h/d, 7d/wk, for 3mo FES & 1h/d, 6d/wk, for 3mo Walking program	E vs C: 6min Walk Test (+exp) Emory Functional Ambulatory profile (-) Isometric muscle strength of ankle (-) Modified Ashworth scale (-) Stroke Impact scale-16 (+exp)
Kojovic et al. (2009)	E: Gait training + FES	E vs C:

RCT (5) Nstart=13 Nend=13 TPS=Acute A vs 0	C: Gait training Duration: 45min/d, 5d/wk for 4wks	6-Metre Walk Test (+exp) Fugl-Meyer Assessment (+exp) Barthel Index (+exp) Physiological Cost Index (+exp)
Daly et al. (2006) RCT (7) Nstart=32 Nend=29 TPS=Chronic A vs 0	E: Gait training + Functional neuromuscular stimulation with intramuscular electrodes C: Gait training Duration: 90min/d, 4d/wk, for 12wks	E vs C: Tinetti Gait Scale (+exp) Tinetti Balance Scale (-) 6-Minute Walk Test (-) Fugl-Meyer Assessment - Lower Extremity (-) Knee Flexion Coordination (+exp) Self-Reported Functional Milestones (-)
Cozean et al. (1988) RCT (6) Nstart=36 Nend=32 TPS=Chronic A vs B vs A + B vs 0 Also in Table 15 (Biofeedback)	E1: Gait training + FES E2: Gait training + Biofeedback E3: Gait training + FES + Biofeedback C: Standard care Duration: 30min/d, 3d/wk for 6wks	E3 vs E1/E2/C: Gait cycle time (+exp3) Stride length (-) Knee flexion (+exp3) Ankle flexion (+exp3)
Cycling with FES vs Cycling with or without Sham FES or Conventional Therapy		
Bustamante Valles et al. (2016) RCT (3) Nstart=27 Nend=20 TPS=Chronic A + B vs 0 Also in Table 8 (Cycle Ergometer Training); Table 27 (Electromechanical and Robotic Devices)	E: Circuit Training (NESS L300 & Motomed Viva 2 FES+ Cycling & Brain trainer) C: Conventional Therapy Duration: 2hrs, 24 sessions over 6-8wks	E vs C: Fugl-Meyer Assessment (+exp) 6-Minute Walk Test (-) 10-Meter Walk Test (-) Timed Up and Go Test (-)
De Sousa et al. (2016) RCT (8) Nstart=40 Nend=40 TPS=Subacute A + B vs 0 Also in Table 8 (Cycle Ergometer Training)	E: Cycling + FES + conventional care C: Conventional care Duration: 32min/d of FES cycling + 1h conventional therapy 5d/wk, for 4wks experimental group, 60min conventional therapy in control	E vs C: Functional Independence Measure (-) Muscle Strength Affected Leg Knee Extensors (-) Unaffected Leg Knee Extensors (-) Manual Muscle Testing of Key of Affected LE Muscles (+exp) Maximal Force (-) Modified Tardieu Scale for Plantar Flexors o Affected Leg (-)
Peri et al. (2016) RCT (7) Nstart=16 Nend=16 TPS=Acute A + B vs 0 Also in Table 8 (Cycle Ergometer Training)	E: Active cycling + FES C: Physiotherapy Duration: 75min/d, 5d/wk for 3wks	E vs C: Mechanical Efficiency Index (+exp) 6-Minute Walk Test (-) Functional Independence Measure Motor (-) Cognitive (-) Gait speed (-) Double Support Time (-) Unbalance U Score (-) Area Symmetry Index (-) Work Produced by Paretic Leg (-)

Bauer et al. (2015) RCT (7) Nstart=40 Nend=40 TPS=Subacute A + B vs A Also in Table 8 (Cycle Ergometer Training)	E: Active Leg Cycling + FES (unilaterally on the paretic lower limb) C: Active Leg Cycling Duration: 20min/d, 3d/wk for 4wks Cycling	E vs C: Functional Ambulation Category (+exp) Performance-Oriented Mobility Assessment (+exp) Motricity Index (-) Modified Ashworth Scale (-) Gait speed (+con)
Lo et al. (2012) RCT (4) Nstart=20 Nend=20 TPS=Chronic A + B vs B Also in Table 8 (Cycle Ergometer Training)	E: Functional electrical stimulation + cycling C: Cycling Duration: 20 min single session	E vs C: Limits of stability Reaction time Forward (-) Backward (-) Affected (-) Unaffected (-) Movement velocity Forward (+con) Backward (-) Affected (-) Unaffected (-) Directional control Forward (+exp) Backward (-) Affected (-) Unaffected (-) Endpoint excursion Forward (+con) Backward (-) Affected (-) Unaffected (-) Maximum excursion Forward (+exp) Backward (-) Affected (-) Unaffected (-) Muscle tone H/M ratio (-) Relaxation index (-)

Park & Kang (2013a) RCT (5) Nstart=20 Nend=20 TPS=Chronic A + B vs A Primary listing: Table 18 (Action Observation)	E: Gait training + FES + Action observation C: Gait training + FES Duration: 15min/d, 5d/wk for 6wks	E vs C: Weight distribution Right Left (+exp) Anterior Posterior (-) Stability index (+exp) Gait speed (+exp)

Ng et al. (2008) RCT (6) Nstart=54 Nend=50 TPS=Acute A + B vs A vs C Primary listing: Table 27 (Electromechanical and Robotic Devices)	E1: Gait Trainer GT II (Rehastim) + Functional electrical stimulation + Regular rehabilitation E2: Gait Trainer GT II (Rehastim) + Regular rehabilitation C: Overground gait training Duration: 20min/d, 5d/wk, for 4wks intervention sessions & 130min/d, 5d/wk, for 4wks Regular rehabilitation	E1 vs E2: Elderly Mobility Scale (-) Berg Balance Scale (-) Functional Ambulatory Category (-) Motricity Index (-) Functional Independence Measure (-) Barthel Index (-) 5-m Gait Speed (-) E1/E2 vs C: Elderly Mobility Scale (+exp1, +exp2) Berg Balance Scale (-) Functional Ambulatory Category (+exp1) Motricity Index (-) Functional Independence Measure (-) Barthel Index (-) 5-m Gait Speed (+exp1, +exp2)
Baricich et al. (2008) RCT (6) Nstart=23 Nend=23 TPS=Chronic A + B vs A + C vs A + D Primary listing: Table 46 (Botulinum Toxin)	E1: Botulinum toxin A (500U) + FES E2: Botulinum toxin A (500U) + Taping E3: Botulinum toxin A (500U) + Stretching Duration: 30min/session, 2sessions/d, 5d FES & 5d taping & 30min/session, 2sessions/d for 7d stretching	E1 vs E2 vs E3: Modified Ashworth Scale (-) Passive Range of Motion (-) Motor Action Potential (-) Max Dorsiflexion Angle in Stance Phase (-)
Johnson et al. (2004) RCT (6) Nstart=21 Nend=18 TPS=Chronic A + B vs 0 Primary listing: Table 46 (Botulinum Toxin)	E: Botulinum toxin type A injection + FES + Conventional physiotherapy C: Conventional physiotherapy Duration: 1 injection (400U) each into gastrocnemius and tibialis posterior, 1/d, 7d/wk, for 12wks FES, 30-45min/d, 2-3d/wk, for 12wks PT	E vs C: Walking Speed (+exp) Physiological Cost Index (+exp) Modified Ashworth Scale (-) Rivermead Motor Assessment (-) SF-36 (-)
Cozean et al. (1988) RCT (6) Nstart=36 Nend=32 TPS=Chronic A vs B vs A + B vs 0 Primary listing: Table 15 (Biofeedback)	E1: Rehabilitation + EMG biofeedback E2: Rehabilitation + Functional electrical stimulation E3: Rehabilitation + EMG biofeedback + Functional electrical stimulation C: Conventional rehabilitation Duration: 30min/d, 3d/wk for 6wk	E1/E2/E3 vs C: Knee flexion (+exp3) Ankle dorsiflexion (+exp3) Stride length (-) Cycle time (+exp3)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

Other Associated Outcome Measures

MOOD			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Functional electrical stimulation Therapy or Sham Stimulation may not have a difference in efficacy when compared to Conventional Therapy or Sham Stimulation for improving mood.	1	Wilkinson et al. 2015

FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Functional electrical stimulation with Tilt Table may produce greater improvements in fatigue and sleep than Conventional Therapy or Simple Tilt Table.	1	Calabro et al. 2015

Key Points

- Functional electrical stimulation Therapy or Sham Stimulation may be beneficial for improving biomechanical gait measures, muscle strength, spasticity, neurophysiological measures, aerobic measures, and gait speed, but not motor recovery, activities of daily living, gait endurance, functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy or Sham Stimulation.
- Rehabilitation with functional electrical stimulation may be beneficial for improving muscle strength, spasticity, neurophysiological measures, and functional mobility after stroke when compared to rehabilitation with Placebo stimulation.
- Functional electrical stimulation Combined with Gait Training may be beneficial for improving range of motion, aerobic measures, activities of daily living, and quality of life, but not biomechanical gait

measures, spasticity, neurophysiological measures, gait speed, functional mobility, and balance, after stroke when compared to Gait Training or Conventional Therapy; the literature is mixed regarding motor recovery, muscle strength, and gait endurance.

- Cycling with functional electrical stimulation may be beneficial for improving motor recovery, but not biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, aerobic measures, activities of daily living, gait speed, gait endurance, and balance, after stroke when compared to Cycling with or without Sham functional electrical stimulation or Conventional Therapy; the literature is mixed regarding functional mobility.
- Interval Cycling with functional electrical stimulation may be beneficial for improving spasticity and range of motion, but not gait speed and balance, after stroke when compared to Linear Cycling with functional electrical stimulation; the literature is mixed regarding functional mobility.
- Treadmill Training with functional electrical stimulation may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, functional mobility, and balance after stroke when compared to Treadmill Training with or without Sham functional electrical stimulation; the literature is mixed regarding muscle strength and gait endurance.
- Robot-assisted Gait Training with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, muscle strength, range of motion, activities of daily living, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Gait Training or Robot-assisted Gait Training.
- Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy may not be beneficial for improving muscle strength, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Electromechanical gait trainer with Conventional physical therapy.
- Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy may not be beneficial for improving biomechanical balance measures, muscle strength, activities of daily living, gait endurance, functional mobility, and balance after stroke when compared to Electromechanical gait trainer with Conventional therapy.
- Balance Training with functional electrical stimulation may be beneficial for improving neurophysiological measures and balance, but not biomechanical gait measures and gait speed, after stroke when compared to Balance Training or Conventional Care; the literature is mixed regarding functional mobility.
- Functional electrical stimulation with Proprioceptive Neuromuscular Facilitation may not be beneficial for improving functional mobility and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Ankle Training with brain-computer interface-based functional electrical stimulation may be beneficial for improving gait speed, but not biomechanical gait measures, balance, and functional mobility, after stroke when compared to Ankle Training with functional electrical stimulation.
- Functional electrical stimulation with Tilt Table may be beneficial for improving motor recovery, muscle strength, neurophysiological measures, activities of daily living, gait speed, and balance, but not biomechanical gait measures and range of motion, after stroke when compared to Conventional Therapy or Simple Tilt Table; the literature is mixed regarding aerobic measures and sensory and proprioceptive function.
- Functional electrical stimulation with Motor Training on Rocker Board may be beneficial for improving spasticity and functional mobility, but not biomechanical balance measures, muscle strength, range of motion, and gait speed, after stroke when compared to Conventional Exercises.
- Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy may not be beneficial for improving biomechanical balance measures and gait speed after stroke when compared to Electromyography triggered neuromuscular electrical stimulation training (single electrical stimulation) with conventional physiotherapy.
- Functional electrical stimulation Muscle Stimulation may be beneficial for improving motor recovery, spasticity, gait speed, functional mobility, and balance, but not biomechanical balance measures, after stroke when compared to Electrical Muscle Stimulation.

- Four-channel functional electrical stimulation with physiotherapy may be beneficial for improving activities of daily living and balance, but not motor recovery, after stroke when compared to Dual-channel functional electrical stimulation with physiotherapy.
- Four-Channel functional electrical stimulation may be beneficial for improving activities of daily living and balance, but not functional mobility, after stroke when compared to Dual-Channel functional electrical stimulation or Sham; the literature is mixed regarding motor recovery.
- Four-channel functional electrical stimulation with Conventional therapy may be beneficial for improving motor recovery and activities of daily living, but not functional mobility and balance, after stroke when compared to Dual-channel functional electrical stimulation with Conventional therapy.
- Faradic electrical stimulation with Task-oriented exercise may be beneficial for improving spasticity, but not functional mobility, after stroke when compared to Russian electrical stimulation with Task-oriented exercises; the literature is mixed regarding range of motion.
- Faradic Electrical Stimulation may not be beneficial for improving range of motion and functional mobility after stroke when compared to Russian Electrical Stimulation; the literature is mixed regarding spasticity.
- Mirror Therapy with Functional Electrical Stimulation may be beneficial for improving motor recovery, range of motion, and gait speed after stroke when compared to Conventional Therapy.
- Transcranial direct current stimulation with conventional therapy may be beneficial for improving motor recovery, activities of daily living, and functional mobility, but not neurophysiological measures, after stroke when compared to Functional electrical stimulation with conventional therapy.
- Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation with conventional rehabilitation.
- Gait training with transcranial direct current stimulation with conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation.
- Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation.
- Ankle foot orthosis with gait training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility, but not aerobic measures, after stroke when compared to functional electrical stimulation with gait training.
- Peroneal Nerve functional electrical stimulation (Foot-drop Stimulator) may not be beneficial for improving motor recovery, aerobic measures, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Ankle-Foot Orthosis.
- Peroneal Nerve functional electrical stimulation (Foot-drop Stimulator) may not be beneficial for improving motor recovery, biomechanical gait measures, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Conventional Therapy or Gait Training; the literature is mixed regarding spasticity and range of motion.
- Peroneal Nerve Stimulation may not be beneficial for improving biomechanical gait measures, spasticity, range of motion, neurophysiological measures, activities of daily living, gait speed, and functional mobility after stroke when compared to Sham Stimulation or Conventional Therapy; the literature is mixed regarding motor recovery.
- Core Muscle Training with functional electrical stimulation may be beneficial for improving muscle strength, gait speed, and balance after stroke when compared to Core Muscle Training Alone; the literature is mixed regarding functional mobility.
- FES with Perturbation Training may be beneficial for improving biomechanical gait measures and falls and fear of falling after stroke when compared to Perturbation Training Alone.
- Over-Ground Gait Training + BWS Treadmill Training + Functional electrical stimulation with intramuscular electrodes may not be beneficial for improving biomechanical gait measures after stroke when compared to Over-Ground Gait Training + BWS Treadmill Training.

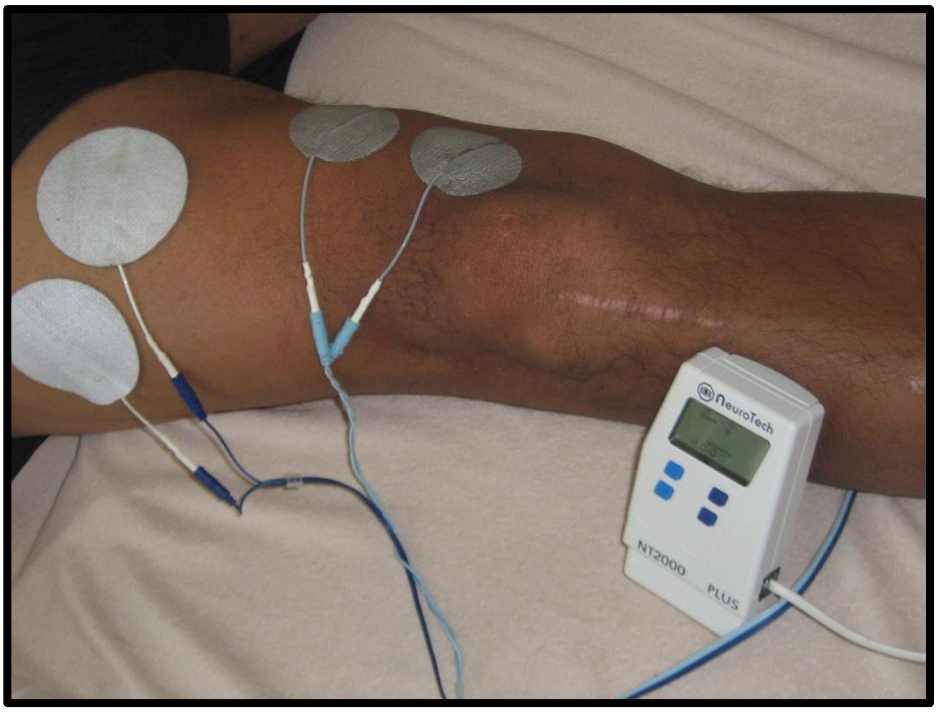
- Mirror feedback with functional electrical stimulation may be beneficial for improving motor recovery, biomechanical gait measures, balance, and falls and fear of falling after stroke when compared to Conventional rehab with functional electrical stimulation.
- Bicephalic transcranial direct current stimulation with gait training and foot drop stimulator (Walkaide orthosis) may not be beneficial for improving motor recovery, neurophysiological measures, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with gait training and foot drop stimulator.
- Contralaterally controlled functional electrical stimulation with rehab may not be beneficial for improving range of motion, neurophysiological measures, activities of daily living, gait speed, and functional mobility after stroke when compared to Neuromuscular electrical stimulaion (neuromuscular electrical stimulation) with rehab; the literature is mixed regarding motor recovery.
- M1 anodal transcranial direct current stimulation with functional electrical stimulation and Conventional care may be beneficial for improving spasticity and balance after stroke when compared to 20min/d functional electrical stimulation with Conventional care or 20min/d functional electrical stimulation and 20min/d conventional care, 5d/wk, for 2wks; the literature is mixed regarding neurophysiological measures.
- Bicephalic Transcranial direct-current stimulation with Footdrop stimulator and Treadmill gait training may not be beneficial for improving spasticity, gait endurance, functional mobility, and quality of life after stroke when compared to Sham transcranial direct-current stimulation with Footdrop stimulator and treadmill gait training.
- Foot drop stimulator with treadmill training and Basic rehabilitation training may be beneficial for improving biomechanical gait measures, spasticity, range of motion, neurophysiological measures, and functional mobility after stroke when compared to Foot drop stimulator training with Basic rehabilitation training.
- Modified Dynamic Ankle Foot Orthosis (including functional electrical stimulation) with Conventional physiotherapy may be beneficial for improving gait speed after stroke when compared to Conventional physiotherapy.
- Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation) may be beneficial for improving biomechanical balance measures, but not neurophysiological measures and balance, after stroke when compared to Functional electric stimulation (functional electrical stimulation).
- Mirror therapy with Functional electrical stimulation may be beneficial for improving motor recovery, range of motion, and gait speed after stroke when compared to Conventional therapy or 50 min, 4d/wk, for 2wks CT 1wk washout.
- Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer) may be beneficial for improving motor recovery, but not gait speed, gait endurance, and functional mobility, after stroke when compared to Conventional Care.
- Gait training with functional electrical stimulation and Action observation may be beneficial for improving biomechanical balance measures and gait speed after stroke when compared to Gait training with functional electrical stimulation.
- Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation may not be beneficial for improving muscle strength, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Gait Trainer GT II (Rehastim) with Regular rehabilitation.
- Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation may be beneficial for improving functional mobility, but not muscle strength, activities of daily living, and balance, after stroke when compared to Overground gait training.
- Botulinum toxin A (500U) with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, spasticity, and range of motion after stroke when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching.
- Botulinum toxin type A injection with functional electrical stimulation and Conventional physiotherapy may be beneficial for improving aerobic measures and gait speed, but not motor recovery, spasticity, and quality of life, after stroke when compared to Conventional physiotherapy.

- Rehabilitation with electromyography biofeedback may be beneficial for improving range of motion after stroke when compared to Conventional rehabilitation; the literature is mixed regarding biomechanical gait measures.
- Customized unilateral ankle-foot orthosis may be beneficial for improving functional mobility after stroke when compared to No Intervention.
- Four-channel functional electrical stimulation (FES) with Standard physiotherapy may be beneficial for improving activities of daily living after stroke when compared to Sham FES with Standard physiotherapy.
- Dual-channel FES with Standard physiotherapy may be beneficial for improving activities of daily living after stroke when compared to Sham FES with Standard physiotherapy.
- Common peroneal nerve stimulation may not be beneficial for improving neurophysiological measures after stroke when compared to Low Frequency rTMS.

Summary of Key Points: Functional Electrical Stimulation

Intervention	Control(s)	Function domain(s)	Effect
Functional electrical stimulation Therapy or Sham Stimulation	Conventional Therapy or Sham Stimulation	Biomechanical gait measures, muscle strength, spasticity, neurophysiological measures, aerobic measures, gait speed	+
Functional electrical stimulation Therapy or Sham Stimulation	Conventional Therapy or Sham Stimulation	Motor recovery, activities of daily living, gait endurance, functional mobility, balance, quality of life	–
Rehabilitation with functional electrical stimulation	rehabilitation with Placebo stimulation	Muscle strength, spasticity, neurophysiological measures, functional mobility	+
Functional electrical stimulation Combined with Gait Training	Gait Training or Conventional Therapy	Range of motion, aerobic measures, activities of daily living, quality of life	+
Functional electrical stimulation Combined with Gait Training	Gait Training or Conventional Therapy	Biomechanical gait measures, spasticity, neurophysiological measures, gait speed, functional mobility, balance	–
Functional electrical stimulation Combined with Gait Training	Gait Training or Conventional Therapy	Motor recovery, muscle strength, gait endurance	=
Cycling with functional electrical stimulation	Cycling with or without Sham functional electrical stimulation or Conventional Therapy	Motor recovery	+
Cycling with functional electrical stimulation	Cycling with or without Sham functional electrical stimulation or Conventional Therapy	Biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, aerobic measures, activities of daily living, gait speed, gait endurance, balance	–
Cycling with functional electrical stimulation	Cycling with or without Sham functional electrical stimulation or Conventional Therapy	Functional mobility	=
Interval Cycling with functional electrical stimulation	Linear Cycling with functional electrical stimulation	Spasticity, range of motion	+
Interval Cycling with functional electrical stimulation	Linear Cycling with functional electrical stimulation	Gait speed, balance	–
Interval Cycling with functional electrical stimulation	Linear Cycling with functional electrical stimulation	Functional mobility	=
Treadmill Training with functional electrical stimulation	Treadmill Training with or without Sham functional electrical stimulation	Motor recovery, biomechanical gait measures, gait speed, functional mobility, balance	+

Treadmill Training with functional electrical stimulation	Treadmill Training with or without Sham functional electrical stimulation	Muscle strength, gait endurance	=
Robot-assisted Gait Training with functional electrical stimulation	Gait Training or Robot-assisted Gait Training	Biomechanical gait measures, biomechanical balance measures, muscle strength, range of motion, activities of daily living, gait speed, gait endurance, functional mobility, balance	–
Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy	Electromechanical gait trainer with Conventional physical therapy	Muscle strength, activities of daily living, gait speed, functional mobility, balance	–
Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy	Electromechanical gait trainer with Conventional therapy	Biomechanical balance measures, muscle strength, activities of daily living, gait endurance, functional mobility, balance	–
Balance Training with functional electrical stimulation	Balance Training or Conventional Care	Neurophysiological measures, balance	+
Balance Training with functional electrical stimulation	Balance Training or Conventional Care	Biomechanical gait measures, gait speed	–
Balance Training with functional electrical stimulation	Balance Training or Conventional Care	Functional mobility	=
Functional electrical stimulation with Proprioceptive Neuromuscular Facilitation	Proprioceptive Neuromuscular Facilitation	Functional mobility, balance	–
Ankle Training with brain-computer interface-based functional electrical stimulation	Ankle Training with functional electrical stimulation	Gait speed	+
Ankle Training with brain-computer interface-based functional electrical stimulation	Ankle Training with functional electrical stimulation	Biomechanical gait measures, balance, functional mobility	–
Functional electrical stimulation with Tilt Table	Conventional Therapy or Simple Tilt Table	Motor recovery, muscle strength, neurophysiological measures, activities of daily living, gait speed, balance	+
Functional electrical stimulation with Tilt Table	Conventional Therapy or Simple Tilt Table	Biomechanical gait measures, range of motion	–
Functional electrical stimulation with Tilt Table	Conventional Therapy or Simple Tilt Table	Aerobic measures, sensory and proprioceptive function	=
Functional electrical stimulation with Motor Training on Rocker Board	Conventional Exercises	Spasticity, functional mobility	+
Functional electrical stimulation with Motor Training on Rocker Board	Conventional Exercises	Biomechanical balance measures, muscle strength, range of motion, gait speed	–
Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy	Electromyography triggered neuromuscular electrical stimulation training (single electrical stimulation) with conventional physiotherapy	Biomechanical balance measures, gait speed	–
Functional electrical stimulation Muscle Stimulation	Electrical Muscle Stimulation	Motor recovery, spasticity, gait speed, functional mobility, balance	+
Functional electrical stimulation Muscle Stimulation	Electrical Muscle Stimulation	Biomechanical balance measures	–



Four-channel functional electrical stimulation with physiotherapy	Dual-channel functional electrical stimulation with physiotherapy	Activities of daily living, balance	+
Four-channel functional electrical stimulation with physiotherapy	Dual-channel functional electrical stimulation with physiotherapy	Motor recovery	−
Four-Channel functional electrical stimulation	Dual-Channel functional electrical stimulation vs Sham	Balance, activities of daily living	+
Four-channel functional electrical stimulation with Conventional therapy	Dual-channel functional electrical stimulation with Conventional therapy	Motor recovery, activities of daily living	+
Four-channel functional electrical stimulation with Conventional therapy	Dual-channel functional electrical stimulation with Conventional therapy	Functional mobility, balance	−
Four-Channel functional electrical stimulation	Dual-Channel functional electrical stimulation vs Sham	Functional mobility, motor recovery	−
Faradic electrical stimulation with Task-oriented exercise	Russian electrical stimulation with Task-oriented exercises	Spasticity	+
Faradic electrical stimulation with Task-oriented exercise	Russian electrical stimulation with Task-oriented exercises	Functional mobility	−
Faradic electrical stimulation with Task-oriented exercise	Russian electrical stimulation with Task-oriented exercises	Range of motion	=
Faradic Electrical Stimulation	Russian Electrical Stimulation	Range of motion, functional mobility	−
Faradic Electrical Stimulation	Russian Electrical Stimulation	Spasticity	=
Mirror Therapy with Functional Electrical Stimulation	Conventional Therapy	Motor recovery, range of motion, gait speed	+
Transcranial direct current stimulation with conventional therapy	Functional electrical stimulation with conventional therapy	Motor recovery, activities of daily living, functional mobility	+
Transcranial direct current stimulation with conventional therapy	Functional electrical stimulation with conventional therapy	Neurophysiological measures	−
Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation	Gait training with transcranial direct current stimulation with conventional rehabilitation	Biomechanical gait measures, gait speed	−
Gait training with transcranial direct current stimulation with conventional rehabilitation	Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation	Biomechanical gait measures, gait speed	−
Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation	Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation	Biomechanical gait measures, gait speed	−
Ankle foot orthosis with gait training	functional electrical stimulation with gait training	Biomechanical gait measures, gait speed, gait endurance, functional mobility	+
Ankle foot orthosis with gait training	functional electrical stimulation with gait training	Aerobic measures	−
Peroneal Nerve functional electrical stimulation (Foot-drop Stimulator)	Ankle-Foot Orthosis	Motor recovery, aerobic measures, gait speed, gait endurance, functional mobility, balance, quality of life	−
Peroneal Nerve functional electrical stimulation (Foot-drop Stimulator)	Ankle-Foot Orthosis	Functional mobility	−

Peroneal Nerve functional electrical stimulation (Foot-drop Stimulator)	Conventional Therapy or Gait Training	Motor recovery, biomechanical gait measures, gait speed, gait endurance, functional mobility, balance, quality of life	–
Peroneal Nerve functional electrical stimulation (Foot-drop Stimulator)	Conventional Therapy or Gait Training	Spasticity, range of motion	=
Peroneal Nerve Stimulation	Sham Stimulation or Conventional Therapy	Biomechanical gait measures, spasticity, range of motion, neurophysiological measures, activities of daily living, gait speed, functional mobility	–
Peroneal Nerve Stimulation	Sham Stimulation or Conventional Therapy	Motor recovery	=
Core Muscle Training with functional electrical stimulation	Core Muscle Training Alone	Muscle strength, gait speed, balance	+
Core Muscle Training with functional electrical stimulation	Core Muscle Training Alone	Functional mobility	=
FES with Perturbation Training	Perturbation Training Alone	Biomechanical gait measures, falls and fear of falling	+
Over-Ground Gait Training + BWS Treadmill Training + Functional electrical stimulation with intramuscular electrodes	Over-Ground Gait Training + BWS Treadmill Training	Biomechanical gait measures	–
Mirror feedback with functional electrical stimulation	Conventional rehab with functional electrical stimulation	Motor recovery, biomechanical gait measures, balance, falls and fear of falling	+
Bicephalic transcranial direct current stimulation with gait training and foot drop stimulator (Walkaide orthosis)	Sham transcranial direct current stimulation with gait training and foot drop stimulator	Motor recovery, neurophysiological measures, functional mobility	–
Contralaterally controlled functional electrical stimulation with rehab	Neuromuscular electrical stimulaion (neuromuscular electrical stimulation) with rehab	Range of motion, neurophysiological measures, activities of daily living, gait speed, functional mobility	–
Contralaterally controlled functional electrical stimulation with rehab	Neuromuscular electrical stimulaion (neuromuscular electrical stimulation) with rehab	Motor recovery	=
M1 anodal transcranial direct current stimulation with functional electrical stimulation and Conventional care	20min/d functional electrical stimulation with Conventional care or 20min/d functional electrical stimulation and 20min/d conventional care, 5d/wk, for 2wks	Spasticity, balance	+
M1 anodal transcranial direct current stimulation with functional electrical stimulation and Conventional care	20min/d functional electrical stimulation with Conventional care or 20min/d functional electrical stimulation and 20min/d conventional care, 5d/wk, for 2wks	Neurophysiological measures	=
Bicephalic Transcranial direct-current stimulation with Footdrop stimulator and Treadmill gait training	Sham transcranial direct-current stimulation with Footdrop stimulator and treadmill gait training	Spasticity, gait endurance, functional mobility, quality of life	–
Foot drop stimulator with treadmill training and Basic rehabilitation training	Foot drop stimulator training with Basic rehabilitation training	Biomechanical gait measures, spasticity, range of motion, neurophysiological measures, functional mobility	+

Modified Dynamic Ankle Foot Orthosis (including functional electrical stimulation) with Conventional physiotherapy	Conventional physiotherapy	Gait speed	+
Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation)	Functional electric stimulation (functional electrical stimulation)	Biomechanical balance measures	+
Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation)	Functional electric stimulation (functional electrical stimulation)	Neurophysiological measures, balance	–
Mirror therapy with Functional electrical stimulation	Conventional therapy or 50 min, 4d/wk, for 2wks CT 1wk washout	Motor recovery, range of motion, gait speed	+
Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer)	Conventional Care	Motor recovery	+
Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer)	Conventional Care	Gait speed, gait endurance, functional mobility	–
Gait training with functional electrical stimulation and Action observation	Gait training with functional electrical stimulation	Biomechanical balance measures, gait speed	+
Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation	Gait Trainer GT II (Rehastim) with Regular rehabilitation	Muscle strength, activities of daily living, gait speed, functional mobility, balance	–
Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation	Overground gait training	Functional mobility	+
Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation	Overground gait training	Muscle strength, activities of daily living, balance	–
Botulinum toxin A (500U) with functional electrical stimulation	Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching	Biomechanical gait measures, spasticity, range of motion	–
Botulinum toxin type A injection with functional electrical stimulation and Conventional physiotherapy	Conventional physiotherapy	Aerobic measures, gait speed	+
Botulinum toxin type A injection with functional electrical stimulation and Conventional physiotherapy	Conventional physiotherapy	Motor recovery, spasticity, quality of life	–
Rehabilitation with electromyography biofeedback	Conventional rehabilitation	Range of motion	+
Rehabilitation with electromyography biofeedback	Conventional rehabilitation	Biomechanical gait measures	=
Customized unilateral ankle-foot orthosis	No Intervention	Functional mobility	+
Four-channel functional electrical stimulation (FES) with Standard physiotherapy	Sham FES with Standard physiotherapy	Activities of daily living	+
Dual-channel FES with Standard physiotherapy	Sham FES with Standard physiotherapy	Activities of daily living	+
Common peroneal nerve stimulation	Low Frequency rTMS	Neurophysiological measures	–

Four-Channel functional electrical stimulation	Dual-Channel functional electrical stimulation or Sham	Activities of daily living, balance	+
Four-Channel functional electrical stimulation	Dual-Channel functional electrical stimulation or Sham	Functional mobility	−
Four-Channel functional electrical stimulation	Dual-Channel functional electrical stimulation or Sham	Motor recovery	=

Neuromuscular Electrical Stimulation (NMES)

Adopted from: https://swordsphysio.ie/physiotherapy-treatments/neuromuscular-stimulation/

Neuromuscular electrical stimulation (NMES) is a technique used to generate muscle contractions in regions affected by hemiparesis by stimulating lower motor neurons involved in muscle movement through transcutaneous application of electrical currents (Allen & Goodman, 2014; Monte-Silva et al., 2019).

1. Cyclic NMES in which a muscle is repetitively stimulated at near maximum contraction on a pre-set schedule and patient participation is passive (Nascimento et al., 2014). 2. Electromyography (EMG) triggered NMES, in which a target muscle is directly controlled or triggered by volitional EMG activity from the target or a different muscle to elicit a desired stimulation (Monte-Silva et al., 2019).

Interferential current therapy (ICT) is a variation of NMES that uses two medium frequency currents to create a 100Hz interference wave across the skin which exerts its maximal effect deeper in the tissue of the treatment area (Goats, 1990).

A total of 22 RCTs were found that evaluated neuromuscular electrical stimulation (NMES) for lower extremity motor rehabilitation. One RCT compared Cyclic NMES with Conventional Therapy or Neurodevelopmental Techniques (Bakhtiary & Fatemy 2008). Four RCTs compared NMES Therapy with Conventional Therapy (Joy et al. 2024; Bilek et al., 2020; Yang et al. 2018; Yavuzer et al. 2006b). One RCT compared EMG-triggered NMES with Conventional Therapy (Mesci et al. 2009). One RCT compared Interferential Current NMES with Air-pump Massage with Sham (Suh et al. 2014a). One RCT compared Cyclic NMES with Passive Movement Training (Yamaguchi et al. 2012). One RCT compared Cyclic NMES with Trunk/Core Training (Ko et al. 2016). One RCT evaluated Comparison of Cyclic NMES Stimulation Intensity (Wang et al. 2016b). Three RCTs compared Contralaterally Controlled NMES with Cyclic NMES or NMES (Shen et al. 2022; Huang et al. 2022c; Knutson et al. 2013). Two RCTs compared Mirror Therapy with Cyclic NMES with Conventional Therapy (Xu et al. 2017; Lee et al. 2016). One RCT compared NMES Therapy with Mirror Therapy (Pagilla et al. 2019). One RCT compared NMES with Exercise

Therapy with Exercise Therapy (Busk et al. 2021). One RCT compared NMES with Walking Training with Conventional Walking Training with Ankle-Foot Orthosis (Morone et al. 2012b). One RCT evaluated NMES with Botulinum Toxin Type A (Baricich et al. 2019). One RCT compared NMES with Passive Ankle Movement Training with NMES Alone (Cho et al. 2022a). One RCT compared NMES Stimulation with Sham Stimulation (Almutairi et al. 2023).

In addition, ten RCTs in which neuromuscular electrical stimulation (NMES) formed part of a combined or comparative intervention are cross-referenced at the end of Table 29; their primary listings appear in other tables.

The methodological details and results of all 22 RCTs are presented in Table 29.

Table 29. RCTs Evaluating Neuromuscular Electrical Stimulation (NMES) for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Cyclic NMES vs Conventional Therapy or Neurodevelopmental Techniques		
Bakhtiary & Fatemy (2008) RCT (8) Nstart=40 Nend=35 TPS=Not reported A + B vs B Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)	E: Cyclic NMES + Bobath C: Bobath Approach Duration: 15min/d bobath & 9min/d NMES, 20d	E vs C: PROM ankle dorsiflexion (+exp) Ankle Dorsiflexion Muscle Manual Test (+exp) Hmax/Mmax Ratio (-) Modified Ashworth Scale(+exp)
NMES vs Conventional Therapy		
Joy et al. (2024) Feasibility/pilot RCT (3) Nstart=36 Nend=36 TPS=Chronic A vs 0	E: Russian current therapy + conventional physiotherapy C: Conventional physiotherapy Duration: 10min/d, 5d/wk, 6wks	E vs C: 10MWT (+exp) BRS (+exp)
Bilek et al. (2020) RCT (5) Nstart=60 Nend=60 TPS=Subacute A vs 0	E: NMES (50Hz) + conventional care C: Conventional care Duration: 45min/d of conventional care, 20min/d of NMES, 5d/wk for 6wks	E vs C: Follow-up (at wk 6) results: Brunnel balance assessment (-) Functional Ambulation classification (-) Adapted Patient Evaluation and Conference system (-) Postural assessment scale for stroke patients (+exp) Short Form-36 (-) Mini-Mental state examination (-) Stroke Rehabilitation Movement Assessment (+exp)
Yang et al. (2018) RCT (6) Nstart=25 Nend=25 TPS=Chronic A + B vs C + B vs D + B	E1: Neuromuscular electrical stimulation (NMES) on tibialis anterior + ambulation training E2: NMES on medial gastrocnemius + ambulation training C: Stretching & ROM exercise + ambulation training	E1/E2 vs C: Walking velocity (-) Cadence (-) Step length affected (-) Step length unaffected (-) Spatial asymmetry (+exp1) Temporal asymmetry (+exp2)

	Duration: 20min/d NMES or stretching & 15min/d ambulation training, 3d/wk, for 7wks	Ankle dorsiflexion strength (+exp1) Ankle plantarflexion strength (-) Modified Ashworth Scale (-) Spasticity Index (-) CV of ankle dorsiflexion at HS (-) CV of ankle plantarflexion in push off (-) MP of dorsiflexion at HS (-) MP of plantarflexion in push off (+exp1) E1 vs E2: Walking velocity (-) Cadence (-) Step length affected (-) Step length unaffected (-) Spatial asymmetry (-) Temporal symmetry (-) Ankle dorsiflexion strength (-) Ankle plantarflexion strength (-) Modified Ashworth Scale (-) Spasticity Index (+exp1) CV of ankle dorsiflexion at HS (-) CV of ankle plantarflexion in push off (-) MP of dorsiflexion at HS (-) MP of plantarflexion in push off (-)
Yavuzer et al. (2006b) RCT (7) Nstart=25 Nend=25 TPS=Subacute A vs 0	E: NMES + Conventional rehabilitation C: Conventional rehabilitation Duration: 10min/d, 5d/wk, for 4wks NMES, 2-5hr/d, 5d/wk, for 4wks Conventional rehabilitation EMG-triggered NMES	E vs C: Brunnstrom Stage for Lower Extremity (-) Walking Velocity (-) Step Length (-) Stance Phase (-) Pelvis/Hip/Knee/Ankle Sagittal Plane Total Excursion (-) Maximum Ankle DF at Swing (-) Maximum Ankle PF at Initial Contact (-) vs Stretching
EMG-triggered NMES vs Conventional Therapy		
Mesci et al. (2009) RCT (6) Nstart=40 Nend=40 TPS=Chronic A vs 0	E: EMG-triggered NMES C: Conventional therapy Duration: 20min/d, 5d/wk, for 4wks NMES & 5d/wk, for 4wks conventional therapy	E vs C: Ankle passive dorsiflexion range of motion (-) modified Ashworth scale (-) Brunnstrom Stage (-) Functional independence measurement (-) Functional Ambulation Categories (-) Rivermead motor assessment score (-)
Interferential Current NMES with Air-pump Massage vs Sham		
Suh et al. (2014a) RCT (6) Nstart=42 Nend=42 TPS=Chronic A + B vs B Also in Table 53 (Acupuncture and Massage)	E: Interferential current therapy (ICT) stimulation of gastrocnemius + air-pump massage + standard rehabilitation C: Placebo-ICT + air-pump massage + standard rehabilitation Duration: 60min/session, 1 session ICT & 30min/session, 1 session standard rehabilitation	E vs C: Modified Ashworth Scale (+exp) Functional Reach Test (+exp) Berg Balance Scale (+exp) Timed Up and Go (+exp) 10-meter walk test (+exp)

Cyclic NMES vs Passive Movement Training		
Yamaguchi et al. (2012) RCT (8) Nstart=27 Nend=27 TPS=Subacute A + B vs B vs A	E1: Passive Movement Training + cyclic NMES E2: Cyclic NMES E3: Passive Movement Training Duration: 20min, 1session	E1/E2 vs E3: 10-m walk test (+exp1) modified Ashworth scale (-) E1 vs E2: 10-m walk test (+exp1) modified Ashworth scale (-)
Cyclic NMES vs Trunk/Core Training		
Ko et al. (2016) RCT (6) Nstart=34 Nend=30 TPS=Acute A + B vs A vs B Also in Table 4 (Trunk Training)	E1: Trunk NMES + Core muscle training E2: Trunk NMES C: Core Training Duration: 20min/d, 3d/wk, for 3wks	E1 vs C: Trunk Impairment Scale (-) Dynamic Sitting Balance (+exp1) Berg Balance Scale (+exp1) Postural Assessment for Stroke Scale (-) Modified Barthel Index (-) E1 vs E2: Trunk Impairment Scale (-) Dynamic Sitting Balance (-) Berg Balance Scale (+exp1) Postural Assessment for Stroke Scale (-) Modified Barthel Index (-)
Comparison of Cyclic NMES Stimulation Intensity		
Wang et al. (2016b) RCT (6) Nstart=72 Nend=66 TPS=Acute A1 vs A2 vs B vs 0	E1: Sensory threshold NMES + Conventional therapy E2: Motor threshold NMES + Conventional therapy E3: Full-movement NMES + Conventional therapy C: Conventional therapy Duration: 60min/d, 5d/wk, for 4wks NMES	E3 vs E1/E2/C: Composite Spasticity Scale (+exp3) Ankle active dorsiflexion (+exp3) Timed Up & Go Test (-)
Contralaterally Controlled NMES vs Cyclic NMES or NMES		
Shen et al. (2022) RCT (9) Nstart=44 Nend=42 TPS=Subacute A1 vs A2	E1: Contralaterally controlled NMES + conventional therapy E2: NMES + conventional therapy Duration: 15min/d, 5d/wk for 3wks	E1 vs E2: FMA-LE (+exp) MBI (+exp) average EMG (-) integrated EMG (-) root mean square (+exp)
Huang et al. (2022c) RCT (7) Nstart=70 Nend=60 TPS=Subacute A vs B Also in Table 28 (Functional Electrical Stimulation)	E: Contralaterally controlled functional electrical stimulation (CCFES) + Routine rehab C: Neuromuscular electrical stimulaion (NMES) + Routine rehab Duration: 80min (20min stimulation + 60min CT)/d 5d/wk, 3 wks	E vs C: Ankle Dorsiflexion AROM (-) FMA-LE (+exp) FMA-LE Subcategories Reflex Activity (-) Flexor Synergy (-) Extensor Synergy (+exp) Movement Combining Synergy (+exp) Movement Out of Synergy (+exp) Normal Reflexes (-) Coordination/speed (-) BI (-) FAC (-) 10 Meter walking test (-) Surface EMG Root Mean Square of Paretic Tibialis Anterior(-)

Knutson et al. (2013) RCT (6) Nstart=26 Nend=24 TPS=Chronic A vs B	E: Contralaterally controlled NMES (self-administered at home) + Conventional gait training C: Cyclic NMES (self- administered at home) + Conventional gait training Duration: 51min, 2x/d, 5d/wk, for 6wks self-administered NMES & 45min/d, 2d/wk, for 6wks conventional gait training	E vs C: Fugl-Meyer assessment (-) Maximum dorsiflexion angle (-) Ankle movement tracking error (-) Maximum isometric dorsiflexion (-) Modified Emory Functional Ambulation profile (-) Gait velocity (-) Dorsiflexion angle (-) Peak knee flexion in swing (-) Peak hip flexion in swing (-) Stride length (-) Cadence (-)
Mirror Therapy with Cyclic NMES vs Conventional Therapy		
Xu et al. (2017) RCT (7) Nstart=69 Nend=69 TPS=Subacute A + B vs A vs 0 Also in Table 19 (Mirror Therapy)	E1: Conventional rehabilitation + mirror therapy + NMES E2: Conventional rehabilitation + mirror therapy C: Conventional rehabilitation + Sham mirror therapy Duration: 240min/d, 5d/wk, for 4wks conventional rehabilitation + 30min/d mirror/sham/mirror+NMES	E1/E2 v C: 10-meter walk test (+exp1, +exp2) Brunnstrom stages of lower extremity (+exp1, +exp2) Modified Ashworth Scale (+exp1) Passive ROM (+exp1, +exp2) E1 v E2: 10-meter walk test (+exp1) Brunnstrom stages of lower extremity (-) Modified Ashworth Scale (-) Passive ROM (-)
Lee et al. (2016) RCT (6) Nstart=30 Nend=27 TPS=Chronic A + B vs 0 Also in Table 19 (Mirror Therapy)	E: Mirror therapy + cyclical NMES + conventional physical therapy C: Conventional therapy Duration: 60min/d, 5d/wk, for 4wks conventional PT & 1x/d, 5d/wk, for 4wks MT + NNES	E vs C: Ankle Dorsiflexor Strength (+exp) Modified Ashworth Scale (-) Berg Balance Scale (+exp) Timed-up-and-go (-) 6-minute Walk Test (-)
NMES vs Mirror Therapy		
Pagilla et al. (2019) RCT (8) Nstart=30 Nend=30 TPS=Acute A vs B	E: NMES + Conventional Therapy C: Mirror Therapy + Conventional Therapy Duration: conventional for 60min, mirror/NMES for 30min, 6 consecutive days	E vs C: Berg Balance Scale (-) Barthel Index (-) Fugl-Meyer Assessment (-)
NMES with Exercise Therapy vs Exercise Therapy		
Busk et al. (2021) RCT (7) Nstart=50 Nend=47 TPS=Acute A vs 0	E: Neuromuscular electrical stimulation + Exercise therapy C: Exercise therapy Duration: 10min/d, 5d/wk, for 2wks	E vs C: Fugl-Meyer Assessment (-) 6 min walk test (-) 10 m Walk Test (-) Guralnik Timed Standing Balance (-) Sit to Stand (-) Timed Up and Go (-) EQ-5D-5L (-) Montreal Cognitive Assessment (-) Becks Depression Inventory (-)

NMES with Walking Training vs Conventional Walking Training with Ankle-Foot Orthosis		
Morone et al. (2012b) RCT (5) Nstart=20 Nend=20 TPS=Acute A vs B	E: NMES (Walkaide) + walking training + conventional therapy C: Walking training + ankle- foot-orthosis + conventional therapy Duration: 40min/d, 5d/wk, for 4wks Walking training with NMES or AFO & 40min/d, 5d/wk, for 4wks conventional therapy	E vs C: 10-Metre Walk Test (+exp) Functional Ambulation Classification (+exp) Barthel Index (-) Rivermead Mobility Index (-) Medical Research Council Scale (-) Canadian Neurological Scale (-) Ashworth Scale (-) Manual Muscle Test (-)
NMES with Botulinum Toxin Type A		
Baricich et al. (2019) RCT (7) Nstart=30 Nend=30 TPS=Chronic A1 + B vs A2 + B Also in Table 46 (Botulinum Toxin)	E: Botox Injections (50U-120U) + Electrical Stimulation of Antagonist and Injected Agonist Muscles C: Botox Injections (50U-120U) + Electrical Stimulation of Injected Agonist Muscles Duration: E: 1hr single session ES + stretching 20min + 1hr/d, 5d ES of Tibialis anterior + conventional physical therapy 1h/d, 5d C: 1hr single session ES + stretching 20min + conventional physical therapy 1h/d, 5d	E vs C: 10-Meter Walk Test (-) Modified Ashworth Scale (-) Passive Range of Motion (-) Medical Research Council (-) 2-Minute Walk Test (-)
NMES with Passive Ankle Movement Training vs NMES Alone		
Cho et al. (2022a) RCT (7) Nstart=35 Nend=30 TPS=Chronic A1 vs A2	E: Electrical stimulation therapy with Passive biaxial ankle movement training + conventional rehabilitation C: Electrical stimulation therapy + conventional rehabilitation Duration: 40 min/d, 5d/wk, 4wks stimulation with ankle movement + 90 min/day, 5d/wk,4wks conventional rehab	E vs C: Proprioception Dorsiflexion (-) plantarflexion (-) supination (-) pronation (-) Passive range of motion Dorsiflexion (-) plantarflexion (-) supination (+exp) pronation (+exp) Strength Dorsiflexion (+exp) plantarflexion (-) supination (-) pronation (-) FMA-LE (-) Berg balance scale (-) TUG (-) Fall efficacy scale (-) Walking speed (-) step length (-) step time (-) step width (-) Joint range of motion (-)
NMES vs Sham Stimulation		
Almutairi et al. (2023) Feasibility/pilot RCT (7) Nstart=19	E: Active NMES C: Sham NMES Duration: 30min/d, 3d/wk, 4wks	E vs C: MAS (+exp) 10MWT (-)

Nend=19 TPS=Chronic A vs 0		FAC (-)
Additional Comparisons from the Source Dataset		
Chen et al. (2005) RCT (7) Nstart=24 Nend=24 TPS=Chronic A vs 0	E: Neuromuscular electrical stimulation (NMES) C: Sham NMES Duration: 20min/d, 6d/wk, 4wks	E vs C: modified Ashworth Scale(No stats) H-reflex latency (No stats) recovery curve (No stats) Tibial fmax/Mmax ratio (No stats) 10-meter walking test (No stats)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Xu et al. (2024) RCT (8) Nstart=35 Nend=35 TPS=Chronic A vs 0 Primary listing: Table 31 (Muscle Vibration)	E: Whole-body vibration + conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) C: Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) Duration: E: 230min/d, 6d/wk, 4wks; C: 200min/d, 6d/wk, 4 wks	E vs C: BBS(-) Functional Reach Test (-) Romberg's test of balance length (-) area(-) Ankle joint dorsiflexion-plantar flexion (DP)(+exp) Ankle joint inversion-eversion (+exp)
Lee (2022e) RCT (7) Nstart=44 Nend=41 TPS=Chronic A1 vs A2 Primary listing: Table 8 (Cycle Ergometer Training)	E: EMG-triggered Pedaling training C: Pedaling training Duration: 50min/d, 5d/wk for 4wks	E vs C: Velocity (+exp) Cadence (-) Stride time (-) Step time affected side (+exp) unaffected side (-) Single Limb Support time affected side (+exp) unaffected side (-) Double limb support (+exp) Stride Length (+exp) Step length affected (+exp) unaffected (+exp) Gait symmetery step length (-) step time (+exp) FMA-LE (+exp) Changes in Muscle Activation of Affected side: Rectus Femoris Muscle (+exp) Biceps Femoris muscle (+exp) Tibialis Anterior Muscle (-) Gastrocnemius Muscle (+exp) Changes in Muscle Activation of Unaffected side: Rectus Femoris Muscle (-) Biceps Femoris muscle (-)

		Tibialis Anterior Muscle (-) Gastrocnemius Muscle (-) Symmetry Ratio: Rectus Femoris Muscle (+exp) Biceps Femoris muscle (+exp) Tibialis Anterior Muscle (-) Gastrocnemius Muscle (+exp)
Shim et al. (2020) RCT (4) Nstart=40 Nend=33 TPS=Chronic A + B vs A Primary listing: Table 12 (Stretching or Mobilization Exercises)	E: Proprioceptive neuromuscular facilitation (PNF) trunk pattern + EMG-triggered FES C: proprioceptive neuromuscular facilitation (PNF) trunk pattern Duration: 30min/d, 5d/wk, 4wks	E vs C: Trunk impairment scale (-) Berg balance scale (-) Dynamic gait index (-)
Mitsutake et al. (2019) RCT (6) Nstart=41 Nend=36 TPS=Subacute A + B vs A vs 0 Primary listing: Table 28 (Functional Electrical Stimulation)	E1: Electromyography-triggered neuromuscular electrical stimulation + tilt sensor functional electrical stimulation training (combined electrical stimulation) + conventional physiotherapy E2: Electromyography triggered neuromuscular electrical stimulation training (single electrical stimulation) + conventional physiotherapy C: Conventional rehabilitation Duration: 60min/day, for 2wks	E1 vs E2: 10-meter walking tests (-) Body sway Vertical plane (-) Mediolateral plane (-) Anterioposterior plane (-) E1/E2 vs C: 10-meter walking tests (+exp1) Body sway Vertical plane (-) Mediolateral plane (+exp1) Anterioposterior plane (-)
Yen et al. (2019) RCT (7) Nstart=42 Nend=40 TPS=Acute A vs B vs 0 Primary listing: Table 30 (Transcutaneous Electrical Nerve Stimulation (TENS))	E1: Transcutaneous Nerve Stimulation (TENS) + Standard Early Rehabilitation E2: Neuromuscular Electrical Stimulation (NMES) + Standard Early Rehabilitation C: Standard rehabilitation Duration: 30min/d, 5d/wk, for 2wks TENS, NMES, 30min/d, 5d/wk, for 2wks standard rehabilitation in all groups	E1 vs C: Postural Assessment Scale for Stroke (+exp1) Functional Independence Measure (+exp1) E2 vs C: Postural Assessment Scale for Stroke (-) Functional Independence Measure (-) E1 vs E2 ; Postural Assessment Scale for Stroke (-) Functional Independence Measure (-)
Bae et al. (2017) RCT (6) Nstart=18 Nend=18 TPS=Chronic A + B vs C Primary listing: Table 18 (Action Observation)	E: Dual-afferent sensory input (EMG-triggered FES + Action Observation) C: Functional electric stimulation (FES) Duration: 20min/d, 5d/wk, for 4wks	E vs C: Movement-related Cortical Potential Bereitschafts Potential (-) Negative Slope (-) Motor Potential (+exp) Muscle Activity Tibialis Anterior (-) Medial Gastrocnemius (-) H-reflex (-) Balance Surface Area Ellipse (-) Surface Area Length (-) Limit Of Stability (+exp)
Chen et al. (2017) RCT (8) Nstart=54	E: Tele-supervising rehabilitation (PT+ EMG-NMES) C: Conventional Care	E vs C: modified Barthel Index(-) Berg Balance Scale(-)

Nend=51 TPS=Acute A + B vs 0 Primary listing: Table 25 (Telerehabilitation and Technology-Based Home Exercise Programs)	Duration: 1hr, 2x/d, 5d/wk, for 12 wks PT + 20min, 2x/d, 5d/wk, for 12wks	Caregiver Strain Index (-) Root mean square extensor carpi radialis longus (-) tibialis anterior (-)
Beaulieu et al. (2017) RCT crossover (6) Nstart=15 Nend=15 TPS=Chronic A vs B vs C vs 0 Primary listing: Table 36 (Repetitive Peripheral Magnetic Stimulation)	E1: Neuromuscular Electrical Stimulation E2: Repetitive Peripheral Magnetic Stimulation E3: Muscle Tendon Vibration C: Occupational Therapy Duration: 2.5-3h/d, 1d/wk - 1wk washout, 4wks	E1/E2/E3 vs C: Ankle active motor threshold (+exp2) Intracortical inhibition (+exp2) Isometric Eversion Strength (+exp2, +exp3) Range of Motion (-) Stretch reflex of plantar flexors (-)
Lee et al. (2016) RCT (6) Nstart=30 Nend=27 TPS=Chronic A + B vs 0 Primary listing: Table 19 (Mirror Therapy)	E: Mirror therapy + cyclical neuromuscular electrical stimulation + conventional physical therapy C: Conventional therapy Duration: 60min/d, 5d/wk, for 4wks conventional PT & 1session/d, 5d/wk, for 4wks MT + NNES	E vs C: Ankle Dorsiflexor Strength (+exp) Modified Ashworth Scale (-) Berg Balance Scale (+exp) Timed-up-and-go (-) 6-minute Walk Test (-)
Morone et al. (2012b) RCT (5) Nstart=20 Nend=20 TPS=Acute A vs B Primary listing: Table 13 (Orthotic Devices)	E: NMES (Walkaide) + walking training + conventional therapy C: Walking training + ankle-foot- orthosis + conventional therapy Duration: 40min/d, 5d/wk, 4wks Walking training with NMES or AFO & 40min/d, 5d/wk, 4wks conventional therapy	E vs C: 10-Metre Walk Test (+exp) Functional Ambulation Classification (+exp) Barthel Index (-) Rivermead Mobility Index (-) Medical Research Council Scale (-) Canadian Neurological Scale (-) Ashworth Scale (-) Manual Muscle Test (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Neuromuscular electrical stimulation Therapy when compared to Conventional Therapy for improving motor recovery.	2	Joy et al. 2024; Yavuzer et al. 2006b
1b	Electromyography-triggered neuromuscular electrical stimulation may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	1	Mesci et al. 2009
1b	Contralaterally controlled neuromuscular electrical stimulation with conventional therapy may produce greater improvements in motor	1	Shen et al. 2022

	recovery than neuromuscular electrical stimulation with conventional therapy.		
1a	There is conflicting evidence about the effect of Contralaterally Controlled neuromuscular electrical stimulation when compared to Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation for improving motor recovery.	2	Huang et al. 2022c; Knutson et al. 2013
1b	Mirror Therapy with Cyclic neuromuscular electrical stimulation may not have a difference in efficacy when compared to Conventional Therapy for improving motor recovery.	1	Xu et al. 2017
1b	Neuromuscular electrical stimulation Therapy may not have a difference in efficacy when compared to Mirror Therapy for improving motor recovery.	1	Pagilla et al. 2019
1b	Neuromuscular electrical stimulation with Exercise Therapy may not have a difference in efficacy when compared to Exercise Therapy for improving motor recovery.	1	Busk et al. 2021
2	Neuromuscular electrical stimulation with Walking Training may not have a difference in efficacy when compared to Conventional Walking Training with Ankle-Foot Orthosis for improving motor recovery.	1	Morone et al. 2012b
1b	Neuromuscular electrical stimulation with Passive Ankle Movement Training may not have a difference in efficacy when compared to neuromuscular electrical stimulation Alone for improving motor recovery.	1	Cho et al. 2022a
1b	Electromyography-triggered Pedaling training may produce greater improvements in motor recovery than Pedaling training.	1	Lee 2022e
2	Neuromuscular electrical stimulation (Walkaide) with walking training and conventional therapy may not have a difference in efficacy when compared to Walking training with ankle-foot- orthosis and conventional therapy for improving motor recovery.	1	Morone et al. 2012b

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Neuromuscular electrical stimulation Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving biomechanical gait measures.	2	Yang et al. 2018; Yavuzer et al. 2006b
1b	Neuromuscular electrical stimulation on tibialis anterior with ambulation training may not have a difference in efficacy when compared to neuromuscular electrical stimulation on medial gastrocnemius with ambulation training for improving biomechanical gait measures.	1	Yang et al. 2018
1b	Contralaterally Controlled neuromuscular electrical stimulation may not have a difference in efficacy when compared to Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation for improving biomechanical gait measures.	1	Knutson et al. 2013
1b	Neuromuscular electrical stimulation with Passive Ankle Movement Training may not have a difference in efficacy when compared to neuromuscular electrical stimulation Alone for improving biomechanical gait measures.	1	Cho et al. 2022a
1b	Electromyography-triggered Pedaling training may produce greater improvements in biomechanical gait measures than Pedaling training.	1	Lee 2022e

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy may not have a difference in efficacy when compared to Electromyography triggered neuromuscular electrical stimulation training (single electrical stimulation) with conventional physiotherapy for improving biomechanical balance measures.	1	Mitsutake et al. 2019
1b	Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy may not have a difference in efficacy when compared to Conventional rehabilitation for improving biomechanical balance measures.	1	Mitsutake et al. 2019
1b	Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation) may produce greater improvements in biomechanical balance measures than Functional electric stimulation (functional electrical stimulation).	1	Bae et al. 2017

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Cyclic neuromuscular electrical stimulation may produce greater improvements in muscle strength than Conventional Therapy or Neurodevelopmental Techniques.	1	Bakhtiary & Fatemy 2008
1b	There is conflicting evidence about the effect of Neuromuscular electrical stimulation Therapy when compared to Conventional Therapy for improving muscle strength.	1	Yang et al. 2018
1b	Neuromuscular electrical stimulation on tibialis anterior with ambulation training may not have a difference in efficacy when compared to neuromuscular electrical stimulation on medial gastrocnemius with ambulation training for improving muscle strength.	1	Yang et al. 2018
1b	Contralaterally Controlled neuromuscular electrical stimulation may not have a difference in efficacy when compared to Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation for improving muscle strength.	1	Knutson et al. 2013
1b	Mirror Therapy with Cyclic neuromuscular electrical stimulation may produce greater improvements in muscle strength than Conventional Therapy.	1	Lee et al. 2016
2	Neuromuscular electrical stimulation with Walking Training may not have a difference in efficacy when compared to Conventional Walking Training with Ankle-Foot Orthosis for improving muscle strength.	1	Morone et al. 2012b
1b	Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not have a difference in efficacy when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles for improving muscle strength.	1	Baricich et al. 2019
1b	Neuromuscular electrical stimulation with Passive Ankle Movement Training may not have a difference in efficacy when compared to neuromuscular electrical stimulation Alone for improving muscle strength.	1	Cho et al. 2022a
1b	Neuromuscular Electrical Stimulation may not have a difference in efficacy when compared to Occupational Therapy for improving muscle strength.	1	Beaulieu et al. 2017

1b	Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy may produce greater improvements in muscle strength than Conventional therapy.	1	Lee et al. 2016
2	Neuromuscular electrical stimulation (Walkaide) with walking training and conventional therapy may not have a difference in efficacy when compared to Walking training with ankle-foot- orthosis and conventional therapy for improving muscle strength.	1	Morone et al. 2012b

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Cyclic neuromuscular electrical stimulation may produce greater improvements in spasticity than Conventional Therapy or Neurodevelopmental Techniques.	1	Bakhtiary & Fatemy 2008
1b	Neuromuscular electrical stimulation Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving spasticity.	1	Yang et al. 2018
1b	There is conflicting evidence about the effect of Neuromuscular electrical stimulation on tibialis anterior with ambulation training when compared to neuromuscular electrical stimulation on medial gastrocnemius with ambulation training for improving spasticity.	1	Yang et al. 2018
1b	Electromyography-triggered neuromuscular electrical stimulation may not have a difference in efficacy when compared to Conventional Therapy for improving spasticity.	1	Mesci et al. 2009
1b	Interferential Current neuromuscular electrical stimulation with Air-pump Massage may produce greater improvements in spasticity than Sham.	1	Suh et al. 2014a
1b	Passive Movement Training with cyclic neuromuscular electrical stimulation may not have a difference in efficacy when compared to Passive Movement Training for improving spasticity.	1	Yamaguchi et al. 2012
1b	Passive Movement Training with cyclic neuromuscular electrical stimulation may not have a difference in efficacy when compared to Cyclic neuromuscular electrical stimulation for improving spasticity.	1	Yamaguchi et al. 2012
1b	Sensory threshold neuromuscular electrical stimulation with Conventional therapy may produce greater improvements in spasticity than Conventional therapy.	1	Wang et al. 2016b
1a	Mirror Therapy with Cyclic neuromuscular electrical stimulation may not have a difference in efficacy when compared to Conventional Therapy for improving spasticity.	2	Xu et al. 2017; Lee et al. 2016
2	Neuromuscular electrical stimulation with Walking Training may not have a difference in efficacy when compared to Conventional Walking Training with Ankle-Foot Orthosis for improving spasticity.	1	Morone et al. 2012b
1b	Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not have a difference in efficacy when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles for improving spasticity.	1	Baricich et al. 2019
1b	Neuromuscular electrical stimulation Stimulation may produce greater improvements in spasticity than Sham Stimulation.	1	Almutairi et al. 2023
1b	Neuromuscular electrical stimulation (NMES) may not have a difference in efficacy when compared to Sham NMES for improving spasticity.	1	Chen et al. 2005
1b	Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy may not have a difference in efficacy when compared to Conventional therapy for improving spasticity.	1	Lee et al. 2016

2	Neuromuscular electrical stimulation (Walkaide) with walking training and conventional therapy may not have a difference in efficacy when compared to Walking training with ankle-foot- orthosis and conventional therapy for improving spasticity.	1	Morone et al. 2012b

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Cyclic neuromuscular electrical stimulation may produce greater improvements in range of motion than Conventional Therapy or Neurodevelopmental Techniques.	1	Bakhtiary & Fatemy 2008
1b	Neuromuscular electrical stimulation Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving range of motion.	1	Yang et al. 2018
1b	Neuromuscular electrical stimulation on tibialis anterior with ambulation training may not have a difference in efficacy when compared to neuromuscular electrical stimulation on medial gastrocnemius with ambulation training for improving range of motion.	1	Yang et al. 2018
1b	Electromyography-triggered neuromuscular electrical stimulation may not have a difference in efficacy when compared to Conventional Therapy for improving range of motion.	1	Mesci et al. 2009
1b	Sensory threshold neuromuscular electrical stimulation with Conventional therapy may produce greater improvements in range of motion than Conventional therapy.	1	Wang et al. 2016b
1a	Contralaterally Controlled neuromuscular electrical stimulation may not have a difference in efficacy when compared to Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation for improving range of motion.	2	Huang et al. 2022c; Knutson et al. 2013
1b	Mirror Therapy with Cyclic neuromuscular electrical stimulation may not have a difference in efficacy when compared to Conventional Therapy for improving range of motion.	1	Xu et al. 2017
1b	Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not have a difference in efficacy when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles for improving range of motion.	1	Baricich et al. 2019
1b	Neuromuscular electrical stimulation with Passive Ankle Movement Training may not have a difference in efficacy when compared to neuromuscular electrical stimulation Alone for improving range of motion.	1	Cho et al. 2022a
1b	Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) may produce greater improvements in range of motion than Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy).	1	Xu et al. 2024

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Cyclic neuromuscular electrical stimulation may not have a difference in efficacy when compared to Conventional Therapy or Neurodevelopmental Techniques for improving neurophysiological measures.	1	Bakhtiary & Fatemy 2008

1b	Contralaterally controlled neuromuscular electrical stimulation with conventional therapy may not have a difference in efficacy when compared to neuromuscular electrical stimulation with conventional therapy for improving neurophysiological measures.	1	Shen et al. 2022
1b	Contralaterally Controlled neuromuscular electrical stimulation may not have a difference in efficacy when compared to Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation for improving neurophysiological measures.	1	Huang et al. 2022c
1b	Neuromuscular electrical stimulation (NMES) may not have a difference in efficacy when compared to Sham NMES for improving neurophysiological measures.	1	Chen et al. 2005

Key Points

- Cyclic neuromuscular electrical stimulation may be beneficial for improving muscle strength, spasticity, and range of motion, but not neurophysiological measures, after stroke when compared to Conventional Therapy or Neurodevelopmental Techniques.
- Neuromuscular electrical stimulation Therapy may not be beneficial for improving biomechanical gait measures, spasticity, range of motion, activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Conventional Therapy; the literature is mixed regarding motor recovery, muscle strength, and balance.
- Neuromuscular electrical stimulation on tibialis anterior with ambulation training may not be beneficial for improving biomechanical gait measures, muscle strength, range of motion, and gait speed after stroke when compared to neuromuscular electrical stimulation on medial gastrocnemius with ambulation training; the literature is mixed regarding spasticity.
- Electromyography-triggered neuromuscular electrical stimulation may not be beneficial for improving motor recovery, spasticity, range of motion, activities of daily living, and functional mobility after stroke when compared to Conventional Therapy.
- Interferential Current neuromuscular electrical stimulation with Air-pump Massage may be beneficial for improving spasticity, gait speed, functional mobility, and balance after stroke when compared to Sham.
- Passive Movement Training with cyclic neuromuscular electrical stimulation may be beneficial for improving gait speed, but not spasticity, after stroke when compared to Passive Movement Training.
- Passive Movement Training with cyclic neuromuscular electrical stimulation may be beneficial for improving gait speed, but not spasticity, after stroke when compared to Cyclic neuromuscular electrical stimulation.
- Cyclic neuromuscular electrical stimulation may not be beneficial for improving activities of daily living after stroke when compared to Trunk/Core Training; the literature is mixed regarding balance.
- Trunk neuromuscular electrical stimulation with Core muscle training may not be beneficial for improving activities of daily living and balance after stroke when compared to Trunk neuromuscular electrical stimulation.
- Sensory threshold neuromuscular electrical stimulation with Conventional therapy may be beneficial for improving spasticity and range of motion, but not functional mobility, after stroke when compared to Conventional therapy.
- Contralaterally controlled neuromuscular electrical stimulation with conventional therapy may be beneficial for improving motor recovery and activities of daily living, but not neurophysiological measures, after stroke when compared to neuromuscular electrical stimulation with conventional therapy.
- Contralaterally Controlled neuromuscular electrical stimulation may not be beneficial for improving range of motion, neurophysiological measures, activities of daily living, gait speed, functional mobility, biomechanical gait measures, and muscle strength after stroke when compared to Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation; the literature is mixed regarding motor recovery.
- Mirror Therapy with Cyclic neuromuscular electrical stimulation may be beneficial for improving muscle strength, gait speed, and balance, but not motor recovery, spasticity, range of motion, gait endurance, and functional mobility, after stroke when compared to Conventional Therapy.
- Neuromuscular electrical stimulation Therapy may not be beneficial for improving motor recovery, activities of daily living, and balance after stroke when compared to Mirror Therapy.
- Neuromuscular electrical stimulation with Exercise Therapy may not be beneficial for improving motor recovery, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Exercise Therapy.
- Neuromuscular electrical stimulation with Walking Training may be beneficial for improving gait speed, but not motor recovery, muscle strength, spasticity, and activities of daily living, after stroke when compared to Conventional Walking Training with Ankle-Foot Orthosis; the literature is mixed regarding functional mobility.
- Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not be beneficial for improving muscle strength, spasticity, range of motion, gait speed, and gait endurance after stroke when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles.

- Neuromuscular electrical stimulation with Passive Ankle Movement Training may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, range of motion, sensory and proprioceptive function, gait speed, functional mobility, balance, and falls and fear of falling after stroke when compared to neuromuscular electrical stimulation Alone.
- Neuromuscular electrical stimulation Stimulation may be beneficial for improving spasticity, but not gait speed and functional mobility, after stroke when compared to Sham Stimulation.
- Neuromuscular electrical stimulation (NMES) may not be beneficial for improving spasticity, neurophysiological measures, and gait speed after stroke when compared to Sham NMES.
- Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) may be beneficial for improving range of motion, but not balance, after stroke when compared to Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy).
- Electromyography-triggered Pedaling training may be beneficial for improving motor recovery, biomechanical gait measures, and gait speed after stroke when compared to Pedaling training; the literature is mixed regarding neurophysiological measures.
- Proprioceptive neuromuscular facilitation trunk pattern with electromyography-triggered functional electrical stimulation may not be beneficial for improving functional mobility and balance after stroke when compared to proprioceptive neuromuscular facilitation trunk pattern.
- Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy may not be beneficial for improving biomechanical balance measures and gait speed after stroke when compared to Electromyography triggered neuromuscular electrical stimulation training (single electrical stimulation) with conventional physiotherapy.
- Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy may be beneficial for improving gait speed, but not biomechanical balance measures, after stroke when compared to Conventional rehabilitation.
- Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation may be beneficial for improving activities of daily living and balance after stroke when compared to rehabilitation.
- Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation may not be beneficial for improving activities of daily living and balance after stroke when compared to Neuromuscular Electrical Stimulation with Early Rehabilitation.
- Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation) may be beneficial for improving biomechanical balance measures, but not neurophysiological measures and balance, after stroke when compared to Functional electric stimulation (functional electrical stimulation).
- Tele-supervising rehabilitation (physical therapy with electromyography-neuromuscular electrical stimulation) may not be beneficial for improving activities of daily living, balance, and quality of life after stroke when compared to Conventional Care.
- Neuromuscular Electrical Stimulation may be beneficial for improving neurophysiological measures, but not muscle strength, after stroke when compared to Occupational Therapy.
- Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy may be beneficial for improving muscle strength and balance, but not spasticity, gait endurance, and functional mobility, after stroke when compared to Conventional therapy.
- Neuromuscular electrical stimulation (Walkaide) with walking training and conventional therapy may be beneficial for improving gait speed, but not motor recovery, muscle strength, spasticity, and activities of daily living, after stroke when compared to Walking training with ankle-foot- orthosis and conventional therapy; the literature is mixed regarding functional mobility.

Summary of Key Points: Neuromuscular Electrical Stimulation (NMES)

Intervention	Control(s)	Function domain(s)	Effect
Cyclic neuromuscular electrical stimulation	Conventional Therapy or Neurodevelopmental Techniques	Muscle strength, spasticity, range of motion	+
Cyclic neuromuscular electrical stimulation	Conventional Therapy or Neurodevelopmental Techniques	Neurophysiological measures	−
Neuromuscular electrical stimulation Therapy	Conventional Therapy	Biomechanical gait measures, spasticity, range of motion, activities of daily living, gait speed, functional mobility, quality of life	−
Neuromuscular electrical stimulation Therapy	Conventional Therapy	Motor recovery, muscle strength, balance	=
Neuromuscular electrical stimulation on tibialis anterior with ambulation training	neuromuscular electrical stimulation on medial gastrocnemius with ambulation training	Biomechanical gait measures, muscle strength, range of motion, gait speed	−
Neuromuscular electrical stimulation on tibialis anterior with ambulation training	neuromuscular electrical stimulation on medial gastrocnemius with ambulation training	Spasticity	=
Electromyography-triggered neuromuscular electrical stimulation	Conventional Therapy	Motor recovery, spasticity, range of motion, activities of daily living, functional mobility	−
Interferential Current neuromuscular electrical stimulation with Air-pump Massage	Sham	Spasticity, gait speed, functional mobility, balance	+
Passive Movement Training with cyclic neuromuscular electrical stimulation	Passive Movement Training	Gait speed	+
Passive Movement Training with cyclic neuromuscular electrical stimulation	Passive Movement Training	Spasticity	−
Passive Movement Training with cyclic neuromuscular electrical stimulation	Cyclic neuromuscular electrical stimulation	Gait speed	+
Passive Movement Training with cyclic neuromuscular electrical stimulation	Cyclic neuromuscular electrical stimulation	Spasticity	−
Cyclic neuromuscular electrical stimulation	Trunk/Core Training	Activities of daily living	−
Cyclic neuromuscular electrical stimulation	Trunk/Core Training	Balance	=
Trunk neuromuscular electrical stimulation with Core muscle training	Trunk neuromuscular electrical stimulation	Activities of daily living, balance	−
Sensory threshold neuromuscular electrical stimulation with Conventional therapy	Conventional therapy	Spasticity, range of motion	+
Sensory threshold neuromuscular electrical stimulation with Conventional therapy	Conventional therapy	Functional mobility	−
Contralaterally controlled neuromuscular electrical stimulation with conventional therapy	neuromuscular electrical stimulation with conventional therapy	Motor recovery, activities of daily living	+
Contralaterally controlled neuromuscular electrical stimulation with conventional therapy	neuromuscular electrical stimulation with conventional therapy	Neurophysiological measures	−

Contralaterally Controlled neuromuscular electrical stimulation	Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation	Range of motion, neurophysiological measures, activities of daily living, gait speed, functional mobility, biomechanical gait measures, muscle strength	–
Contralaterally Controlled neuromuscular electrical stimulation	Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation	Motor recovery	=
Contralaterally Controlled neuromuscular electrical stimulation	Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation	Biomechanical gait measures, muscle strength, range of motion, gait speed, functional mobility	–
Mirror Therapy with Cyclic neuromuscular electrical stimulation	Conventional Therapy	Muscle strength, gait speed, balance	+
Mirror Therapy with Cyclic neuromuscular electrical stimulation	Conventional Therapy	Motor recovery, spasticity, range of motion, gait endurance, functional mobility	–
Neuromuscular electrical stimulation Therapy	Mirror Therapy	Motor recovery, activities of daily living, balance	–
Neuromuscular electrical stimulation with Exercise Therapy	Exercise Therapy	Motor recovery, gait speed, gait endurance, functional mobility, balance, quality of life	–
Neuromuscular electrical stimulation with Walking Training	Conventional Walking Training with Ankle-Foot Orthosis	Gait speed	+
Neuromuscular electrical stimulation with Walking Training	Conventional Walking Training with Ankle-Foot Orthosis	Motor recovery, muscle strength, spasticity, activities of daily living	–
Neuromuscular electrical stimulation with Walking Training	Conventional Walking Training with Ankle-Foot Orthosis	Functional mobility	=
Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles	Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles	Muscle strength, spasticity, range of motion, gait speed, gait endurance	–
Neuromuscular electrical stimulation with Passive Ankle Movement Training	neuromuscular electrical stimulation Alone	Motor recovery, biomechanical gait measures, muscle strength, range of motion, sensory and proprioceptive function, gait speed, functional mobility, balance, falls and fear of falling	–
Neuromuscular electrical stimulation Stimulation	Sham Stimulation	Spasticity	+
Neuromuscular electrical stimulation Stimulation	Sham Stimulation	Gait speed, functional mobility	–
Neuromuscular electrical stimulation (NMES)	Sham NMES	Spasticity, neurophysiological measures, gait speed	–
Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Range of motion	+
Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training,	Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory	Balance	–

acupuncture treatment, occupational therapy)	training, acupuncture treatment, occupational therapy)		
Electromyography-triggered Pedaling training	Pedaling training	Motor recovery, biomechanical gait measures, gait speed	+
Electromyography-triggered Pedaling training	Pedaling training	Neurophysiological measures	=
Proprioceptive neuromuscular facilitation trunk pattern with electromyography-triggered functional electrical stimulation	proprioceptive neuromuscular facilitation trunk pattern	Functional mobility, balance	–
Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy	Electromyography triggered neuromuscular electrical stimulation training (single electrical stimulation) with conventional physiotherapy	Biomechanical balance measures, gait speed	–
Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy	Conventional rehabilitation	Gait speed	+
Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy	Conventional rehabilitation	Biomechanical balance measures	–
Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation	rehabilitation	Activities of daily living, balance	+
Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation	Neuromuscular Electrical Stimulation with Early Rehabilitation	Activities of daily living, balance	–
Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation)	Functional electric stimulation (functional electrical stimulation)	Biomechanical balance measures	+
Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation)	Functional electric stimulation (functional electrical stimulation)	Neurophysiological measures, balance	–
Tele-supervising rehabilitation (physical therapy with electromyography-neuromuscular electrical stimulation)	Conventional Care	Activities of daily living, balance, quality of life	–
Neuromuscular Electrical Stimulation	Occupational Therapy	Neurophysiological measures	+
Neuromuscular Electrical Stimulation	Occupational Therapy	Muscle strength	–
Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy	Conventional therapy	Muscle strength, balance	+
Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy	Conventional therapy	Spasticity, gait endurance, functional mobility	–

Neuromuscular electrical stimulation (Walkaide) with walking training and conventional therapy	Walking training with ankle-foot-orthosis and conventional therapy	Gait speed	+
Neuromuscular electrical stimulation (Walkaide) with walking training and conventional therapy	Walking training with ankle-foot-orthosis and conventional therapy	Motor recovery, muscle strength, spasticity, activities of daily living	–
Neuromuscular electrical stimulation (Walkaide) with walking training and conventional therapy	Walking training with ankle-foot-orthosis and conventional therapy	Functional mobility	=

Transcutaneous Electrical Nerve Stimulation (TENS)

Adopted from: https://nerve-injury.com/transcutaneous-electrical-nerve-stimulation/

Transcutaneous electrical nerve stimulation (TENS) involves the application of electrical current through surface electrodes on the skin to facilitate activation of nerves (Teoli et al., 2024). TENS units are often small, portable, battery-operated devices, and have been used over antagonist muscles to reduce the spasticity of corresponding agonist muscles in stroke rehabilitation practice (Koyama et al., 2016; Teoli et al., 2024).

One possible neural mechanism underlying the reduced spasticity induced by TENS is improved spinal inhibitory reflexes from the stimulated muscle groups or nerve to the reciprocal muscle groups or nerve (Koyama et al., 2016). The application of afferent electrical stimulation at the sensory level may help to enhance neuroplasticity of the brain, through increased activation and recruitment of cortical networks involving contralesional primary sensory cortex, supplementary motor area, dorsal premotor cortex, posterior parietal cortex, and secondary sensory cortices (Sonde et al., 1998; Veldman et al., 2015).

A total of 21 RCTs were found that evaluated transcutaneous electrical nerve stimulation (TENS) for lower extremity motor rehabilitation. Eight RCTs compared TENS Stimulation, Conventional Therapy or No Treatment with Sham Stimulation, Conventional Therapy or No Treatment (Ertzgaard et al. 2018 Mixed population, cerebral palsy; Gurcan et al. 2015; Park et al. 2014a; Cho et al. 2013a; Tyson et al. 2013; Martins et al. 2012; Yan & Hui-Chan 2009; Levin & Hui-Chan 1992). One RCT compared TENS + exercise with Sham TENS + exercise, TENS only, or No Treatment (Tekeoğlu et al. 1998). Five RCTs evaluated TENS + Task-related Training (Laddha et al. 2016; Ng et al. 2016; Chan et al. 2015; Hui-Chan et al. 2009; Ng & Hui-Chan 2007). One RCT compared Unilateral TENS with Bilateral TENS (Kwong et al. 2018). One RCT compared TENS vs Conventional Therapy with NMES vs Conventional Therapy (Yen et al. 2019). One RCT compared TENS Ultrasound vs Botulinum Toxin A with Therapeutic Ultrasound vs Botulinum Toxin A (Picelli et al. 2014). One RCT compared Electroacupuncture and Low Frequency TENS with High and Low Frequency TENS (Johansson et al. 2001). One RCT compared Balance Training + TENS with Sham TENS + Balance Training vs Conventional Care (Jung et al. 2016). One RCT compared Trunk Training with Balance Training and TENS with Treadmill Training and Placebo TENS (Lim et al.

2019). One RCT compared TENS with Heel-raise-lower training with Placebo TENS with Heel-raise-lower training (Jung et al. 2020b).

In addition, seven RCTs in which transcutaneous electrical nerve stimulation (TENS) formed part of a combined or comparative intervention are cross-referenced at the end of Table 30; their primary listings appear in other tables.

The methodological details and results of all 21 RCTs are presented in Table 30.

Table 30. RCTs Evaluating Transcutaneous Electrical Nerve Stimulation (TENS) for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
TENS vs Sham Stimulation, Conventional Therapy or No Treatment		
Ertzgaard et al. (2018) RCT crossover (10) Nstart=29 Nend=27 TPS=Chronic A vs 0 Mixed population (includes cerebral palsy). Ng & Hui-Chan (2007) RCT (6) Nstart=88 Nend=80 TPS=Chronic A vs B vs A + C vs D Primary listing: Table 5 (Task-Specific Training)	E1: TENS E2: Placebo TENS + Task- related training E3: TENS + Task-related training C: No active treatment Duration: 60min/d, 5d/wk for 4wks	E1/E2/E3 vs C: Composite Spasticity scale (+exp1, +exp2, +exp3) Maximum isometric voluntary contradiction peak torque-ankle dorsiflexors (+exp1, +exp2, +exp3) peak torque-ankle plantarflexors (+exp2, +exp3) Gait velocity (+exp3)

		E3 vs E1: Composite Spasticity scale (-) Maximum isometric voluntary contradiction peak torque-ankle dorsiflexors (-) peak torque-ankle plantarflexors (-) Gait velocity (+exp3) E3 vs E2: Composite Spasticity scale (-) Maximum isometric voluntary contradiction peak torque-ankle dorsiflexors (-) peak torque-ankle plantarflexors (-) Gait velocity (+exp3)
Bayram et al. (2006) RCT (5) Nstart=12 Nend=11 TPS=Chronic A + B vs A Primary listing: Table 46 (Botulinum Toxin)	E1: Low-dose Botulinum toxin (100U) + TENS C: High-dose Botulinum toxin (400U) + Sham electrical stimulation Duration: 30min, 6sessions/d, for 3d TENS	E1 vs C: Modified Ashworth Scale (-) AROM-Ankle (-) PROM-Ankle (-) Global Assessment of Spasticity Scale (-) Clonus Score (-) Brace Wear Scale (-) 10-Metre Walk Test (-) Ankle Resting Position Angle (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	There is conflicting evidence about the effect of Transcutaneous electrical nerve stimulation when compared to Sham Stimulation, Conventional Therapy or No Treatment for improving motor recovery.	1	Gurcan et al. 2015
1b	Unilateral transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Bilateral transcutaneous electrical nerve stimulation for improving motor recovery.	1	Kwong et al. 2018

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Transcutaneous electrical nerve stimulation may produce greater improvements in biomechanical gait measures than Sham Stimulation, Conventional Therapy or No Treatment.	1	Park et al. 2014a

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Transcutaneous electrical nerve stimulation may produce greater improvements in biomechanical balance measures than Sham Stimulation, Conventional Therapy or No Treatment.	2	Park et al. 2014a; Cho et al. 2013a
1b	Sit-to-stand training with transcutaneous electrical nerve stimulation and conventional therapy may produce greater improvements in biomechanical balance measures than Sit-to-stand training with sham transcutaneous electrical nerve stimulation and conventional therapy.	1	Jung et al. 2017b

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Transcutaneous electrical nerve stimulation may produce greater improvements in muscle strength than Sham Stimulation, Conventional Therapy or No Treatment.	3	Tyson et al. 2013; Yan & Hui-Chan 2009; Levin & Hui-Chan 1992
2	Transcutaneous electrical nerve stimulation with rehabilitation may not have a difference in efficacy when compared to Sham transcutaneous electrical nerve stimulation with rehabilitation for improving muscle strength.	1	Yan & Hui-Chan 2009
1b	TENS with Task-related training or Sham TENS and Task- related training may produce greater improvements in muscle strength than No active treatment (health education).	1	Chan et al. 2015
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to Sham transcutaneous electrical nerve stimulation with Task- related training for improving muscle strength.	1	Chan et al. 2015
1a	There is conflicting evidence about the effect of TENS with Task-related training when compared to TENS for improving muscle strength.	2	Hui-Chan et al. 2009; Ng & Hui-Chan 2007
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task-related training for improving muscle strength.	1	Hui-Chan et al. 2009
1b	There is conflicting evidence about the effect of Transcutaneous electrical nerve stimulation when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training for improving muscle strength.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training for improving muscle strength.	1	Ng & Hui-Chan 2007
1b	Unilateral transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Bilateral transcutaneous electrical nerve stimulation for improving muscle strength.	1	Kwong et al. 2018
1b	Transcutaneous electrical nerve stimulation with Heel-raise-lower training may produce greater improvements in muscle strength than Placebo transcutaneous electrical nerve stimulation with Heel-raise-lower training.	1	Jung et al. 2020b
1b	Transcutaneous electrical nerve stimulation with Taping and Exercise may produce greater improvements in muscle strength than transcutaneous electrical nerve stimulation with Exercise.	1	In et al. 2021b

1b	Sit-to-stand training with transcutaneous electrical nerve stimulation and conventional therapy may not have a difference in efficacy when compared to Sit-to-stand training with sham transcutaneous electrical nerve stimulation and conventional therapy for improving muscle strength.	1	Jung et al. 2017b

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Transcutaneous electrical nerve stimulation may produce greater improvements in spasticity than Sham Stimulation, Conventional Therapy or No Treatment.	6	Ertzgaard et al. 2018; Gurcan et al. 2015; Park et al. 2014a; Cho et al. 2013a; Yan & Hui-Chan 2009; Levin & Hui-Chan 1992
2	Transcutaneous electrical nerve stimulation with rehabilitation may not have a difference in efficacy when compared to Sham transcutaneous electrical nerve stimulation with rehabilitation for improving spasticity.	1	Yan & Hui-Chan 2009
2	Transcutaneous electrical nerve stimulation with exercise may not have a difference in efficacy when compared to Sham transcutaneous electrical nerve stimulation with exercise, transcutaneous electrical nerve stimulation only, or No Treatment for improving spasticity.	1	Tekeoğlu et al. 1998
2	Transcutaneous electrical nerve stimulation with Task-related Training may produce greater improvements in spasticity than Task-related training.	1	Laddha et al. 2016
2	There is conflicting evidence about the effect of Transcutaneous electrical nerve stimulation (60min) with Task- related training when compared to transcutaneous electrical nerve stimulation (30min) with Task- related training for improving spasticity.	1	Laddha et al. 2016
1a	TENS with Task-related training may not have a difference in efficacy when compared to TENS for improving spasticity.	2	Hui-Chan et al. 2009; Ng & Hui-Chan 2007
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task-related training for improving spasticity.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training for improving spasticity.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training for improving spasticity.	1	Ng & Hui-Chan 2007
1b	Therapeutic ultrasound with Home exercises & conventional therapy may not have a difference in efficacy when compared to transcutaneous electrical nerve stimulation with Home exercises & conventional therapy for improving spasticity.	1	Picelli et al. 2014
1b	Therapeutic ultrasound with Home exercises & conventional therapy may result in lesser improvements in spasticity when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.	1	Picelli et al. 2014
1b	Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy may result in lesser improvements in spasticity when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.	1	Picelli et al. 2014

1b	Transcutaneous electrical nerve stimulation with Heel-raise-lower training may produce greater improvements in spasticity than Placebo transcutaneous electrical nerve stimulation with Heel-raise-lower training.	1	Jung et al. 2020b
1b	Transcutaneous electrical nerve stimulation with Taping and Exercise may produce greater improvements in spasticity than transcutaneous electrical nerve stimulation with Exercise.	1	In et al. 2021b
1b	Sit-to-stand training with transcutaneous electrical nerve stimulation and conventional therapy may produce greater improvements in spasticity than Sit-to-stand training with sham transcutaneous electrical nerve stimulation and conventional therapy.	1	Jung et al. 2017b
2	Low-dose Botulinum toxin (100U) with transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to High-dose Botulinum toxin (400U) with Sham electrical stimulation for improving spasticity.	1	Bayram et al. 2006

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Sham Stimulation, Conventional Therapy or No Treatment for improving range of motion.	2	Ertzgaard et al. 2018; Gurcan et al. 2015
2	Transcutaneous electrical nerve stimulation with Task-related Training may not have a difference in efficacy when compared to Task-related training for improving range of motion.	1	Laddha et al. 2016
2	Transcutaneous electrical nerve stimulation (60min) with Task-related training may produce greater improvements in range of motion than transcutaneous electrical nerve stimulation (30min) with Task- related training.	1	Laddha et al. 2016
1b	Therapeutic ultrasound with Home exercises & conventional therapy may not have a difference in efficacy when compared to transcutaneous electrical nerve stimulation with Home exercises & conventional therapy for improving range of motion.	1	Picelli et al. 2014
1b	Therapeutic ultrasound with Home exercises & conventional therapy may result in lesser improvements in range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.	1	Picelli et al. 2014
1b	Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy may result in lesser improvements in range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.	1	Picelli et al. 2014
2	Low-dose Botulinum toxin (100U) with transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to High-dose Botulinum toxin (400U) with Sham electrical stimulation for improving range of motion.	1	Bayram et al. 2006

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Transcutaneous electrical nerve stimulation may produce greater improvements in neurophysiological measures than Sham Stimulation, Conventional Therapy or No Treatment.	2	Martins et al. 2012; Levin & Hui-Chan 1992
2	Transcutaneous electrical nerve stimulation may produce greater improvements in neurophysiological measures than Cryotherapy.	1	Martins et al. 2012

1b	Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care may produce greater improvements in neurophysiological measures than Conventional care.	1	Jung et al. 2016
1b	Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care may produce greater improvements in neurophysiological measures than Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care.	1	Jung et al. 2016
1b	Balance Training with transcutaneous electrical nerve stimulation may produce greater improvements in neurophysiological measures than Sham transcutaneous electrical nerve stimulation with Balance Training or Conventional Care.	1	Jung et al. 2016

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Transcutaneous electrical nerve stimulation when compared to Sham Stimulation, Conventional Therapy or No Treatment for improving sensory and proprioceptive function.	1	Tyson et al. 2013
1b	Trunk Training with Balance Training and transcutaneous electrical nerve stimulation may produce greater improvements in sensory and proprioceptive function than Treadmill Training and Placebo transcutaneous electrical nerve stimulation.	1	Lim et al. 2019
1b	Instructed sensory training with transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Uninstructed sensory training with transcutaneous electrical nerve stimulation for improving sensory and proprioceptive function.	1	Ofek et al. 2023
1b	Multi-sensorimotor training (Stabilize-T and Reha bar exercises with transcutaneous electrical nerve stimulation) and Conventional physical therapy may produce greater improvements in sensory and proprioceptive function than Treadmill training with placedo transcutaneous electrical nerve stimulation and conventional physical therapy.	1	Lim et al. 2019

PAIN			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Sham Stimulation, Conventional Therapy or No Treatment for improving pain.	1	Ertzgaard et al. 2018

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Sham Stimulation, Conventional Therapy or No Treatment for improving activities of daily living.	2	Ertzgaard et al. 2018; Gurcan et al. 2015
2	Transcutaneous electrical nerve stimulation with exercise may not have a difference in efficacy when compared to Sham transcutaneous electrical nerve stimulation with exercise, transcutaneous electrical nerve stimulation only, or No Treatment for improving activities of daily living.	1	Tekeoğlu et al. 1998

1b	Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation may produce greater improvements in activities of daily living than Neuromuscular Electrical Stimulation with Early Rehabilitation.	1	Yen et al. 2019
1b	Transcutaneous electrical nerve stimulation vs Conventional Therapy may not have a difference in efficacy when compared to neuromuscular electrical stimulation or Conventional Therapy for improving activities of daily living.	1	Yen et al. 2019
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high-frequency transcutaneous electrical nerve stimulation (2Hz) electrostimulation for improving activities of daily living.	1	Johansson et al. 2001

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Transcutaneous electrical nerve stimulation when compared to Sham Stimulation, Conventional Therapy or No Treatment for improving gait speed.	3	Ertzgaard et al. 2018; Gurcan et al. 2015; Park et al. 2014a
1b	Transcutaneous electrical nerve stimulation may produce greater improvements in gait speed than No treatment.	1	Hui-Chan et al. 2009
1a	TENS with Task-related training may produce greater improvements in gait speed than TENS.	2	Hui-Chan et al. 2009; Ng & Hui-Chan 2007
1b	Transcutaneous electrical nerve stimulation with Task-related training may produce greater improvements in gait speed than Placebo transcutaneous electrical nerve stimulation with Task-related training.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training for improving gait speed.	1	Hui-Chan et al. 2009
1b	TENS with Task-related training may produce greater improvements in gait speed than No treatment.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation may produce greater improvements in gait speed than No active treatment.	1	Ng & Hui-Chan 2007
1b	Transcutaneous electrical nerve stimulation with Task-related training may produce greater improvements in gait speed than transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training.	1	Ng & Hui-Chan 2007
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high-frequency transcutaneous electrical nerve stimulation (2Hz) electrostimulation for improving gait speed.	1	Johansson et al. 2001
1b	Transcutaneous electrical nerve stimulation with Heel-raise-lower training may produce greater improvements in gait speed than Placebo transcutaneous electrical nerve stimulation with Heel-raise-lower training.	1	Jung et al. 2020b
1b	Transcutaneous electrical nerve stimulation with Taping and Exercise may produce greater improvements in gait speed than transcutaneous electrical nerve stimulation with Exercise.	1	In et al. 2021b
2	Low-dose Botulinum toxin (100U) with transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to High-dose Botulinum toxin (400U) with Sham electrical stimulation for improving gait speed.	1	Bayram et al. 2006

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy may not have a difference in efficacy when compared to C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy for improving gait endurance.	1	Ng et al. 2016
1b	TENS with Task-related training may produce greater improvements in gait endurance than TENS.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation with Task-related training may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task-related training for improving gait endurance.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training for improving gait endurance.	1	Hui-Chan et al. 2009

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Sham Stimulation, Conventional Therapy or No Treatment for improving functional mobility.	4	Ertzgaard et al. 2018; Gurcan et al. 2015; Park et al. 2014a; Yan & Hui-Chan 2009
2	Transcutaneous electrical nerve stimulation with rehabilitation may not have a difference in efficacy when compared to Sham transcutaneous electrical nerve stimulation with rehabilitation for improving functional mobility.	1	Yan & Hui-Chan 2009
2	Transcutaneous electrical nerve stimulation with Task-related Training may not have a difference in efficacy when compared to Task-related training for improving functional mobility.	1	Laddha et al. 2016
1b	There is conflicting evidence about the effect of Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy when compared to C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy for improving functional mobility.	1	Ng et al. 2016
1b	TENS with Task-related training may produce greater improvements in functional mobility than TENS.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation with Task-related training may produce greater improvements in functional mobility than Placebo transcutaneous electrical nerve stimulation with Task-related training.	1	Hui-Chan et al. 2009
1b	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training for improving functional mobility.	1	Hui-Chan et al. 2009
1b	There is conflicting evidence about the effect of Unilateral transcutaneous electrical nerve stimulation when compared to Bilateral transcutaneous electrical nerve stimulation for improving functional mobility.	1	Kwong et al. 2018
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high-frequency transcutaneous electrical nerve stimulation (2Hz) electrostimulation for improving functional mobility.	1	Johansson et al. 2001

1b	Instructed sensory training with transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Uninstructed sensory training with transcutaneous electrical nerve stimulation for improving functional mobility.	1	Ofek et al. 2023

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy may produce greater improvements in balance than C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy.	1	Ng et al. 2016
1b	TENS with Task-related training or Sham TENS and Task- related training may produce greater improvements in balance than No active treatment (health education).	1	Chan et al. 2015
1b	Transcutaneous electrical nerve stimulation with Task-related training may produce greater improvements in balance than Sham transcutaneous electrical nerve stimulation with Task- related training.	1	Chan et al. 2015

Other Associated Outcome Measures

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Sham Stimulation, Conventional Therapy or No Treatment for improving upper extremity function.	1	Ertzgaard et al. 2018

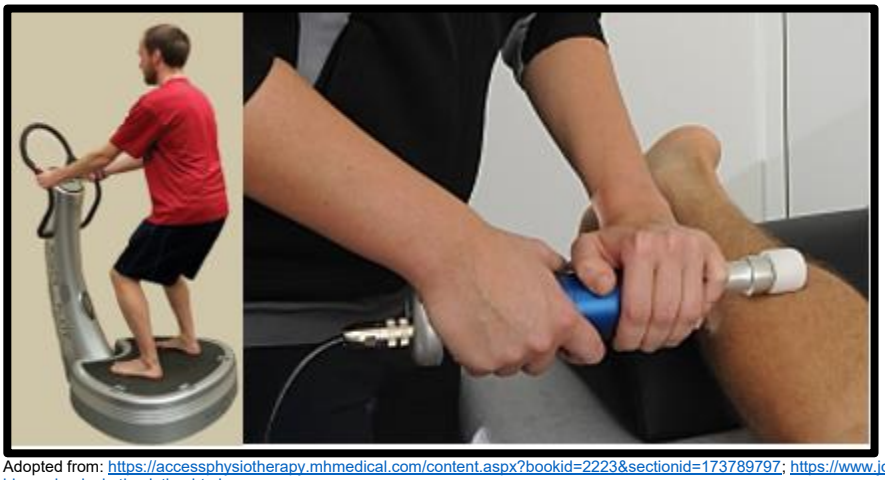
Key Points

- Transcutaneous electrical nerve stimulation may be beneficial for improving biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, and neurophysiological measures, but not range of motion, pain, activities of daily living, functional mobility, and quality of life, after stroke when compared to Sham Stimulation, Conventional Therapy or No Treatment; the literature is mixed regarding motor recovery, sensory and proprioceptive function, and gait speed.
- Transcutaneous electrical nerve stimulation may be beneficial for improving neurophysiological measures after stroke when compared to Cryotherapy.
- Transcutaneous electrical nerve stimulation with rehabilitation may not be beneficial for improving muscle strength, spasticity, and functional mobility after stroke when compared to Sham transcutaneous electrical nerve stimulation with rehabilitation.
- Transcutaneous electrical nerve stimulation with exercise may not be beneficial for improving spasticity and activities of daily living after stroke when compared to Sham transcutaneous electrical nerve stimulation with exercise, transcutaneous electrical nerve stimulation only, or No Treatment.

- Transcutaneous electrical nerve stimulation with Task-related Training may be beneficial for improving spasticity, but not range of motion and functional mobility, after stroke when compared to Task-related training.
- Transcutaneous electrical nerve stimulation (60min) with Task- related training may be beneficial for improving range of motion after stroke when compared to transcutaneous electrical nerve stimulation (30min) with Task- related training; the literature is mixed regarding spasticity.
- Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy may be beneficial for improving balance, but not gait endurance and quality of life, after stroke when compared to C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy; the literature is mixed regarding functional mobility.
- TENS with Task-related training or Sham TENS and Task- related training may be beneficial for improving muscle strength and balance after stroke when compared to No active treatment (health education).
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving balance, but not muscle strength, after stroke when compared to Sham transcutaneous electrical nerve stimulation with Task- related training.
- Transcutaneous electrical nerve stimulation may be beneficial for improving gait speed after stroke when compared to No treatment.
- TENS with Task-related training may be beneficial for improving gait speed, gait endurance, and functional mobility, but not spasticity, after stroke when compared to TENS; the literature is mixed regarding muscle strength.
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving gait speed and functional mobility, but not muscle strength, spasticity, and gait endurance, after stroke when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training.
- Transcutaneous electrical nerve stimulation may not be beneficial for improving spasticity, gait speed, gait endurance, and functional mobility after stroke when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training; the literature is mixed regarding muscle strength.
- Transcutaneous electrical nerve stimulation may be beneficial for improving gait speed after stroke when compared to No active treatment.
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving gait speed, but not muscle strength and spasticity, after stroke when compared to transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training.
- Unilateral transcutaneous electrical nerve stimulation may not be beneficial for improving motor recovery, muscle strength, and balance after stroke when compared to Bilateral transcutaneous electrical nerve stimulation; the literature is mixed regarding functional mobility.
- Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation may be beneficial for improving activities of daily living and balance after stroke when compared to Neuromuscular Electrical Stimulation with Early Rehabilitation.
- Transcutaneous electrical nerve stimulation vs Conventional Therapy may not be beneficial for improving activities of daily living and balance after stroke when compared to neuromuscular electrical stimulation or Conventional Therapy.
- Therapeutic ultrasound with Home exercises & conventional therapy may not be beneficial for improving spasticity and range of motion after stroke when compared to transcutaneous electrical nerve stimulation with Home exercises & conventional therapy.
- Therapeutic ultrasound with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Electroacupuncture may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Low-intensity, high-frequency transcutaneous electrical nerve stimulation (2Hz) electrostimulation.

- Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care may be beneficial for improving neurophysiological measures and balance after stroke when compared to Conventional care.
- Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care may be beneficial for improving neurophysiological measures and balance after stroke when compared to Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care.
- Balance Training with transcutaneous electrical nerve stimulation may be beneficial for improving neurophysiological measures after stroke when compared to Sham transcutaneous electrical nerve stimulation with Balance Training or Conventional Care; the literature is mixed regarding balance.
- Trunk Training with Balance Training and transcutaneous electrical nerve stimulation may be beneficial for improving sensory and proprioceptive function, but not balance, after stroke when compared to Treadmill Training and Placebo transcutaneous electrical nerve stimulation.
- Transcutaneous electrical nerve stimulation with Heel-raise-lower training may be beneficial for improving muscle strength, spasticity, and gait speed after stroke when compared to Placebo transcutaneous electrical nerve stimulation with Heel-raise-lower training.
- Instructed sensory training with transcutaneous electrical nerve stimulation may not be beneficial for improving sensory and proprioceptive function, functional mobility, falls and fear of falling, and quality of life after stroke when compared to Uninstructed sensory training with transcutaneous electrical nerve stimulation.
- Transcutaneous electrical nerve stimulation with Taping and Exercise may be beneficial for improving muscle strength, spasticity, and gait speed after stroke when compared to transcutaneous electrical nerve stimulation with Exercise.
- Multi-sensorimotor training (Stabilize-T and Reha bar exercises with transcutaneous electrical nerve stimulation) and Conventional physical therapy may be beneficial for improving sensory and proprioceptive function, but not balance, after stroke when compared to Treadmill training with placedo transcutaneous electrical nerve stimulation and conventional physical therapy.
- Sit-to-stand training with transcutaneous electrical nerve stimulation and conventional therapy may be beneficial for improving biomechanical balance measures and spasticity, but not muscle strength, after stroke when compared to Sit-to-stand training with sham transcutaneous electrical nerve stimulation and conventional therapy.
- Low-dose Botulinum toxin (100U) with transcutaneous electrical nerve stimulation may not be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to High-dose Botulinum toxin (400U) with Sham electrical stimulation.
- TENS with Task-related training may be beneficial for improving gait speed after stroke when compared to No treatment.

Summary of Key Points: Transcutaneous Electrical Nerve Stimulation (TENS)



Intervention	Control(s)	Function domain(s)	Effect
Transcutaneous electrical nerve stimulation Stimulation, Conventional Therapy or No Treatment	Sham Stimulation, Conventional Therapy or No Treatment	Biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, neurophysiological measures	+
Transcutaneous electrical nerve stimulation Stimulation, Conventional Therapy or No Treatment	Sham Stimulation, Conventional Therapy or No Treatment	Range of motion, pain, activities of daily living, functional mobility, quality of life	–
Transcutaneous electrical nerve stimulation Stimulation, Conventional Therapy or No Treatment	Sham Stimulation, Conventional Therapy or No Treatment	Motor recovery, sensory and proprioceptive function, gait speed	=
Transcutaneous electrical nerve stimulation	Cryotherapy	Neurophysiological measures	+
Transcutaneous electrical nerve stimulation with rehabilitation	Sham transcutaneous electrical nerve stimulation with rehabilitation	Muscle strength, spasticity, functional mobility	–

Transcutaneous electrical nerve stimulation with exercise	Sham transcutaneous electrical nerve stimulation with exercise, transcutaneous electrical nerve stimulation only, or No Treatment	Spasticity, activities of daily living	–
Transcutaneous electrical nerve stimulation with Task-related Training	Task-related training	Spasticity	+
Transcutaneous electrical nerve stimulation with Task-related Training	Task-related training	Range of motion, functional mobility	–
Transcutaneous electrical nerve stimulation (60min) with Task- related training	transcutaneous electrical nerve stimulation (30min) with Task-related training	Range of motion	+
Transcutaneous electrical nerve stimulation (60min) with Task- related training	transcutaneous electrical nerve stimulation (30min) with Task-related training	Spasticity	=
Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy	Balance	+
Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy	Gait endurance, quality of life	–
Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy	Functional mobility	=
TENS with Task-related training or Sham TENS and Task- related training	No active treatment (health education)	Muscle strength, balance	+
Transcutaneous electrical nerve stimulation with Task-related training	Sham transcutaneous electrical nerve stimulation with Task-related training	Balance	+
Transcutaneous electrical nerve stimulation with Task-related training	Sham transcutaneous electrical nerve stimulation with Task-related training	Muscle strength	–
Transcutaneous electrical nerve stimulation	No treatment	Gait speed	+
TENS with Task-related training	TENS	Gait speed, gait endurance, functional mobility	+
TENS with Task-related training	TENS	Spasticity	–
Transcutaneous electrical nerve stimulation with Task-related training	Placebo transcutaneous electrical nerve stimulation with Task-related training	Gait speed, functional mobility	+
Transcutaneous electrical nerve stimulation with Task-related training	Placebo transcutaneous electrical nerve stimulation with Task-related training	Muscle strength, spasticity, gait endurance	–
Transcutaneous electrical nerve stimulation	Placebo transcutaneous electrical nerve stimulation with Task-related training	Spasticity, gait speed, gait endurance, functional mobility	–
Transcutaneous electrical nerve stimulation	Placebo transcutaneous electrical nerve stimulation with Task-related training	Muscle strength	=

Transcutaneous electrical nerve stimulation	No active treatment	Gait speed	+
TENS with Task-related training	TENS	Gait speed	+
Transcutaneous electrical nerve stimulation with Task-related training	transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training	Gait speed	+
Transcutaneous electrical nerve stimulation with Task-related training	transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training	Muscle strength, spasticity	–
Unilateral transcutaneous electrical nerve stimulation	Bilateral transcutaneous electrical nerve stimulation	Motor recovery, muscle strength, balance	–
Unilateral transcutaneous electrical nerve stimulation	Bilateral transcutaneous electrical nerve stimulation	Functional mobility	=
Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation	Neuromuscular Electrical Stimulation with Early Rehabilitation	Activities of daily living, balance	+
Transcutaneous electrical nerve stimulation vs Conventional Therapy	neuromuscular electrical stimulation vs Conventional Therapy	Activities of daily living, balance	–
Therapeutic ultrasound with Home exercises & conventional therapy	transcutaneous electrical nerve stimulation with Home exercises & conventional therapy	Spasticity, range of motion	–
Therapeutic ultrasound with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy	Spasticity, range of motion	–
Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy	Spasticity, range of motion	–
Electroacupuncture	Low-intensity, high-frequency transcutaneous electrical nerve stimulation (2Hz) electrostimulation	Activities of daily living, gait speed, functional mobility, quality of life	–
Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care	Conventional care	Neurophysiological measures, balance	+
Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care	Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care	Neurophysiological measures, balance	+
Balance Training with transcutaneous electrical nerve stimulation	Sham transcutaneous electrical nerve stimulation with Balance Training vs Conventional Care	Neurophysiological measures	+
Balance Training with transcutaneous electrical nerve stimulation	Sham transcutaneous electrical nerve stimulation with Balance Training vs Conventional Care	Balance	=
Trunk Training with Balance Training and transcutaneous electrical nerve stimulation	Treadmill Training and Placebo transcutaneous electrical nerve stimulation	Sensory and proprioceptive function	+

Trunk Training with Balance Training and transcutaneous electrical nerve stimulation	Treadmill Training and Placebo transcutaneous electrical nerve stimulation	Balance	−
Transcutaneous electrical nerve stimulation with Heel-raise-lower training	Placebo transcutaneous electrical nerve stimulation with Heel-raise-lower training	Muscle strength, spasticity, gait speed	+
Instructed sensory training with transcutaneous electrical nerve stimulation	Uninstructed sensory training with transcutaneous electrical nerve stimulation	Sensory and proprioceptive function, functional mobility, falls and fear of falling, quality of life	−
Transcutaneous electrical nerve stimulation with Taping and Exercise	transcutaneous electrical nerve stimulation with Exercise	Muscle strength, spasticity, gait speed	+
Multi-sensorimotor training (Stabilize-T and Reha bar exercises with transcutaneous electrical nerve stimulation) and Conventional physical therapy	Treadmill training with placedo transcutaneous electrical nerve stimulation and conventional physical therapy	Sensory and proprioceptive function	+
Multi-sensorimotor training (Stabilize-T and Reha bar exercises with transcutaneous electrical nerve stimulation) and Conventional physical therapy	Treadmill training with placedo transcutaneous electrical nerve stimulation and conventional physical therapy	Balance	−
Sit-to-stand training with transcutaneous electrical nerve stimulation and conventional therapy	Sit-to-stand training with sham transcutaneous electrical nerve stimulation and conventional therapy	Biomechanical balance measures, spasticity	+
Sit-to-stand training with transcutaneous electrical nerve stimulation and conventional therapy	Sit-to-stand training with sham transcutaneous electrical nerve stimulation and conventional therapy	Muscle strength	−
Low-dose Botulinum toxin (100U) with transcutaneous electrical nerve stimulation	High-dose Botulinum toxin (400U) with Sham electrical stimulation	Spasticity, range of motion, gait speed	−
TENS with Task-related training	No treatment	Gait speed	+
Transcutaneous electrical nerve stimulation	Sham Stimulation, Conventional Therapy or No Treatment	Motor recovery, sensory and proprioceptive function, gait speed	=
Transcutaneous electrical nerve stimulation	Sham Stimulation, Conventional Therapy or No Treatment	Biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, neurophysiological measures	+
Transcutaneous electrical nerve stimulation	Sham Stimulation, Conventional Therapy or No Treatment	Range of motion, pain, activities of daily living, functional mobility, quality of life	−
TENS with Task-related training	TENS	Muscle strength	=

Muscle Vibration

Adopted from: https://accessphysiotherapy.mhmedical.com/content.aspx?bookid=2223&sectionid=173789797; https://www.joint-surgeon.com/rehabilitation/matrix-therapy/matrix-therapy-and-biomechanical-stimulation.html

Whole body muscle vibration is administered through a vibrating platform which stimulates sensory receptors and can facilitate muscle contractions (Brogårdh et al. 2012). The patient may stand or perform other movements while on the vibration platform. Whole body muscle vibration is being investigated as a therapeutic method of improving muscle function, muscle strength, and gait function following a stroke (Cochrane, 2011; Lee, 2015a).

Muscle vibration produces an indirect vibration to the whole body which can limit the specificity and strength of the vibratory stimulus (Moran et al., 2007). As such, local muscle vibration has recently been examined as a more specific and direct method of applying a vibration stimulation to targeted muscles with the ability to stimulate either the agonist or antagonist muscles, as opposed to stimulating both as would occur during muscle vibration (Custer et al., 2017; Pamukoff et al., 2014; Souron et al., 2017; Tankisheva et al. 2014).

A total of 36 RCTs were found that evaluated muscle vibration for lower extremity motor rehabilitation. 21 RCTs compared Whole Body Vibration with Sham Stimulation, No Stimulation, or Conventional Care (Xu et al. 2024; Duray et al. 2023; Ahmed Burq et al. 2021; Burq et al. 2021b; Sales et al. 2020; Sade et al. 2020; Lee 2019e; Alp et al. 2018; Lee et al. 2017c; Silva et al. 2016; Guo et al. 2015; Lee 2015e; Silva et al. 2014; Tankisheva et al. 2014; Marin et al. 2013; Pang et al. 2013; Chan et al. 2012; Brogårdh et al. 2012; Lau et al. 2012; Tihanyi et al. 2010; Tihanyi et al. 2007). One RCT compared Matrix Rhythm Therapy with Bobath Therapy (Unal et al. 2021). One RCT compared Whole Body Vibration with Musical Exercise Therapy (Van Nes et al. 2006). One RCT compared Balance Training + Whole Body Vibration with Conventional Rehabilitation (Merkert et al. 2011). One RCT compared Whole Body Vibration + Treadmill Training with Treadmill Training (Choi et al. 2017b). Six RCTs compared Local Muscle Vibration with Conventional Therapy or Sham Muscle Vibration (Chen et al. 2023a; Onal et al. 2022; Toscano et al. 2019; Lee et al. 2013a; Paoloni et al. 2010; Magnusson et al. 1994). Three RCTs evaluated Comparing Whole-Body Vibration Intensity (Wei et al. 2022; Yang et al. 2021; Liao et al. 2016). One RCT compared Whole Body Vibration with Strength Training (Irshad et al. 2022).

In addition, four RCTs in which muscle vibration formed part of a combined or comparative intervention are cross-referenced at the end of Table 31; their primary listings appear in other tables.

The methodological details and results of all 36 RCTs are presented in Table 31.

Table 31. RCTs Evaluating Muscle Vibration for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Whole Body Vibration vs Sham Stimulation, No Stimulation, or Conventional Care		
Xu et al. (2024) RCT (8)	E: Whole-body vibration + conventional rehab (physiotherapy, neuromuscular	E vs C: BBS(-)

Nstart=35 Nend=35 TPS=Chronic A vs 0 Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning); Table 29 (Neuromuscular Electrical Stimulation (NMES)); Table 53 (Acupuncture and Massage)	electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) C: Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) Duration: E: 230min/d, 6d/wk, 4wks; C: 200min/d, 6d/wk, 4 wks	Functional Reach Test (-) Romberg's test of balance length (-) area(-) Ankle joint dorsiflexion-plantar flexion (DP)(+exp) Ankle joint inversion-eversion (+exp)
Duray et al. (2023) RCT (5) Nstart=34 Nend=28 TPS=Chronic A + B vs B Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)	E: Whole body vibration + Neurodevelopmental treatment C: Neurodevelopmental treatment Duration: 60min NDT/d, 3d/wk, 4wks; 20min WBV/d, 2d/wk, same 4 wks	E vs C: 6MWT (+exp) Walking Distance (+exp) VO2max (+exp) FEV (-) FVC (-) PEF (-) ERV (-) IC (-) VC (-) IRV (-) chest circumference measurements epigastric (-) subcostal (-) axillar (-)
Ahmed Burq et al. (2021) RCT (5) Nstart=64 Nend=64 TPS=Chronic A vs 0	E: Whole-Body Vibration (amplitude: 3 mm, frequency: 20 Hz) + Routine Physiotherapy C: Routine physiotherapy Duration: 15min, 6d/wk, for 2wks vibration & 45min/session, for 2wks physiotherapy	E vs C: Stair Negotiation Time (+exp) Obstacle Clearance Height (+exp) Obstacle Clearance Depth (-)
Burq et al. (2021b) RCT (6) Nstart=64 Nend=64 TPS=Chronic A vs 0	E: Whole body vibration (WBV, 20Hz) + Conventional therapy C: Conventional therapy Duration: 15min, 6d/wk, for 2wks WBV	E vs C: Timed up and go (-) 10-meter walk test Self-speed (-) Fast speed (-)
Sales et al. (2020) RCT (8) Nstart=21 Nend=21 TPS=Chronic A vs 0	E: Whole-body vibration C: Sham Duration: 10min/1session	E vs C: Hmax/Mmax ratio (-) Modified Ashworth Scale (-) Global perception of change (-)
Sade et al. (2020) RCT (5) Nstart=46 Nend=43 TPS=Chronic A vs B + C vs 0 vs C	E: Whole body vibration (35- 40Hz) + Conventional therapy C: Conventional therapy Duration: E: 4min/session, 5d/wk, for 3wks vibration + 5d/wk, for 3wks conventional therapy C: 5d/wk, for 3wks conventional therapy	E vs C: Berg Balance Scale (+exp) Timed Up and Go Test (+exp) Cadence (-) Single support (-) Double support (-) Step length (+exp) Step time (-)

		Walking speed (+exp)
Lee (2019e) RCT (6) Nstart=24 Nend=21 TPS=Chronic A vs 0	E: Horizontal whole-body vibration + Conventional rehabilitation training C: Conventional rehabilitation training Duration: 30min/d, 3d/wk, for 6wks Whole-body vibration, 60min/d, 3d/wk, for 6wks Conventional rehabilitation	E vs C: Gait Velocity (-) Cadence (-) Step Length (-) Single Limb Support Time (-) Double Limb Support Time (-) Stride Length (-) Movement of the Centre of Pressure (-)
Alp et al. (2018) RCT (6) Nstart=22 Nend=21 TPS=Chronic A vs 0 Also in Table 12 (Stretching or Mobilization Exercises)	E: Whole Body Vibration (40 hz,4 mm) + Exercise (Stretching and active ROM exercise) C: Sham Vibration + Exercise (Stretching and active ROM exercise) Duration: 15min, 3d/wk, for 4wks Exercise & 5min, 3d/wk, for 4wks WBV/Sham	E vs C: 10-meter Walk Test (+exp) Functional Independence Measurement (-) Modified Ashworth Scale-Ankle (-)
Lee et al. (2017c) RCT (7) Nstart=30 Nend=30 TPS=Acute A vs 0	E: Whole Body Vibration + Conventional Therapy C: Conventional Therapy Duration: 60min/d, 5d/wk, for 2wks	E vs C: Functional Ambulation Categories (-) Berg Balance Scale (-) Trunk Impairment Scale (-) Korean Modified Barthel Index (-)
Silva et al. (2016) RCT (6) Nstart=35 Nend=28 TPS=Subacute A vs B	E: Whole-body vibration training C: No stimulation Duration: 4-8min/d, 3d/wk for 8wks	E vs C: Plantar impression area Affected side (-) Unaffected side (-) 6-Minute Walk Test (-)
Guo et al. (2015) RCT (6) Nstart=30 Nend=30 TPS=Subacute A vs 0	E: Whole-body vibration C: Sham stimulation Duration: 80min/d for 8wks	E vs C: 10-Metre Walk Test (+exp) Knee hyperextension (+exp) Fugl-Meyer Assessment (-)
Lee (2015e) RCT (4) Nstart=26 Nend=21 TPS=Chronic A vs B	E: Whole-body vibration in the horizontal direction + Conventional rehabilitation C: No stimulation + Conventional rehabilitation Duration: 15min/d, 3d/wk for 6wks whole body vibration & 30min/d, 5d/wk, for 6wks conventional rehabilitation	E vs C: Berg Balance Scale (+exp) Timed Up-and-Go Test (-) Fugl-Meyer Assessment (-)
Silva et al. (2014) RCT (5) Nstart=43 Nend=38 TPS=Chronic A vs 0	E: Whole body vibration therapy while standing with knees flexed C: Sham Duration: 9min/session - whole body vibration,10min/session - flexed knee position	E vs C: Fugl-Meyer assessment (-) Surface EMG (-) Voluntary Isometric contraction (-) Stair Climb test (-) 6min Walk test (-) Timed Up and Go (-)
Tankisheva et al. (2014) RCT (7) Nstart=15	E: Whole body vibration during exercise C: No intervention	E vs C: Ashworth Scale (-) Muscle strength:

Nend=13 TPS=Chronic A vs B	Duration: 10-19min/d, 3d/wk, for 6wks vibration	Isometric knee extension 60° Paretic leg (+exp) Non-paretic leg (-) Isometric knee flexion 60° Paretic leg (-) Non-paretic leg (-) Isokinetic knee extension 240°/s Paretic leg (-) Non-paretic leg (-) Isokinetic knee flexion 240°/s Paretic leg (+exp) Non-paretic leg (-) Isokinetic knee extension 60°/s Paretic leg (-) Non-paretic leg (-) Isokinetic knee flexion 60°/s Paretic leg (-) Non-paretic leg (-) Sensory Organization Test C1 (-) C2 (-) C3 (-) C4 (+exp) C5 (-) C6 (-)
Marin et al. (2013) RCT (8) Nstart=20 Nend=20 TPS=Chronic A vs 0	E: Whole-body vibration C: Sham stimulation Duration: 1-2d/wk, 12wks (17 total sessions) ; 120min/session, 10 sessions/1mo, for 3mo rehabilitation sessions	E vs C: Berg Balance Scale (-) Lower limb muscle architecture (-) Isometric knee extension (-)
Pang et al. (2013) RCT (8) Nstart=82 Nend=76 TPS=Chronic A vs 0	E: Exercise training + vertical Whole Body Vibration stimulation C: Exercise training + sham WBV Duration: 15min/d, 3d/wk, for 8wks	E vs C: Chedoke McMaster Assessment paretic leg (-) paretic foot (-) Bone turn over marker levels (CTx and BAP) (-) Modified Ashworth Scale knee (-) ankle (-) Knee peak power-both sides (-)
Chan et al. (2012) RCT (8) Nstart=32 Nend=30 TPS=Chronic A vs 0	E: Whole body vibration + regular exercise C: Sham Vibration + regular exercise Duration: single session, 30min	E vs C: Hoffman reflex unaffected side (-) affected side (-) Maximum Hoffman reflex/Maximum M response ratio unaffected side (+exp) affected side (-) Modified Ashworth Scale (+exp) Visual Analog Scale – ankle spasticity (+exp) Achilles Deep Tendon Reflex (-)

		Timed up and Go (+exp) 10-metre walk test (+exp) Cadence (-) Total body weight affected (+exp) unaffected (+exp)
Brogårdh et al. (2012) RCT (9) Nstart=31 Nend=31 TPS=Chronic A vs 0	E: Whole Body Vibration (3.75mm amplitude) C: Sham Vibration (0.2mm Amplitude) Duration: 12 x (40 – 60s) vibration/session, 2 sessions/wk for 6wk	E vs C: Stroke Impact Scale (-) Modified Ashworth Scale (-) Berg Balance Scale (-) Timed UP-and-Go (-) 6-minute walk test (-) Knee Muscle Strength isometric extension (-) isokinetic flexion (-) isokinetic extension (-) 10-meters walk test comfortable speed (-) fast speed (-)
Lau et al. (2012) RCT (8) Nstart=82 Nend=76 TPS=Chronic A + B vs B	E: Whole body vibration + dynamic leg exercises C: Dynamic leg exercises Duration: 9-15min/d, 3d/wk, for 8wks	E vs C: Berg Balance scale (-) Dynamic Postural Control (-) 6-minute walk test (-) 10-meter walk test (-) Isometric muscle strength (peak torque value) (-) Activities-specific balance confidence (-) Fall-related self-efficacy (-)
Tihanyi et al. (2010) RCT (4) Nstart=20 Nend=20 TPS=Acute A vs 0	E: Whole Body Vibration (20Hz) + Conventional Care C: Conventional Care Duration: 3x/wk, for 4wks	E vs C: Maximum isometric torque paretic (+exp) Maximum isometric torque non-paretic (+exp) Rate of torque development paretic (-) Rate of torque development non-paretic (-) Maximum eccentric torque paretic (+exp) Maximum eccentric torque non-paretic (+exp) Mechanical work during eccentric contraction paretic (-) Mechanical work during eccentric contraction non-paretic (-) Maximum isometric torque of vastus lateralis muscle during isometric in paretic (+exp) Maximum isometric torque of vastus lateralis muscle during isometric in non-paretic (-) Maximum eccentric torque of vastus lateralis muscle during isometric in paretic (+exp) Maximum eccentric torque of vastus lateralis muscle during isometric in non-paretic (-) Myoelectrical activity (EMG) (+exp)

Tihanyi et al. (2007) RCT (6) Nstart=18 Nend=16 TPS=Acute A vs 0	E: Whole-body vibration C: Sham Duration: ~18min/ single session	E vs C: Maximum Voluntary isometric and eccentric torque (No stats) rate of torque development (No stats) root-mean-squared EMG (No stats) median frequency of vastus lateralis (No stats) co-activation of knee flexors (No stats) fast isometric contraction (No stats)
Matrix Rhythm Therapy vs Bobath Therapy		
Unal et al. (2021) RCT (6) Nstart=32 Nend=30 TPS=Chronic A + B vs B Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)	E: Matrix Rhythm Therapy (vibration) from thoracic spine to lower extremity + Bobath Therapy C: Bobath Therapy Duration: 60min/d, 3d/wk, for 4wks - Bobath therapy & 60min/d, 3d/wk, for 4wks - Matrix rhythm therapy	E vs C: Modified Ashworth Scale Quadriceps (+exp) Hip adductors (-) Gastrocnemius (+exp) Lower extremity total (+exp) ROM Active knee flexion (+exp) passive knee flexion (+exp) active ankle dorsiflexion (-) passive ankle dorsiflexion (+exp) active ankle plantar flexion (+exp) passive ankle plantar flexion (+exp) Static balance Single Leg Stance Test right leg (-) Single Leg Stance Test left leg (+exp) Single Leg Stance Test total (+exp) Timed Get up and go test (+exp) Gait parameters Cadence (+exp) Velocity (+exp) Left gait cycle duration (-) Right gait cycle duration (-) Left stride length (-) Right stride length (-) Left % stride length (-) Right % stride length (-) Left step length (-) Right step length (-) Left stance phase (-) Right stance phase (+exp) Left swing phase (-) Right swing phase (+exp) Left double support phase (+exp) Right double support phase (+exp) Left single support phase (+exp) Right single support phase (-) Gait cycle symmetry (-) Pelvic kinematics in gait Symmetry of pelvic tilt (-) Left pelvic tilt angle (-) right pelvic tilt angle (-) Symmetry of pelvic obliquity (-) left pelvic obliquity angle (-)

		Right pelvic obliquity angle (-) Symmetry of pelvic rotation (+exp) Left pelvic rotation angle (+exp) Right pelvic rotation angle (-)
Whole Body Vibration vs Musical Exercise Therapy		
Van Nes et al. (2006) RCT (8) Nstart=53 Nend=51 TPS=Subacute A vs B	E: Whole-body vibration + Conventional therapy C: Musical exercise therapy + Conventional therapy Duration: 30-60min/d, 3-5d Regular rehabilitation, 3min/d, 5d/wk for 6wks Whole body vibration or musical exercise therapy	E vs C: Berg Balance Scale (-) Trunk Control Test (-) Rivermead Mobility Index (-) Functional Ambulation Categories (-) Barthel Index (-) Motricity Index (-) Somatosensory Threshold (-)
Balance Training + Whole Body Vibration vs Conventional Rehabilitation		
Merkert et al. (2011) RCT (3) Nstart=66 Nend=48 TPS=Acute A + B vs C Also in Table 11 (Balance Training)	E: Vibrosphere (balance training+ whole body vibration) + conventional geriatric rehabilitation. C: Conventional geriatric rehabilitation. Duration: 15 sessions of Vibrosphere training	E vs C: Berg Balance scale (-) Functional test of Lower trunk stability (-) Tinetti Gait test (-) Timed Up and Go (-) Mini-mental State examination (-) Barthel index (-) transfer (+exp) dressing (+exp) feeding (+exp) walking (-) climbing stairs (-)
Whole Body Vibration + Treadmill Training vs Treadmill Training		
Choi et al. (2017b) RCT (8) Nstart=30 Nend=26 TPS=Chronic A + B vs C + B Also in Table 9 (Treadmill Training)	E: Whole body vibration + Treadmill training C: Exercises on platform without vibration + Treadmill training Duration: 4.5min whole body vibration/ exercises on platform without vibration + 20min treadmill training, 3x/wk, for 6wks	E vs C: 6-minute walk test (-) Walking speed (+exp) Cadence (-) Step length Affected side (+exp) Less affected side (+exp) Stride length (+exp) Single limb support Affected side (-) Less affected side (-) Double limb support (+exp)
Local Muscle Vibration vs Conventional Therapy or Sham Muscle Vibration		
Chen et al. (2023a) RCT (6) Nstart=69 Nend=64 TPS=Subacute A vs B vs 0	E1: Gastrocnemius vibration + conventional E2: Tibialis anterior vibration + conventional C: Conventional Rehab Duration: 20min/d, 5d/wk, 3wks	E1 vs C: MAS(+exp1) Clonus scale(+exp1) FAC(-) Shear modulus(+exp1) Shear wave velocity(+exp1) FMA-LE (-) mBI (-) Hmax/Mmax (-) E2 vs C: MAS(+exp2)

		Clonus scale(+exp2) FAC(+exp2) Shear modulus(-) Shear wave velocity(-) FMA-LE (-) mBI (-) Hmax/Mmax (-) E1 vs E2: MAS(-) Clonus scale(-) FAC(+exp2) Shear modulus(+exp1) Shear wave velocity(+exp1) FMA-LE (-) mBI (-) Hmax/Mmax (-)
Onal et al. (2022) RCT (5) Nstart=36 Nend=30 TPS=Chronic A vs 0	E: Plantar vibration therapy (80Hz) + conventional PT C: Conventional PT Duration: C: 60min/d, 5d/wk, 4wks conventional PT ; E: 15min vibration + 45min conventional PT/d, 3d/wk, 4wks + 60min/d, 2d/wk, 4wks conventional PT	E vs C: Overall Stability Index (+exp) Anteroposterior Stability Index (+exp) Mediolateral Stability Index (+exp) Fall risk (+exp) Berg Balance Scale (+exp) Functional Reach Test (+exp) Timed Up & Go (+exp) Trunk Impairment Scale (-) 10-Metre Walk Test (+exp)
Toscano et al. (2019) RCT (9) Nstart=22 Nend=22 TPS=Acute A vs 0	E: Repetitive Focal Muscle Vibration + Physiotherapy C: Sham Muscle Vibration + Physiotherapy Duration: 30min/d, for 3d Vibration & 60min/d for 3d - Physiotherapy	E vs C: NIH Stroke scale (+exp) Motricity index (+exp) Fugl-Meyer assessment (+exp) Modified Ashworth scale (-)
Lee et al. (2013a) RCT (7) Nstart=34 Nend=31 TPS=Chronic A vs 0	E: Standard rehabilitation programme + local vibration stimulus training C: Standard rehabilitation programme + sham local vibration stimulus training Duration: 30min/d, 5d/wk, for 6wks vibration & 80min/d, 5d/wk, for 6wks standard rehabilitation program	E vs C: Postural sway Velocity (eyes-open and eyes-closed) (+exp) Distance (eyes-open and eyes-closed) (+exp) 3-meter walk test-speed (+exp) Cadence (+exp) Paretic side step length (-) Paretic single limb support time (+exp)
Paoloni et al. (2010) RCT (8) Nstart=44 Nend=44 TPS=Chronic A vs 0	E: Segmental Muscle Vibration + Conventional Therapy C: Conventional Therapy Duration: 50min/d, 3d/wk, for 4wks general therapy & 30min, 3x/wk, for 4wks SMV	E vs C: Toe-off normal (-) Toe-off paretic (+exp) Cadence (-) Step length normal (-) Step length paretic (-) Stride length normal (-) Stride length paretic (-) Step width normal (-) Step width paretic (-) Swing velocity normal (-)

		Swing velocity paretic (-) Gait speed (-) Normal ankle angle (-) Paretic ankle angle (-) Normal knee angle (-) Paretic knee angle (-) Normal hip angle (-) Paretic hip angle (-) Ankle ROM normal (-) Ankle ROM plegic (-) Normal ankle ROM (-) Paretic ankle ROM (-) Paretic ankle plantarflexion (-) Paretic ankle dorsiflexion (+exp) EMG parameters (No stats)
Magnusson et al. (1994) RCT (3) Nstart=47 Nend=24 TPS=Chronic A vs 0	E: Vibratory stimulus applied to calf muscles or galvanic stimulation of vestibular nerves C: Conventional care Duration: 30mins	E vs C: Maintaining stance during perturbations (+exp) Sway velocity (-) Swiftness (+exp) Stiffness (+exp)
Comparing Whole-Body Vibration Intensity		
Wei et al. (2022) RCT (7) Nstart=78 Nend=72 TPS=Chronic A1 vs A2 vs 0	E1: High-frequency (26 Hz) Whole-body vibration training + Standard therapy E2: Low-frequency (13 Hz) Whole-body vibration training + Standard therapy C: Sham + standard therapy Duration: 6min/d vibration & 40min/d conventional therapy, 5d/wk, for 2wks	E1/E2 vs C: Five sit-to-stand test (+exp2, +exp1) 10-metre walking test (-) Timed-up and-go test (+exp1) Berg Balance Scale (-) E1 vs E2: Five sit-to-stand test (-) 10-metre walking test (-) Timed-up and-go test (-) Berg Balance Scale (-)
Yang et al. (2021) RCT (8) Nstart=84 Nend=80 TPS=Chronic A1 vs A2	E1: High frequency (30Hz) whole body vibration E2: Low frequency (20Hz) whole body vibration Duration: 1 session/d, 3d/wk, for 8wks	E1 vs E2: Knee extensor work non-paretic concentric (-) paretic concentric (-) non-paretic eccentric (-) paretic eccentric (+exp) Serum cross-linked N-telopeptides of type I collagen (-) 6-min walk test (-)
Liao et al. (2016) RCT (8) Nstart=84 Nend=74 TPS=Chronic A1 vs A2 vs 0	E1: Low-intensity whole-body vibration E2: High-intensity whole-body vibration C: Conventional therapy Duration: 12-18min/d, 3d/wk, for 10wks vibration sessions	E1v E2 vs C: maximal voluntary isometric contraction (paretic/nonparetic) (-) Modified Ashworth Scale (knee/ankle)(+exp) VO2 max (-) Timed Up and Go (-) 6 minute walk test (-) Mini BES Test (-) Activities-specific Balance Confidence (-) Frenchay Activity Index (-)

Whole Body Vibration vs Strength Training		
Irshad et al. (2022) RCT (7) Nstart=86 Nend=86 TPS=Chronic A vs B	E: Whole body vibration + Conventional therapy C: Squatting Training Excercises + Conventional therapy Duration: 5x/wk,6 wk WBV + 30min, 5x/wk for 6wk conventional therapy	E vs C: BBS (+exp) TUG (+exp)
Additional Comparisons from the Source Dataset		
Huang et al. (2020) RCT crossover (7) Nstart=36 Nend=36 TPS=Chronic A vs 0	E: 30 Hz Whole Body Vibration C: Non-Whole Body Vibration Duration: 5min/1session - 15 min washout	E vs C: H/M ratio (+exp) Ultrasound measurement muscle blood perfusion (+exp) muscle passive stiffness (-)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Sun et al. (2024b) RCT (6) Nstart=100 Nend=100 TPS=Not reported A + B vs B Primary listing: Table 53 (Acupuncture and Massage)	E: Vibrational and Heated Stone-Needle Therapy + Meridian Dredging Exercise C: Meridian Dredging Exercise Duration: E: 35-45 mins/d (15 mins of VHS + 20-30 mins of MDE), 3ds/wk, 4wks; Control: 20-30mins/d, 3ds/wk, 4wks	E vs C: MAS (+exp) FMA-UE (-) FMA-LE (+exp) Activity of daily living scale (-) Stroke-specific quality of life scale (-)
Onal et al. (2020) RCT (6) Nstart=34 Nend=30 TPS=Chronic A1 vs A2 Primary listing: Table 27 (Electromechanical and Robotic Devices)	E: Vibration on sole of foot C: Contact on sole of foot with No vibration Duration: 15min single treatment	E vs C: Postural Stability Test (+exp) Anteroposterior stability test (+exp) Mediolateral stability (-) Fall risk test (+exp)
Beaulieu et al. (2017) RCT crossover (6) Nstart=15 Nend=15 TPS=Chronic A vs B vs C vs 0 Primary listing: Table 36 (Repetitive Peripheral Magnetic Stimulation)	E1: Neuromuscular Electrical Stimulation E2: Repetitive Peripheral Magnetic Stimulation E3: Muscle Tendon Vibration C: Occupational Therapy Duration: 2.5-3h/d, 1d/wk - 1wk washout, 4wks	E1/E2/E3 vs C: Ankle active motor threshold (+exp2) Intracortical inhibition (+exp2) Isometric Eversion Strength (+exp2, +exp3) Range of Motion (-) Stretch reflex of plantar flexors (-)
Marin et al. (2013) RCT (8) Nstart=20 Nend=20 TPS=Chronic A + B vs A Primary listing: Table 5 (Task-Specific Training)	E: Task-Specific Training + Whole-Body Vibration Treatment (With an increase in frequency, sets, and time) C: Task-Specific Training + Sham Vibration Duration: 1-2d/wk, 12wks (17 total sessions WBV, 120min/session, 10 sessions/mo, for 3mo Task- specific sessions	E vs C: Muscle thickness (-) Berg Balance Scale (-) Maximal isometric voluntary contraction of knee extensor (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving motor recovery.	3	Guo et al. 2015; Lee 2015e; Silva et al. 2014
1a	There is conflicting evidence about the effect of Local Muscle Vibration when compared to Conventional Therapy or Sham Muscle Vibration for improving motor recovery.	2	Chen et al. 2023a; Toscano et al. 2019
1b	Gastrocnemius vibration with conventional may not have a difference in efficacy when compared to Tibialis anterior vibration with conventional for improving motor recovery.	1	Chen et al. 2023a
1b	There is conflicting evidence about the effect of Vibrational and Heated Stone-Needle Therapy with Meridian Dredging Exercise when compared to Meridian Dredging Exercise for improving motor recovery.	1	Sun et al. 2024b

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving biomechanical gait measures.	3	Sade et al. 2020; Lee 2019e; Chan et al. 2012
1b	Matrix Rhythm Therapy may not have a difference in efficacy when compared to Bobath Therapy for improving biomechanical gait measures.	1	Unal et al. 2021
1b	Whole Body Vibration with Treadmill Training may produce greater improvements in biomechanical gait measures than Treadmill Training.	1	Choi et al. 2017b
1a	Local Muscle Vibration may not have a difference in efficacy when compared to Conventional Therapy or Sham Muscle Vibration for improving biomechanical gait measures.	3	Lee et al. 2013a; Paoloni et al. 2010; Magnusson et al. 1994

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving biomechanical balance measures.	3	Lee 2019e; Tankisheva et al. 2014; Lau et al. 2012
2	Local Muscle Vibration may produce greater improvements in biomechanical balance measures than Conventional Therapy or Sham Muscle Vibration.	1	Onal et al. 2022

1b	Vibration on sole of foot may produce greater improvements in biomechanical balance measures than Contact on sole of foot with No vibration.	1	Onal et al. 2020

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving muscle strength.	7	Silva et al. 2014; Tankisheva et al. 2014; Marin et al. 2013; Brogårdh et al. 2012; Lau et al. 2012; Tihanyi et al. 2010; Tihanyi et al. 2007
1b	Whole Body Vibration may not have a difference in efficacy when compared to Musical Exercise Therapy for improving muscle strength.	1	Van Nes et al. 2006
1b	Local Muscle Vibration may produce greater improvements in muscle strength than Conventional Therapy or Sham Muscle Vibration.	1	Toscano et al. 2019
1b	Comparing Whole-Body Vibration Intensity may not have a difference in efficacy when compared to Sham with therapy for improving muscle strength.	1	Liao et al. 2016
1b	Neuromuscular Electrical Stimulation may not have a difference in efficacy when compared to Occupational Therapy for improving muscle strength.	1	Beaulieu et al. 2017
1b	Task-Specific Training with Whole-Body Vibration Treatment (With an increase in frequency, sets, and time) may not have a difference in efficacy when compared to Task-Specific Training with Sham Vibration for improving muscle strength.	1	Marin et al. 2013

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving spasticity.	6	Sales et al. 2020; Alp et al. 2018; Tankisheva et al. 2014; Pang et al. 2013; Chan et al. 2012; Brogårdh et al. 2012
1b	Matrix Rhythm Therapy may produce greater improvements in spasticity than Bobath Therapy.	1	Unal et al. 2021
1a	Local Muscle Vibration may produce greater improvements in spasticity than Conventional Therapy or Sham Muscle Vibration.	2	Chen et al. 2023a; Toscano et al. 2019
1b	Gastrocnemius vibration with conventional may not have a difference in efficacy when compared to Tibialis anterior vibration with conventional for improving spasticity.	1	Chen et al. 2023a
1b	Comparing Whole-Body Vibration Intensity may produce greater improvements in spasticity than Sham with therapy.	1	Liao et al. 2016
1b	Vibrational and Heated Stone-Needle Therapy with Meridian Dredging Exercise may produce greater improvements in spasticity than Meridian Dredging Exercise.	1	Sun et al. 2024b
1b	30 Hz Whole Body Vibration may not have a difference in efficacy when compared to Non-Whole Body Vibration for improving spasticity.	1	Huang et al. 2020

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Whole Body Vibration may produce greater improvements in range of motion than Sham Stimulation, No Stimulation, or Conventional Care.	1	Xu et al. 2024
1b	Matrix Rhythm Therapy may produce greater improvements in range of motion than Bobath Therapy.	1	Unal et al. 2021
1b	Local Muscle Vibration may not have a difference in efficacy when compared to Conventional Therapy or Sham Muscle Vibration for improving range of motion.	1	Paoloni et al. 2010

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving neurophysiological measures.	6	Duray et al. 2023; Sales et al. 2020; Silva et al. 2014; Chan et al. 2012; Tihanyi et al. 2010; Tihanyi et al. 2007
1a	Local Muscle Vibration may not have a difference in efficacy when compared to Conventional Therapy or Sham Muscle Vibration for improving neurophysiological measures.	2	Chen et al. 2023a; Paoloni et al. 2010
1b	Gastrocnemius vibration with conventional may not have a difference in efficacy when compared to Tibialis anterior vibration with conventional for improving neurophysiological measures.	1	Chen et al. 2023a
1b	High frequency (30Hz) whole body vibration may not have a difference in efficacy when compared to Low frequency (20Hz) whole body vibration for improving neurophysiological measures.	1	Yang et al. 2021
1b	Neuromuscular Electrical Stimulation may produce greater improvements in neurophysiological measures than Occupational Therapy.	1	Beaulieu et al. 2017
1b	30 Hz Whole Body Vibration may produce greater improvements in neurophysiological measures than Non-Whole Body Vibration.	1	Huang et al. 2020

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving aerobic measures.	1	Duray et al. 2023
1b	Comparing Whole-Body Vibration Intensity may not have a difference in efficacy when compared to Sham with therapy for improving aerobic measures.	1	Liao et al. 2016

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Whole Body Vibration may not have a difference in efficacy when compared to Musical Exercise Therapy for improving sensory and proprioceptive function.	1	Van Nes et al. 2006

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving activities of daily living.	2	Alp et al. 2018; Lee et al. 2017c
1b	Whole Body Vibration may not have a difference in efficacy when compared to Musical Exercise Therapy for improving activities of daily living.	1	Van Nes et al. 2006
2	There is conflicting evidence about the effect of Balance Training with Whole Body Vibration when compared to Conventional Rehabilitation for improving activities of daily living.	1	Merkert et al. 2011
1b	Local Muscle Vibration may not have a difference in efficacy when compared to Conventional Therapy or Sham Muscle Vibration for improving activities of daily living.	1	Chen et al. 2023a
1b	Gastrocnemius vibration with conventional may not have a difference in efficacy when compared to Tibialis anterior vibration with conventional for improving activities of daily living.	1	Chen et al. 2023a

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving gait speed.	8	Burq et al. 2021b; Sade et al. 2020; Lee 2019e; Alp et al. 2018; Guo et al. 2015; Chan et al. 2012; Brogårdh et al. 2012; Lau et al. 2012
1b	Matrix Rhythm Therapy may produce greater improvements in gait speed than Bobath Therapy.	1	Unal et al. 2021
1b	Whole Body Vibration with Treadmill Training may produce greater improvements in gait speed than Treadmill Training.	1	Choi et al. 2017b
1a	Local Muscle Vibration may produce greater improvements in gait speed than Conventional Therapy or Sham Muscle Vibration.	5	Chen et al. 2023a; Onal et al. 2022; Lee et al. 2013a; Paoloni et al. 2010; Magnusson et al. 1994
1b	Gastrocnemius vibration with conventional may produce greater improvements in gait speed than Tibialis anterior vibration with conventional.	1	Chen et al. 2023a

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving gait endurance.	5	Duray et al. 2023; Silva et al. 2016; Silva et al. 2014; Brogårdh et al. 2012; Lau et al. 2012
1b	Whole Body Vibration with Treadmill Training may not have a difference in efficacy when compared to Treadmill Training for improving gait endurance.	1	Choi et al. 2017b
1b	High frequency (30Hz) whole body vibration may not have a difference in efficacy when compared to Low frequency (20Hz) whole body vibration for improving gait endurance.	1	Yang et al. 2021
1b	Comparing Whole-Body Vibration Intensity may not have a difference in efficacy when compared to Sham with therapy for improving gait endurance.	1	Liao et al. 2016

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving functional mobility.	8	Ahmed Burq et al. 2021; Burq et al. 2021b; Sade et al. 2020; Lee et al. 2017c; Lee 2015e; Silva et al. 2014; Chan et al. 2012; Brogårdh et al. 2012
1b	Matrix Rhythm Therapy may produce greater improvements in functional mobility than Bobath Therapy.	1	Unal et al. 2021
1b	Whole Body Vibration may not have a difference in efficacy when compared to Musical Exercise Therapy for improving functional mobility.	1	Van Nes et al. 2006
2	Balance Training with Whole Body Vibration may not have a difference in efficacy when compared to Conventional Rehabilitation for improving functional mobility.	1	Merkert et al. 2011
1b	Local Muscle Vibration may produce greater improvements in functional mobility than Conventional Therapy or Sham Muscle Vibration.	2	Chen et al. 2023a; Onal et al. 2022
1b	There is conflicting evidence about the effect of Gastrocnemius vibration with conventional when compared to Tibialis anterior vibration with conventional for improving functional mobility.	1	Chen et al. 2023a
1b	There is conflicting evidence about the effect of High-frequency (26 Hz) Whole-body vibration training with therapy when compared to Low-frequency (13 Hz) Whole-body vibration training with therapy for improving functional mobility.	1	Wei et al. 2022
1a	Comparing Whole-Body Vibration Intensity may not have a difference in efficacy when compared to Sham with therapy for improving functional mobility.	2	Wei et al. 2022; Liao et al. 2016
1b	Whole Body Vibration may produce greater improvements in functional mobility than Strength Training.	1	Irshad et al. 2022

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving balance.	7	Xu et al. 2024; Sade et al. 2020; Lee et al. 2017c; Lee 2015e; Marin et al. 2013; Brogårdh et al. 2012; Lau et al. 2012
1b	Matrix Rhythm Therapy may produce greater improvements in balance than Bobath Therapy.	1	Unal et al. 2021
1b	Whole Body Vibration may not have a difference in efficacy when compared to Musical Exercise Therapy for improving balance.	1	Van Nes et al. 2006
2	Balance Training with Whole Body Vibration may not have a difference in efficacy when compared to Conventional Rehabilitation for improving balance.	1	Merkert et al. 2011
2	Local Muscle Vibration may produce greater improvements in balance than Conventional Therapy or Sham Muscle Vibration.	1	Onal et al. 2022
1b	High-frequency (26 Hz) Whole-body vibration training with therapy may not have a difference in efficacy when compared to Low-frequency (13 Hz) Whole-body vibration training with therapy for improving balance.	1	Wei et al. 2022

1b	Comparing Whole-Body Vibration Intensity may not have a difference in efficacy when compared to Sham with therapy for improving balance.	1	Wei et al. 2022
1b	Whole Body Vibration may produce greater improvements in balance than Strength Training.	1	Irshad et al. 2022
1b	Task-Specific Training with Whole-Body Vibration Treatment (With an increase in frequency, sets, and time) may not have a difference in efficacy when compared to Task-Specific Training with Sham Vibration for improving balance.	1	Marin et al. 2013

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Whole Body Vibration may not have a difference in efficacy when compared to Sham Stimulation, No Stimulation, or Conventional Care for improving falls and fear of falling.	1	Lau et al. 2012
2	Local Muscle Vibration may produce greater improvements in falls and fear of falling than Conventional Therapy or Sham Muscle Vibration.	1	Onal et al. 2022
1b	Comparing Whole-Body Vibration Intensity may not have a difference in efficacy when compared to Sham with therapy for improving falls and fear of falling.	1	Liao et al. 2016
1b	Vibration on sole of foot may produce greater improvements in falls and fear of falling than Contact on sole of foot with No vibration.	1	Onal et al. 2020

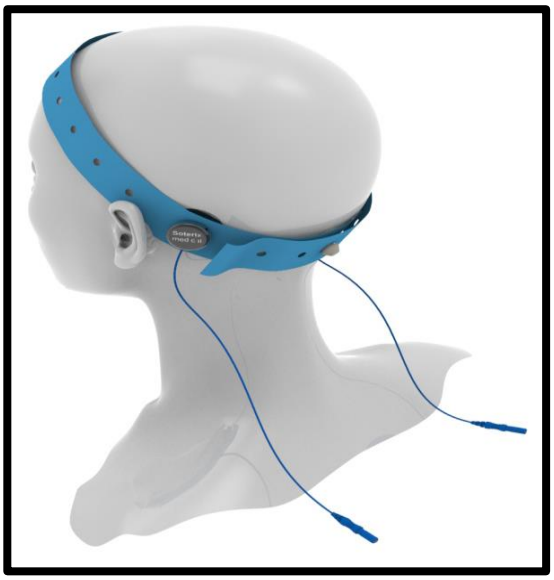
UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Vibrational and Heated Stone-Needle Therapy with Meridian Dredging Exercise may not have a difference in efficacy when compared to Meridian Dredging Exercise for improving upper extremity function.	1	Sun et al. 2024b

Key Points

- Whole Body Vibration may be beneficial for improving range of motion, but not motor recovery, biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, neurophysiological measures, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Sham Stimulation, No Stimulation, or Conventional Care.
- Matrix Rhythm Therapy may be beneficial for improving spasticity, range of motion, gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Bobath Therapy.
- Whole Body Vibration may not be beneficial for improving muscle strength, sensory and proprioceptive function, activities of daily living, functional mobility, and balance after stroke when compared to Musical Exercise Therapy.
- Balance Training with Whole Body Vibration may not be beneficial for improving functional mobility and balance after stroke when compared to Conventional Rehabilitation; the literature is mixed regarding activities of daily living.
- Whole Body Vibration with Treadmill Training may be beneficial for improving biomechanical gait measures and gait speed, but not gait endurance, after stroke when compared to Treadmill Training.
- Local Muscle Vibration may be beneficial for improving biomechanical balance measures, muscle strength, spasticity, gait speed, functional mobility, balance, and falls and fear of falling, but not biomechanical gait measures, range of motion, neurophysiological measures, and activities of daily living, after stroke when compared to Conventional Therapy or Sham Muscle Vibration; the literature is mixed regarding motor recovery.
- Gastrocnemius vibration with conventional may be beneficial for improving gait speed, but not motor recovery, spasticity, neurophysiological measures, and activities of daily living, after stroke when compared to Tibialis anterior vibration with conventional; the literature is mixed regarding functional mobility.
- High-frequency (26 Hz) Whole-body vibration training with therapy may not be beneficial for improving balance after stroke when compared to Low-frequency (13 Hz) Whole-body vibration training with therapy; the literature is mixed regarding functional mobility.
- Comparing Whole-Body Vibration Intensity may be beneficial for improving spasticity, but not functional mobility, balance, muscle strength, aerobic measures, gait endurance, and falls and fear of falling, after stroke when compared to Sham with therapy.
- High frequency (30Hz) whole body vibration may not be beneficial for improving neurophysiological measures and gait endurance after stroke when compared to Low frequency (20Hz) whole body vibration.
- Whole Body Vibration may be beneficial for improving functional mobility and balance after stroke when compared to Strength Training.
- Vibrational and Heated Stone-Needle Therapy with Meridian Dredging Exercise may be beneficial for improving spasticity, but not quality of life, after stroke when compared to Meridian Dredging Exercise; the literature is mixed regarding motor recovery.
- Vibration on sole of foot may be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Contact on sole of foot with No vibration.
- Neuromuscular Electrical Stimulation may be beneficial for improving neurophysiological measures, but not muscle strength, after stroke when compared to Occupational Therapy.
- Task-Specific Training with Whole-Body Vibration Treatment (With an increase in frequency, sets, and time) may not be beneficial for improving muscle strength and balance after stroke when compared to Task-Specific Training with Sham Vibration.
- 30 Hz Whole Body Vibration may be beneficial for improving neurophysiological measures, but not spasticity, after stroke when compared to Non-Whole Body Vibration.



Summary of Key Points: Muscle Vibration

Intervention	Control(s)	Function domain(s)	Effect

Whole Body Vibration	Sham Stimulation, No Stimulation, or Conventional Care	Range of motion	+
Whole Body Vibration	Sham Stimulation, No Stimulation, or Conventional Care	Motor recovery, biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, neurophysiological measures, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Matrix Rhythm Therapy	Bobath Therapy	Spasticity, range of motion, gait speed, functional mobility, balance	+
Matrix Rhythm Therapy	Bobath Therapy	Biomechanical gait measures	–
Whole Body Vibration	Musical Exercise Therapy	Muscle strength, sensory and proprioceptive function, activities of daily living, functional mobility, balance	–
Balance Training with Whole Body Vibration	Conventional Rehabilitation	Functional mobility, balance	–
Balance Training with Whole Body Vibration	Conventional Rehabilitation	Activities of daily living	=
Whole Body Vibration with Treadmill Training	Treadmill Training	Biomechanical gait measures, gait speed	+
Whole Body Vibration with Treadmill Training	Treadmill Training	Gait endurance	–
Local Muscle Vibration	Conventional Therapy or Sham Muscle Vibration	Biomechanical balance measures, muscle strength, spasticity, gait speed, functional mobility, balance, falls and fear of falling	+
Local Muscle Vibration	Conventional Therapy or Sham Muscle Vibration	Biomechanical gait measures, range of motion, neurophysiological measures, activities of daily living	–
Local Muscle Vibration	Conventional Therapy or Sham Muscle Vibration	Motor recovery	=
Gastrocnemius vibration with conventional	Tibialis anterior vibration with conventional	Gait speed	+
Gastrocnemius vibration with conventional	Tibialis anterior vibration with conventional	Motor recovery, spasticity, neurophysiological measures, activities of daily living	–
Gastrocnemius vibration with conventional	Tibialis anterior vibration with conventional	Functional mobility	=
High-frequency (26 Hz) Whole-body vibration training with therapy	Low-frequency (13 Hz) Whole-body vibration training with therapy	Balance	–
High-frequency (26 Hz) Whole-body vibration training with therapy	Low-frequency (13 Hz) Whole-body vibration training with therapy	Functional mobility	=
Comparing Whole-Body Vibration Intensity	Sham with therapy	Functional mobility, balance, muscle strength, aerobic measures, gait endurance, falls and fear of falling	–
High frequency (30Hz) whole body vibration	Low frequency (20Hz) whole body vibration	Neurophysiological measures, gait endurance	–

Comparing Whole-Body Vibration Intensity	Sham with therapy	Spasticity	+
Comparing Whole-Body Vibration Intensity	Sham with therapy	Muscle strength, aerobic measures, gait endurance, functional mobility, falls and fear of falling	–
Whole Body Vibration	Strength Training	Functional mobility, balance	+
Vibrational and Heated Stone-Needle Therapy with Meridian Dredging Exercise	Meridian Dredging Exercise	Spasticity	+
Vibrational and Heated Stone-Needle Therapy with Meridian Dredging Exercise	Meridian Dredging Exercise	Quality of life	–
Vibrational and Heated Stone-Needle Therapy with Meridian Dredging Exercise	Meridian Dredging Exercise	Motor recovery	=
Vibration on sole of foot	Contact on sole of foot with No vibration	Biomechanical balance measures, falls and fear of falling	+
Neuromuscular Electrical Stimulation	Occupational Therapy	Neurophysiological measures	+
Neuromuscular Electrical Stimulation	Occupational Therapy	Muscle strength	–
Task-Specific Training with Whole-Body Vibration Treatment (With an increase in frequency, sets, and time)	Task-Specific Training with Sham Vibration	Muscle strength, balance	–
30 Hz Whole Body Vibration	Non-Whole Body Vibration	Spasticity	–
30 Hz Whole Body Vibration	Non-Whole Body Vibration	Neurophysiological measures	+

Additional Afferent and Peripheral Stimulation Methods

Adopted from: https://soterixmedical.com/research/vestibular

Additional sensory stimulation methods evaluated for motor rehabilitation included short wave therapy, repetitive peripheral magnetic stimulation, intermittent pneumatic compression and other sensory stimulation techniques.

Short-wave therapy is a non-invasive intervention in which electromagnetic radiation is applied to the region of the body typically at 27.12MHz in a continuous or pulse fashion (Wang et al., 2017a). In repetitive peripheral magnetic stimulation coils are placed over paralysed muscles that generates a magnetic field that passes through the skin, and in turn can depolarize neurons to allow a muscle contraction (Momosaki et al., 2017). Repetitive peripheral magnetic stimulation can stimulate painlessly deep muscle structures that are out of range of traditional electrical stimulation (Momosaki et al., 2017). Intermittent pneumatic compression is the application of inflatable splints where pressure is applied intermittently to increase sensory input (Cambier et al., 2003).

A total of eleven RCTs were found that evaluated additional afferent and peripheral stimulation methods for lower extremity motor rehabilitation. Two RCTs compared Tactile Sensory Stimulation with Conventional Care (Goliwas et al. 2015; Lynch et al. 2007). One RCT compared Afferent Electrical Stimulation with Mirror Therapy with Sham (Lee & Lee 2019b). One RCT compared Intermittent Pneumatic Compression with Conventional Therapy (Wei et al. 2021). One RCT compared Laser Photo-biomodulation with Sham (Casalechi et al. 2020). One RCT compared Sensory Training with Trunk Training with Trunk Training Alone (Karaca et al. 2024). One RCT compared Sensory Training with Conventional Therapy (Evers et al. 2024). One RCT compared Instructed Sensory Training with TENS with Uninstructed Sensory Training with TENS (Ofek et al. 2023). One RCT compared Transcutaneous Auricular Vagus Nerve Stimulation with or without tDCS with Conventional Therapy (Wang et al. 2024a).

The methodological details and results of all eleven RCTs are presented in Table 32.

Table 32. RCTs Evaluating Additional Afferent and Peripheral Stimulation Methods for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Tactile Sensory Stimulation vs Conventional Care

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Tactile Sensory Stimulation may not have a difference in efficacy when compared to Conventional Care for improving balance.	1	Lynch et al. 2007
1b	Afferent Electrical Stimulation with Mirror Therapy may produce greater improvements in balance than Sham.	1	Lee & Lee 2019b
2	Sensory Training with Trunk Training may not have a difference in efficacy when compared to Trunk Training Alone for improving balance.	1	Karaca et al. 2024
2	Sensory Training may not have a difference in efficacy when compared to Conventional Therapy for improving balance.	1	Evers et al. 2024
1b	Transcutaneous Auricular Vagus Nerve Stimulation with or without transcranial direct current stimulation may produce greater improvements in balance than Conventional Therapy.	1	Wang et al. 2024a

FALLS AND FEAR OF FALLS			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Instructed Sensory Training with transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Uninstructed Sensory Training with transcutaneous electrical nerve stimulation for improving falls and fear of falling.	1	Ofek et al. 2023

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Instructed Sensory Training with transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to Uninstructed Sensory Training with transcutaneous electrical nerve stimulation for improving quality of life.	1	Ofek et al. 2023

Key Points

- Tactile Sensory Stimulation may not be beneficial for improving biomechanical gait measures, sensory and proprioceptive function, functional mobility, and balance after stroke when compared to Conventional Care; the literature is mixed regarding biomechanical balance measures.
- Afferent Electrical Stimulation with Mirror Therapy may be beneficial for improving muscle strength, gait speed, and balance, but not biomechanical gait measures and spasticity, after stroke when compared to Sham.
- Intermittent Pneumatic Compression may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional Therapy.
- Laser Photo-biomodulation may be beneficial for improving gait endurance and functional mobility after stroke when compared to Sham.
- Sensory Training with Trunk Training may be beneficial for improving sensory and proprioceptive function, but not activities of daily living, gait endurance, and balance, after stroke when compared to Trunk Training Alone.
- Sensory Training may not be beneficial for improving balance after stroke when compared to Conventional Therapy.
- Instructed Sensory Training with transcutaneous electrical nerve stimulation may not be beneficial for improving sensory and proprioceptive function, functional mobility, falls and fear of falling, and quality of life after stroke when compared to Uninstructed Sensory Training with transcutaneous electrical nerve stimulation.
- Transcutaneous Auricular Vagus Nerve Stimulation with or without transcranial direct current stimulation may be beneficial for improving motor recovery, biomechanical gait measures, range of motion, activities of daily living, functional mobility, and balance after stroke when compared to Conventional Therapy.
- Tactile stimulation and mobilization + task specific gait training may not be beneficial for improving muscle strength, range of motion, gait speed, and functional mobility after stroke when compared to task specific gait training + unlimited textured insole wearing.
- NeuroDevelopmental rehabilitation + Center of pressure movement track in dynamic mode may be beneficial for improving gait speed, but not biomechanical balance measures and functional mobility, after stroke when compared to Neurodevelopmental rehabilitation + Center of pressure movement track training in static mode.

Summary of Key Points: Additional Afferent and Peripheral Stimulation Methods

Intervention	Control(s)	Function domain(s)	Effect
Tactile Sensory Stimulation	Conventional Care	Biomechanical gait measures, sensory and proprioceptive function, functional mobility, balance	–
Tactile Sensory Stimulation	Conventional Care	Biomechanical balance measures	=
Afferent Electrical Stimulation with Mirror Therapy	Sham	Muscle strength, gait speed, balance	+
Afferent Electrical Stimulation with Mirror Therapy	Sham	Biomechanical gait measures, spasticity	–

Intermittent Pneumatic Compression	Conventional Therapy	Motor recovery, activities of daily living	+
Laser Photo-biomodulation	Sham	Gait endurance, functional mobility	+
Sensory Training with Trunk Training	Trunk Training Alone	Sensory and proprioceptive function	+
Sensory Training with Trunk Training	Trunk Training Alone	Activities of daily living, gait endurance, balance	–
Sensory Training	Conventional Therapy	Balance	–
Instructed Sensory Training with transcutaneous electrical nerve stimulation	Uninstructed Sensory Training with transcutaneous electrical nerve stimulation	Sensory and proprioceptive function, functional mobility, falls and fear of falling, quality of life	–
Transcutaneous Auricular Vagus Nerve Stimulation with or without transcranial direct current stimulation	Conventional Therapy	Motor recovery, biomechanical gait measures, range of motion, activities of daily living, functional mobility, balance	+
Tactile stimulation and mobilization + task specific gait training	task specific gait training + unlimited textured insole wearing	Muscle strength, range of motion, gait speed, functional mobility	–
NeuroDevelopmental rehabilitation + Center of pressure movement track in dynamic mode	Neurodevelopmental rehabilitation + Center of pressure movement track training in static mode	Gait speed	+
NeuroDevelopmental rehabilitation + Center of pressure movement track in dynamic mode	Neurodevelopmental rehabilitation + Center of pressure movement track training in static mode	Biomechanical balance measures, functional mobility	–

Remote Ischemic Conditioning

Adopted from: https://unsplash.com/

Remote ischemic conditioning (RIC) is a procedure that aims to trigger the body's natural responses against ischemic injury after a stroke and reduce the severity of the damage from the injury (Murray & Lopez, 1997). RIC is accomplished by multiple temporary reductions of blood flow to an upper or lower extremity vascular bed by chemical, mechanical or electrical stimulus (Heusch et al., 2015). After the induced ischemic procedure, physiological and homeostatic processes will upregulate natural protective factors and it is believed that this may benefit the initial injury site. It is sometimes referred to as a synthetic form of aerobic exercise as the cardio-protective benefits from both interventions share some overlap. RIC remains a controversial intervention with some benefits being observed in animal studies but little to no clinical evidence in large human trials.

A total of two RCTs were found that evaluated remote ischemic conditioning for lower extremity motor rehabilitation. Two RCTs compared Remote Ischemic Conditioning with Sham or Conventional Therapy (Durand et al. 2019; Hyngstrom et al. 2018).

The methodological details and results of all two RCTs are presented in Table 33.

Table 33. RCTs Evaluating Remote Ischemic Conditioning for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)
Remote Ischemic Conditioning vs Sham or Conventional Therapy		
Durand et al. (2019) RCT (6) Nstart=22 Nend=20 TPS=Chronic A vs 0	E: Ischemic Conditioning Training (225 mmHg) C: Sham Duration: 30min/d, 3-4d/wk, for 2wks (7 session totally)	E vs C: 10-Meter Walk Test: Self-selected walking speed (+exp) Fast walking speed (-) Knee extensor Maximum Voluntary Contractions: MVC (-) fatigue task duration (+exp) Reduction in MVC Post Fatigue (-) Resting Twitch Torque (-)
Hyngstrom et al. (2018) RCT crossover (7) Nstart=10 Nend=10 TPS=Chronic A vs 0	E: Ischemic conditioning (225mmHg) C: Sham ischemic conditioning (25mmHg) Duration: Single session: 5min of compression then 5min of rest, repeated 5 times	E vs C: Knee extensor maximum voluntary contractions (MVCs) (+exp) EMG magnitude (No stats)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Remote Ischemic Conditioning when compared to Sham or Conventional Therapy for improving gait speed.	1	Durand et al. 2019

Other Associated Outcome Measures

FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Remote Ischemic Conditioning may produce greater improvements in fatigue and sleep than Sham or Conventional Therapy.	1	Durand et al. 2019

Key Points

- Remote Ischemic Conditioning may not be beneficial for improving muscle strength and neurophysiological measures after stroke when compared to Sham or Conventional Therapy; the literature is mixed regarding gait speed.

Summary of Key Points: Remote Ischemic Conditioning

Intervention	Control(s)	Function domain(s)	Effect
Remote Ischemic Conditioning	Sham or Conventional Therapy	Muscle strength, neurophysiological measures	−
Remote Ischemic Conditioning	Sham or Conventional Therapy	Gait speed	=

Thermal Stimulation and Cryotherapy

Adopted from: https://premierhealthmn.com/services/benefits-of-ice-heat-therapy/

Thermal stimulation is a neurologic rehabilitation strategy used to facilitate sensorimotor function by applying thermal stimulation in a noxious or innocuous form on sensory receptors in the body (Lin et al., 2017). Thermal gradations can be distinguished by three types of receptors: cold, warmth, and pain receptors (Tai et al., 2014). Thermal stimulation stimulates innocuous or noxious receptors, which send the signals to several areas in the somatosensory cortex. Imaging studies show that innocuous and noxious stimulation may activate different regions of the brain: whereas innocuous stimulation seems to activate the primary and secondary somatosensory cortex, thalamus, and insula, noxious stimulation induces larger sensory and motor-cortical activations in the brain (Tai et al., 2014). Innocuous thermal stimulation has also been found to induce greater corticomotor excitability, and as such has been suggested to influence cortical reorganization and neuroplasticity (Lin et al., 2017). Cryotherapy decreases tissue temperature and can be used to reduce inflammation, pain and muscle spasms (Costello & Donnelly, 2010). Applications may include ice, water immersion and cooling pads (Costello & Donnelly, 2010).

A total of nine RCTs were found that evaluated thermal stimulation and cryotherapy for lower extremity motor rehabilitation. Six RCTs compared Thermal Stimulation with Sham or No Stimulation (Alwhaibi et al. 2021; Matsumoto et al. 2014; Hsu et al. 2013; Liang et al. 2012; Martins et al. 2012; Chen et al. 2011). One RCT compared Cryotherapy with Sham (Alcantara et al. 2019). One RCT compared Cryotherapy + Physical Therapy with Ankle foot Orthosis with Physical Therapy with Ankle foot Orthosis (Elnassag et al. 2019). One RCT compared Ankle Proprioceptive Training with Thermotherapy with Conventional Therapy (Kim et al. 2022d).

In addition, one RCT in which thermal stimulation and cryotherapy formed part of a combined or comparative intervention are cross-referenced at the end of Table 34; their primary listings appear in other tables.

The methodological details and results of all nine RCTs are presented in Table 34.

Table 34. RCTs Evaluating Thermal Stimulation and Cryotherapy for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**

Key Points

- Thermal Stimulation may be beneficial for improving motor recovery, muscle strength, neurophysiological measures, and functional mobility, but not aerobic measures, activities of daily living, and balance, after stroke when compared to Sham or No Stimulation; the literature is mixed regarding spasticity.
- Transcutaneous electrical nerve stimulation may be beneficial for improving neurophysiological measures after stroke when compared to Cryotherapy.
- Cryotherapy may be beneficial for improving spasticity, but not biomechanical gait measures and muscle strength, after stroke when compared to Sham.
- Cryotherapy with Physical Therapy with Ankle foot Orthosis may be beneficial for improving spasticity and range of motion, but not neurophysiological measures, after stroke when compared to Physical Therapy with Ankle foot Orthosis.
- Ankle Proprioceptive Training with Thermotherapy may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and balance after stroke when compared to Conventional Therapy.
- Robot guided ankle proprioceptive training with Thermal tactile stimulation and Conventional therapy may be beneficial for improving motor recovery, range of motion, gait speed, and balance after stroke when compared to Conventional Therapy.

Summary of Key Points: Thermal Stimulation and Cryotherapy

Intervention	Control(s)	Function domain(s)	Effect
Thermal Stimulation	Sham or No Stimulation	Motor recovery, muscle strength, neurophysiological measures, functional mobility	+
Thermal Stimulation	Sham or No Stimulation	Aerobic measures, activities of daily living, balance	–
Thermal Stimulation	Sham or No Stimulation	Spasticity	=
Transcutaneous electrical nerve stimulation	Cryotherapy	Neurophysiological measures	+
Cryotherapy	Sham	Spasticity	+
Cryotherapy	Sham	Biomechanical gait measures, muscle strength	–
Cryotherapy with Physical Therapy with Ankle foot Orthosis	Physical Therapy with Ankle foot Orthosis	Spasticity, range of motion	+
Cryotherapy with Physical Therapy with Ankle foot Orthosis	Physical Therapy with Ankle foot Orthosis	Neurophysiological measures	–
Ankle Proprioceptive Training with Thermotherapy	Conventional Therapy	Biomechanical gait measures, biomechanical balance measures, gait speed, balance	+
Robot guided ankle proprioceptive training with Thermal tactile stimulation and Conventional therapy	Conventional Therapy	Motor recovery, range of motion, gait speed, balance	+

Extracorporeal Shockwave Therapy and Therapeutic Ultrasound

Adopted from: https://www.sportsmedbiologic.com.au/shockwave-therapy.html

Extracorporeal shockwave therapy involves the delivery of high-intensity ultrasound waves to affected soft tissue regions of the body. When it comes to stroke treatment, this therapy is used to alleviate spasticity in stroke patients (Taheri et al. 2017). Therapeutic ultrasound may be delivered in a continuous or pulsed mode (Radinmehr et al. 2019). Continuous ultrasound provides a thermal effect, and pulsed effects are usually nonthermal (Ansari et al. 2007). The use of ultrasound has been studied in aiding spasticity.

A total of fourteen RCTs were found that evaluated extracorporeal shockwave therapy and therapeutic ultrasound for lower extremity motor rehabilitation. Six RCTs compared Extracorporeal Shockwave Therapy with Sham or Conventional Therapy (Deniz et al. 2024; Nada et al. 2024; Zhu et al. 2023; Yoldas Aslan et al. 2021; Lee et al. 2019c; Taheri et al. 2017). One RCT compared Focused Shockwave Therapy with Radial Shockwave Therapy (Wu et al. 2018). One RCT evaluated Location of Extracorporeal Shockwave Therapy (Yoon et al. 2017). Two RCTs compared Therapeutic Ultrasound with Sham or Conventional Therapy (Sahin et al. 2011; Ansari et al. 2007). One RCT compared Radial Extracorpeal Shock Wave Therapy with Visual Feedback Balance Training with Sham with Visual Feedback Balance Training (Mihai et al. 2022). One RCT compared Therapeutic Ultrasound with TENS vs Botulinum Toxin A (Picelli et al. 2014). One RCT compared Therapeutic Ultrasound with Radial Extracorporeal Shock Wave Therapy (Radinmehr et al. 2019). One RCT evaluated Comparison of Extracorporeal Shockwave Therapy Dosage (Yang et al. 2024b).

In addition, two RCTs in which extracorporeal shockwave therapy and therapeutic ultrasound formed part of a combined or comparative intervention are cross-referenced at the end of Table 35; their primary listings appear in other tables.

The methodological details and results of all fourteen RCTs are presented in Table 35.

Key Points

- Extracorporeal Shockwave Therapy may be beneficial for improving biomechanical gait measures, muscle strength, and spasticity, but not motor recovery, range of motion, neurophysiological measures, pain, activities of daily living, gait speed, and gait endurance, after stroke when compared to Sham or Conventional Therapy.
- Extracorpeal shockwave therapy may not be beneficial for improving spasticity after stroke when compared to extracorporeal shockwave therapy with Isokinetic strength training; the literature is mixed regarding neurophysiological measures.
- Focused Shockwave Therapy may not be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to Radial Shockwave Therapy.
- Extracorporeal Shock-wave Therapy on Muscle Belly (0.068 0.093 mJ/mm², 1,500 shots) may not be beneficial for improving spasticity after stroke when compared to Sham Extracorporeal Shock- wave Therapy (sound only).
- Therapeutic Ultrasound may not be beneficial for improving motor recovery, spasticity, and range of motion after stroke when compared to Sham or Conventional Therapy; the literature is mixed regarding neurophysiological measures.
- Radial Extracorpeal Shock Wave Therapy with Visual Feedback Balance Training may be beneficial for improving motor recovery, biomechanical balance measures, spasticity, and range of motion, but not balance, after stroke when compared to Sham with Visual Feedback Balance Training; the literature is mixed regarding functional mobility.
- Therapeutic ultrasound with Home exercises & conventional therapy may not be beneficial for improving spasticity and range of motion after stroke when compared to transcutaneous electrical nerve stimulation with Home exercises & conventional therapy.
- Therapeutic ultrasound with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Therapeutic ultrasound may not be beneficial for improving muscle strength, spasticity, range of motion, neurophysiological measures, and functional mobility after stroke when compared to Radial extracorporeal shock wave therapy (radial extracorporeal shockwave therapy).

- Double dose extracorporeal shockwave therapy may be beneficial for improving functional mobility, but not spasticity and range of motion, after stroke when compared to Single dose extracorpeal shockwave therapy.

Summary of Key Points: Extracorporeal Shockwave Therapy and Therapeutic Ultrasound

Intervention	Control(s)	Function domain(s)	Effect
Extracorporeal Shockwave Therapy	Sham or Conventional Therapy	Biomechanical gait measures, muscle strength, spasticity	+
Extracorporeal Shockwave Therapy	Sham or Conventional Therapy	Motor recovery, range of motion, neurophysiological measures, pain, activities of daily living, gait speed, gait endurance	–
Extracorpeal shockwave therapy	extracorporeal shockwave therapy with Isokinetic strength training	Spasticity	–
Extracorpeal shockwave therapy	extracorporeal shockwave therapy with Isokinetic strength training	Neurophysiological measures	=
Focused Shockwave Therapy	Radial Shockwave Therapy	Spasticity, range of motion, gait speed	–
Extracorporeal Shock-wave Therapy on Muscle Belly (0.068 0.093 mJ/mm², 1,500 shots)	Sham Extracorporeal Shock-wave Therapy (sound only)	Spasticity	–
Therapeutic Ultrasound	Sham or Conventional Therapy	Motor recovery, spasticity, range of motion	–
Therapeutic Ultrasound	Sham or Conventional Therapy	Neurophysiological measures	=
Radial Extracorpeal Shock Wave Therapy with Visual Feedback Balance Training	Sham with Visual Feedback Balance Training	Motor recovery, biomechanical balance measures, spasticity, range of motion	+
Radial Extracorpeal Shock Wave Therapy with Visual Feedback Balance Training	Sham with Visual Feedback Balance Training	Balance	–
Radial Extracorpeal Shock Wave Therapy with Visual Feedback Balance Training	Sham with Visual Feedback Balance Training	Functional mobility	=
Therapeutic ultrasound with Home exercises & conventional therapy	transcutaneous electrical nerve stimulation with Home exercises & conventional therapy	Spasticity, range of motion	–
Therapeutic ultrasound with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy	Spasticity, range of motion	–
Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy	Spasticity, range of motion	–
Therapeutic ultrasound	Radial extracorporeal shock wave therapy (radial extracorporeal shockwave therapy)	Muscle strength, spasticity, range of motion, neurophysiological measures, functional mobility	–
Double dose extracorporeal shockwave therapy	Single dose extracorpeal shockwave therapy	Functional mobility	+
Double dose extracorporeal shockwave therapy	Single dose extracorpeal shockwave therapy	Spasticity, range of motion	–

Repetitive Peripheral Magnetic Stimulation

Adopted from: https://www.youtube.com/watch?v=h7O5z-_eydw

Repetitive peripheral magnetic stimulation is a treatment that stimulates deep tissue through the usage of magnetic waves (Beaulieu et al. 2017). This can help patients regain function of their limbs which may have been compromised by a traumatic event such as an accident or a stroke (Beaulieu et al. 2015).

A total of three RCTs were found that evaluated repetitive peripheral magnetic stimulation for lower extremity motor rehabilitation. One RCT compared Repetitive Peripheral Magnetic Stimulation with NMES, Muscle Vibration, and Conventional therapy (Beaulieu et al. 2017). Two RCTs compared Repetitive Peripheral Magnetic Stimulation with Sham (Ke et al. 2022; Beaulieu et al. 2015).

The methodological details and results of all three RCTs are presented in Table 36.

Table 36. RCTs Evaluating Repetitive Peripheral Magnetic Stimulation for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Repetitive Peripheral Magnetic Stimulation vs NMES, Muscle Vibration, and Conventional therapy		
Beaulieu et al. (2017) RCT crossover (6) Nstart=15 Nend=15 TPS=Chronic A vs B vs C vs 0 Also in Table 29 (Neuromuscular Electrical Stimulation (NMES)); Table 31 (Muscle Vibration)	E1: Neuromuscular Electrical Stimulation E2: Repetitive Peripheral Magnetic Stimulation E3: Muscle Tendon Vibration C: Occupational Therapy Duration: 2.5-3h/d, 1d/wk - 1wk washout, 4wks	E1/E2/E3 vs C: Ankle active motor threshold (+exp2) Intracortical inhibition (+exp2) Isometric Eversion Strength (+exp2, +exp3) Range of Motion (-) Stretch reflex of plantar flexors (-)

Repetitive Peripheral Magnetic Stimulation vs Sham		
Ke et al. (2022) RCT (6) Nstart=30 Nend=26 TPS=Acute A vs 0	E: High-Frequency Repetitive Peripheral Magnetic Stimulation + conventional treatment C: Sham Repetitive Peripheral Magnetic Stimulation + conventional treatment Duration: 90 min/d, 10ds (rPMS: 30 mins/d, 10d; Conventional treatment: 60 min)	E vs C: FMA-UE total (+exp) proximal (+exp) wrist (-) hand (+exp) coordination (-) FMA-LE (+exp) The Medical Research Council scale proximal upper extremity (+exp) distal upper extremity (-) proximal lower extremity (+exp) distal lower extremity (+exp)
Beaulieu et al. (2015) RCT (5) Nstart=18 Nend=18 TPS=Chronic A vs 0	E: Repetitive peripheral magnetic stimulation C: Sham stimulation Duration: Single session	E vs C: Plantar flexor resistance to stretch (+exp) Dorsiflexor PROM (-) Dorsiflexor AROM (-) Dorsiflexor Strength (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

Key Points

- Repetitive Peripheral Magnetic Stimulation may be beneficial for improving neurophysiological measures, but not muscle strength, after stroke when compared to neuromuscular electrical stimulation, Muscle Vibration, and Conventional therapy.
- Repetitive Peripheral Magnetic Stimulation may be beneficial for improving motor recovery and muscle strength, but not range of motion, after stroke when compared to Sham.

Summary of Key Points: Repetitive Peripheral Magnetic Stimulation

Intervention	Control(s)	Function domain(s)	Effect
Repetitive Peripheral Magnetic Stimulation	neuromuscular electrical stimulation, Muscle Vibration, and Conventional therapy	Neurophysiological measures	+
Repetitive Peripheral Magnetic Stimulation	neuromuscular electrical stimulation, Muscle Vibration, and Conventional therapy	Muscle strength	−
Repetitive Peripheral Magnetic Stimulation	Sham	Motor recovery, muscle strength	+
Repetitive Peripheral Magnetic Stimulation	Sham	Range of motion	−

Repetitive Transcranial Magnetic Stimulation (rTMS)

Adopted from: https://www.rtmscentre.co.uk/rtms-treatment-in-the-uk/

Transcranial magnetic stimulation is a painless and non-invasive method of affecting neural activity through the exogenous generation of an electromagnetic field through a coil placed on the scalp, that consequently induces a change in the electrical fields of the brain (Peterchev et al., 2012). The voltage and current of the electromagnetic field generated are dependent on the parameters of the stimulation device, which is not distorted by the biological tissues in which it is applied in (Peterchev et al. 2012). The neuromodulatory effects of transcranial magnetic stimulation are attributed largely to neural membrane polarization shifts that can lead to changes in neuron activity, synaptic transmission, and activation of neural networks (Peterchev et al. 2012). Repetitive transcranial magnetic stimulation (rTMS) is the application of repetitive trains of transcranial magnetic stimulation at regular intervals.

After a stroke, interhemispheric competition is altered; with cortical excitability increasing in the unaffected hemisphere increasing and decreasing in the affected hemisphere (Zhang et al., 2017a). rTMS can be used to help modulate this interhemispheric competition, with low stimulation frequencies (≤1Hz) decreasing cortical excitability and inhibiting activity of the contralesional hemisphere, while high frequency (>1Hz) stimulation increases excitability and have a facilitatory effect on activity of the ipsilesional hemisphere (Dionisio et al., 2018).

A total of 33 RCTs were found that evaluated repetitive transcranial magnetic stimulation (rTMS) for lower extremity motor rehabilitation. Eleven RCTs compared Low frequency (1Hz) rTMS with Sham Stimulation (Wang et al. 2024d; Zhao et al. 2024; Yu et al. 2022; Chen et al. 2021c; Huang et al. 2018; Cha et al. 2017c; Meng & Song 2017; Rastgoo et al. 2016; Lin et al. 2015; Kim et al. 2014e; Wang et al. 2012). Seven RCTs compared High Frequency (>1Hz) rTMS with Sham Stimulation (Chieffo et al. 2021; Gu & Chang 2017; Guan et al. 2017; Sasaki et al. 2017; Choi et al. 2016; Chieffo et al. 2014; Kakuda et al. 2013). Four RCTs compared High Frequency rTMS or Sham rTMS with Low Frequency rTMS or Sham rTMS (Wang et al. 2020c; Du et al. 2016; Cha et al. 2014a; Khedr et al. 2010). One RCT compared Combined High and Low Frequency rTMS with Standard Therapy (Bintang et al. 2020). One RCT compared Low Frequency rTMS with tDCS or Combined rTMS and tDCS or Sham (Gong et al. 2021). Two RCTs compared High Frequency rTMS Combined with Treadmill Training with Treadmill Training (Lee et al. 2020a; Wang et al. 2019b). One RCT evaluated Ankle Strengthening Exercises With rTMS (Cha et al. 2017c). One RCT compared High Frequency rTMS with Cathodal tDCS with rTMS (Cho et al. 2017). One RCT compared Low Frequency (1Hz) rTMS with Conventional Therapy (Shu et al. 2024). One RCT compared rTMS Combined with Cycling Exercise with Cycling Exercise Alone (Wang et al. 2024b). Two RCTs compared rTMS Combined with Virtual/Augmented Reality Gait Training with Virtual/Augmented Reality Gait Training Alone (Fang et al. 2024; Zhang et al. 2024a). One RCT compared rTMS Combined with Motor Relearning with Motor Relearning Alone (Chen et al. 2023b).

In addition, two RCTs in which repetitive transcranial magnetic stimulation (rTMS) formed part of a combined or comparative intervention are cross-referenced at the end of Table 37; their primary listings appear in other tables.

The methodological details and results of all 33 RCTs are presented in Table 37.

Table 37. RCTs Evaluating Repetitive Transcranial Magnetic Stimulation (rTMS) for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)

rTMS Combined with Motor Relearning vs Motor Relearning Alone		
Chen et al. (2023b) RCT (8) Nstart=60 Nend=60 TPS=Chronic A + B vs B Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)	E: rTMS + Motor relearning procedure C: Motor relearning procedure + Conventional rehabilitation Duration: 80-90min (20min rTMS + 20-30min MRP + 40min routine)/d, 6d/wk, 4wks	E vs C: MAS (+exp) FMA LL (+exp) balance (+exp) Brunnstrom stage (+exp) Hoffer walking scale (-) MEP extration rate (+exp) threshold (+exp) latency (-) central motor conduction time (+exp)

Cross-Referenced RCTs: Combined or Comparative Interventions		
Cha et al. (2017c) RCT (7) Nstart=30 Nend=30 TPS=Subacute A1 vs A2 vs B Primary listing: Table 21 (Strength and Resistance Training)	E1: Ankle Strengthening E2: Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation (rTMS) C: rTMS Duration: 10min/d, 5d/wk, for 8wks	E2 vs C: Motor evoked potential amplitude (+exp2) plantar flexor (+exp2) Dorsiflexor (+exp2) 10-Meter walk test (+exp2) E2 vs E1: Motor evoked potential amplitude (+exp2) Plantar flexor (+exp2) Dorsiflexor (+exp2) 10-Meter walk test (+exp2)
Cha & Kim (2015) RCT (6) Nstart=36 Nend=31 TPS=Subacute A + B vs A Primary listing: Table 19 (Mirror Therapy)	E: Mirror therapy + Repetitive transcranial magnetic stimulation C: Mirror therapy + Sham stimulation Duration: 30min/d, 5d/wk for 4wks Mirror therapy & 10min/d, 5d/wk, for 4wks rTMS or Sham	E vs C: Dynamic limits of stability (+exp) Berg Balance Scale (-) Timed Up & Go Test (-) Balance Index (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Low frequency (1Hz) repetitive transcranial magnetic stimulation may produce greater improvements in upper extremity function than Sham Stimulation.	2	Zhao et al. 2024; Chen et al. 2021c
1b	Primary motor area repetitive transcranial magnetic stimulation may not have a difference in efficacy when compared to Supplementary motor area repetitive transcranial magnetic stimulation for improving upper extremity function.	1	Zhao et al. 2024
1b	High Frequency (>1Hz) repetitive transcranial magnetic stimulation may not have a difference in efficacy when compared to Sham Stimulation for improving upper extremity function.	1	Guan et al. 2017
1b	There is conflicting evidence about the effect of High frequency repetitive transcranial magnetic stimulation (10Hz) with Conventional therapy when compared to Low frequency repetitive transcranial magnetic stimulation (1Hz) with Conventional therapy for improving upper extremity function.	1	Wang et al. 2020c
1b	High Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation may produce greater improvements in upper extremity function than Low Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation.	1	Wang et al. 2020c
1b	Low frequency (3Hz) repetitive transcranial magnetic stimulation with conventional care may not have a difference in efficacy when compared to High frequency (10Hz) repetitive transcranial magnetic stimulation with conventional care for improving upper extremity function.	1	Khedr et al. 2010
1b	Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not have a difference in efficacy when compared to Sham repetitive transcranial magnetic stimulation for improving upper extremity function.	1	Gong et al. 2021
1b	Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not have a difference in efficacy when compared to Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy for improving upper extremity function.	1	Gong et al. 2021
1b	Cathodal tDCS with rTMS (1Hz) with conventional therapy may not have a difference in efficacy when compared to Anodal tDCS with rTMS (1Hz) with conventional therapy for improving upper extremity function.	1	Gong et al. 2021
1b	High Frequency repetitive transcranial magnetic stimulation with Cathodal transcranial direct current stimulation may produce greater improvements in upper extremity function than repetitive transcranial magnetic stimulation.	1	Cho et al. 2017

Key Points

- Low frequency (1Hz) repetitive transcranial magnetic stimulation may be beneficial for improving motor recovery, biomechanical gait measures, neurophysiological measures, activities of daily living, gait endurance, functional mobility, and balance, but not spasticity, gait speed, and quality of life, after stroke when compared to Sham Stimulation; the literature is mixed regarding biomechanical balance measures.
- Primary motor area repetitive transcranial magnetic stimulation may not be beneficial for improving motor recovery after stroke when compared to Supplementary motor area repetitive transcranial magnetic stimulation; Primary motor area repetitive transcranial magnetic stimulation may result in lesser improvements in neurophysiological measures and balance when compared to Supplementary motor area repetitive transcranial magnetic stimulation.
- High Frequency (>1Hz) repetitive transcranial magnetic stimulation may be beneficial for improving biomechanical balance measures, spasticity, gait speed, and balance, but not muscle strength, aerobic measures, gait endurance, and functional mobility, after stroke when compared to Sham Stimulation; the literature is mixed regarding motor recovery, neurophysiological measures, and activities of daily living.
- High frequency repetitive transcranial magnetic stimulation (10Hz) with Conventional therapy may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Low frequency repetitive transcranial magnetic stimulation (1Hz) with Conventional therapy; the literature is mixed regarding neurophysiological measures.
- High Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation may be beneficial for improving biomechanical balance measures and balance after stroke when compared to Low Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation; the literature is mixed regarding motor recovery, neurophysiological measures, and activities of daily living.
- Ipsilesional repetitive transcranial magnetic stimulation (3Hz) with Physical therapy may be beneficial for improving neurophysiological measures after stroke when compared to Contralesional repetitive transcranial magnetic stimulation (1Hz) with Physical therapy.
- Low frequency (3Hz) repetitive transcranial magnetic stimulation with conventional care may not be beneficial for improving motor recovery, neurophysiological measures, and activities of daily living after stroke when compared to High frequency (10Hz) repetitive transcranial magnetic stimulation with conventional care.
- Combined High and Low Frequency repetitive transcranial magnetic stimulation may be beneficial for improving motor recovery, but not neurophysiological measures and functional mobility, after stroke when compared to Therapy.
- Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not be beneficial for improving neurophysiological measures and activities of daily living after stroke when compared to Sham repetitive transcranial magnetic stimulation; the literature is mixed regarding motor recovery.
- Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not be beneficial for improving motor recovery, neurophysiological measures, and activities of daily living after stroke when compared to Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy.
- High Frequency repetitive transcranial magnetic stimulation Combined with Treadmill Training may be beneficial for improving motor recovery, gait speed, gait endurance, and functional mobility, but not neurophysiological measures, after stroke when compared to Treadmill Training.
- Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation may be beneficial for improving muscle strength, neurophysiological measures, and gait speed after stroke when compared to Ankle Strengthening.
- Ankle Strengthening may be beneficial for improving muscle strength, neurophysiological measures, and gait speed after stroke when compared to repetitive transcranial magnetic stimulation.
- The literature is mixed regarding the effect of High Frequency repetitive transcranial magnetic stimulation with Cathodal transcranial direct current stimulation on motor recovery after stroke when compared to repetitive transcranial magnetic stimulation.
- Low Frequency (1Hz) repetitive transcranial magnetic stimulation may be beneficial for improving biomechanical gait measures, range of motion, and neurophysiological measures after stroke when compared to Conventional Therapy.

- Repetitive transcranial magnetic stimulation Combined with Cycling Exercise may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and balance after stroke when compared to Cycling Exercise Alone.
- Repetitive transcranial magnetic stimulation Combined with Virtual/Augmented Reality Gait Training may be beneficial for improving motor recovery and gait speed, but not biomechanical gait measures, muscle strength, and neurophysiological measures, after stroke when compared to Virtual/Augmented Reality Gait Training Alone; the literature is mixed regarding balance.
- Repetitive transcranial magnetic stimulation Combined with Motor Relearning may be beneficial for improving motor recovery, spasticity, and neurophysiological measures, but not functional mobility, after stroke when compared to Motor Relearning Alone.
- Mirror therapy with Repetitive transcranial magnetic stimulation may be beneficial for improving biomechanical balance measures, but not functional mobility and balance, after stroke when compared to Mirror therapy with Sham stimulation.
- LF-rTMS with Conventional rehab may be beneficial for improving biomechanical gait measures, range of motion, activities of daily living, gait speed, and balance, but not motor recovery, after stroke when compared to Sham rTMS with Conventional rehab.
- Cathodal tDCS with rTMS (1Hz) with conventional therapy may not be beneficial for improving motor recovery, neurophysiological measures, and activities of daily living after stroke when compared to Anodal tDCS with rTMS (1Hz) with conventional therapy.
- LF-rTMS with Conventional rehab may be beneficial for improving motor recovery, biomechanical gait measures, range of motion, activities of daily living, gait speed, and balance after stroke when compared to Conventional rehab.
- Sham rTMS with Conventional rehab may be beneficial for improving motor recovery, biomechanical gait measures, range of motion, and activities of daily living, but not gait speed and balance, after stroke when compared to Conventional rehab.

Summary of Key Points: Repetitive Transcranial Magnetic Stimulation (rTMS)

Intervention	Control(s)	Function domain(s)	Effect
Low frequency (1Hz) repetitive transcranial magnetic stimulation	Sham Stimulation	Motor recovery, biomechanical gait measures, neurophysiological measures, activities of daily living, gait endurance, functional mobility, balance	+
Low frequency (1Hz) repetitive transcranial magnetic stimulation	Sham Stimulation	Spasticity, gait speed, quality of life	–
Low frequency (1Hz) repetitive transcranial magnetic stimulation	Sham Stimulation	Biomechanical balance measures	=
Primary motor area repetitive transcranial magnetic stimulation	Supplementary motor area repetitive transcranial magnetic stimulation	Motor recovery	–
Primary motor area repetitive transcranial magnetic stimulation	Supplementary motor area repetitive transcranial magnetic stimulation	Neurophysiological measures, balance	–
High Frequency (>1Hz) repetitive transcranial magnetic stimulation	Sham Stimulation	Biomechanical balance measures, spasticity, gait speed, balance	+
High Frequency (>1Hz) repetitive transcranial magnetic stimulation	Sham Stimulation	Muscle strength, aerobic measures, gait endurance, functional mobility	–
High Frequency (>1Hz) repetitive transcranial magnetic stimulation	Sham Stimulation	Motor recovery, neurophysiological measures, activities of daily living	=
High frequency repetitive transcranial magnetic stimulation (10Hz) with Conventional therapy	Low frequency repetitive transcranial magnetic stimulation (1Hz) with Conventional therapy	Motor recovery, activities of daily living	+

High Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation	Low Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation	Biomechanical balance measures, balance	+
High Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation	Low Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation	Motor recovery, neurophysiological measures, activities of daily living	=
Ipsilesional repetitive transcranial magnetic stimulation (3Hz) with Physical therapy	Contralesional repetitive transcranial magnetic stimulation (1Hz) with Physical therapy	Neurophysiological measures	+
Low frequency (3Hz) repetitive transcranial magnetic stimulation with conventional care	High frequency (10Hz) repetitive transcranial magnetic stimulation with conventional care	Motor recovery, neurophysiological measures, activities of daily living	–
Combined High and Low Frequency repetitive transcranial magnetic stimulation	Therapy	Motor recovery	+
Combined High and Low Frequency repetitive transcranial magnetic stimulation	Therapy	Neurophysiological measures, functional mobility	–
Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Sham repetitive transcranial magnetic stimulation	Neurophysiological measures, activities of daily living	–
Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Sham repetitive transcranial magnetic stimulation	Motor recovery	=
Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy	Motor recovery, neurophysiological measures, activities of daily living	–
High Frequency repetitive transcranial magnetic stimulation Combined with Treadmill Training	Treadmill Training	Motor recovery, gait speed, gait endurance, functional mobility	+
High Frequency repetitive transcranial magnetic stimulation Combined with Treadmill Training	Treadmill Training	Neurophysiological measures	–
Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation	Ankle Strengthening	Muscle strength, neurophysiological measures, gait speed	+
Ankle Strengthening	repetitive transcranial magnetic stimulation	Muscle strength, neurophysiological measures, gait speed	+
High Frequency repetitive transcranial magnetic stimulation with Cathodal transcranial direct current stimulation	repetitive transcranial magnetic stimulation	Motor recovery	=
Low Frequency (1Hz) repetitive transcranial magnetic stimulation	Conventional Therapy	Biomechanical gait measures, range of motion, neurophysiological measures	+
Repetitive transcranial magnetic stimulation Combined with Cycling Exercise	Cycling Exercise Alone	Motor recovery, biomechanical gait measures, gait speed, balance	+

Repetitive transcranial magnetic stimulation Combined with Virtual/Augmented Reality Gait Training	Virtual/Augmented Reality Gait Training Alone	Motor recovery, gait speed	+
Repetitive transcranial magnetic stimulation Combined with Virtual/Augmented Reality Gait Training	Virtual/Augmented Reality Gait Training Alone	Biomechanical gait measures, muscle strength, neurophysiological measures	–
Repetitive transcranial magnetic stimulation Combined with Virtual/Augmented Reality Gait Training	Virtual/Augmented Reality Gait Training Alone	Balance	=
Repetitive transcranial magnetic stimulation Combined with Motor Relearning	Motor Relearning Alone	Motor recovery, spasticity, neurophysiological measures	+
Repetitive transcranial magnetic stimulation Combined with Motor Relearning	Motor Relearning Alone	Functional mobility	–
Mirror therapy with Repetitive transcranial magnetic stimulation	Mirror therapy with Sham stimulation	Biomechanical balance measures	+
Mirror therapy with Repetitive transcranial magnetic stimulation	Mirror therapy with Sham stimulation	Functional mobility, balance	–
LF-rTMS with Conventional rehab	Sham rTMS with Conventional rehab	Biomechanical gait measures, range of motion, activities of daily living, gait speed, balance	+
LF-rTMS with Conventional rehab	Sham rTMS with Conventional rehab	Motor recovery	–
Cathodal tDCS with rTMS (1Hz) with conventional therapy	Anodal tDCS with rTMS (1Hz) with conventional therapy	Motor recovery, neurophysiological measures, activities of daily living	–
High frequency repetitive transcranial magnetic stimulation (10Hz) with Conventional therapy	Low frequency repetitive transcranial magnetic stimulation (1Hz) with Conventional therapy	Neurophysiological measures	=
LF-rTMS with Conventional rehab	Conventional rehab	Motor recovery, biomechanical gait measures, range of motion, activities of daily living, gait speed, balance	+
Sham rTMS with Conventional rehab	Conventional rehab	Motor recovery, biomechanical gait measures, range of motion, activities of daily living	+
Sham rTMS with Conventional rehab	Conventional rehab	Gait speed, balance	–

Theta Burst Stimulation (TBS)

Adopted from: https://www.psychiatryadvisor.com/home/depression-advisor/intermittent-theta-burst-stimulation-for-major-depressive-disorder-treatment/

Theta Burst Stimulation (TBS) is an emerging treatment modality that is a patterned form of rTMS where stimulation pulses are delivered in triplets or bursts at a high frequency (50Hz), and in a short interval (200ms), intending to mimic naturally occurring theta brain oscillations (Schwippel et al., 2019). TBS can also be used to adjust interhemispheric rivalry after a stroke and promote motor recovery through the delivery of continuous TBS (cTBS) to reduce cortical excitability in the contralesional hemisphere (600 pulses over 40 seconds); or intermittent TBS (iTBS) to increase cortical excitability in the ipsilesional hemisphere (600 pulses over 190 seconds) (Cotoi et al., 2019; Schwippel et al., 2019).

A total of eight RCTs were found that evaluated theta burst stimulation (TBS) for lower extremity motor rehabilitation. Three RCTs compared Intermittent Theta Burst Stimulation with Sham Stimulation (Liao et al. 2024; Liao et al. 2021; Lin et al. 2019). Three RCTs compared Cerebellar Intermittent Theta Burst Stimulation with Sham (Zhu et al. 2024; Xie et al. 2021a; Koch et al. 2019). One RCT compared Peripheral Intermittent Theta Burst Stimulation with Sham (El Nahas et al. 2022). One RCT evaluated Comparison of Intermittent Theta Burst Stimulation Sites (Xia et al. 2022).

The methodological details and results of all eight RCTs are presented in Table 38.

Table 38. RCTs Evaluating Theta Burst Stimulation (TBS) for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Intermittent Theta Burst Stimulation vs Sham Stimulation		
Liao et al. (2024) RCT (9) Nstart=36 Nend=34 TPS=Subacute A vs B vs 0	E1: iTBS to M1 + Conventional physiotherapy, E2: iTBS to contralateral cerebellar hemisphere + Conventional physiotherapy C: Sham iTBS + Conventional physiotherapy Duration: 3-5min/d, 5d/wk, 3wks	E1/E2 vs C: BBS (+exp1/2) FMA-LE (+exp2) TIS (-) BI (-) mRS (-) FAC (+exp1/2)

		HAMA (-) HAMD (-) MEP amplitude (+exp1/2) E1 vs E2: BBS (-) FMA-LE (+exp2) TIS (-) BI (-) mRS (no stat) FAC (no stat) HAMA (-) HAMD (-) MEP amplitude (+exp1)
Liao et al. (2021) RCT (7) Nstart=30 Nend=25 TPS=Subacute A vs 0	E: Intermittent theta-burst stimulation (iTBS) + physiotherapy C: Sham iTBS + physiotherapy Duration: 50min/d, 5d/wk, for 2wks	E vs C: Berg Balance Scale (+exp) Trunk Impairment Scale (+exp) Fugl-Meyer Assessment (-) Barthel Index (-) Corticospinal excitability Resting motor threshold (-) Cortical silent period (-) Motor-evoked potential (-)
Lin et al. (2019) RCT (8) Nstart=20 Nend=20 TPS=Chronic A vs 0	E: Intermittent Theta Burst Stimulation (5Hz) + Physiotherapy C: Sham + Physiotherapy Duration: 1200 pulses iTBS, 2d/wk, 5wks iTBS 45min/d, 2d/wk, for 5wks (10 sessions)	E vs C: Berg Balance Scale (-) I Timed Up and Go Test (-) 10-Meter Walk Test (-) Fugl-Meyer Assessment Lower extremity (-) Barthel Index (-) Biodex balance Overall index (-) Mediolateral (-) Eyes-open firm surface ()- Eyes-closed firm surface (-) Eyes-open unstable surface (-) Eyes-closed unstable surface (-)
Cerebellar Intermittent Theta Burst Stimulation vs Sham		
Zhu et al. (2024) RCT (7) Nstart=38 Nend=36 TPS=Subacute A + B vs B	E: Cerebellar Theta-burst Stimulation (iTBS) + Standardized Physical Therapy C: Sham Stimulation + Standardized Physical Therapy Duration: 2x/d iTBS + 60min Standard PT, 5ds/wk, 2wks	E vs C: FMA-LE (+exp) Berg balance scale (+exp) TUG (+exp) Barthel Index (+exp) Cadence (+exp) Stride length (+exp) Gait velocity (+exp) step length affected lower limb (+exp) healthy lower limb (-)
Xie et al. (2021a) RCT (9) Nstart=36 Nend=34 TPS=Subacute	E: Cerebellar intermittent TBS + Conventional therapy C: Sham TBS + Conventional therapy	E vs C: Fugl-Meyer assessment-lower extremity (-) 10m Walk test: Comfortable walking time (+exp) Maximum walking time (+exp)

A vs 0	Duration: 1session/d, 5d/wk, for 2wks iTBS (600 pulses/session) & 50min/d, 5d/wk, for 2wks conventional therapy	Timed Up and Go (-) Functional ambulation category (-) MEP Peak amplitude (-) Latency (-)
Koch et al. (2019) RCT (8) Nstart=36 Nend=34 TPS=Chronic A vs 0	E: Cerebellar iTBS + Physical therapy C: Sham iTBS + Physical therapy Duration: 90min/d, 7d/wk, for 3wks Physical therapy & 2 runs of CRB-iTBS/d, 7d/wk, for 3wks	E vs C: Berg Balance Scale (+exp) Fugl-Meyer Assessment (-) Barthel Index (-) Gait Analysis Step length (-) Step width (+exp) speed (No stats) Stance (-) Cortical Activity Primary motor cortex (-) posterior parietal cortex (+exp)
Peripheral Intermittent Theta Burst Stimulation vs Sham		
El Nahas et al. (2022) Feasibility/pilot RCT (8) Nstart=42 Nend=36 TPS=Chronic A vs 0	E: Peripheral intermittent theta burst stimulation (piTBS) C: Sham TBS Duration: 3-4d/wk, 8 sessions in total	E vs C: Modifed Ashworth Scale total (+exp) upper extremity (+exp) lower extremity (+exp) estimated Botulinum Toxin Dose total (+exp) upper extremity (+exp) lower extremity (+exp)
Comparison of Intermittent Theta Burst Stimulation Sites		
Xia et al. (2022) Feasibility/pilot RCT (4) Nstart=31 Nend=31 TPS=Subacute A vs B1 vs B2 Also in Table 52 (Supplements and Vitamins)	E1: iTBS unilateral cerebellar area (CB Single group), E2: iTBS Cerebellar primary motor cortex area (CB-M1 group), E3: iTBS Cerebellar Supplementary Motor Area (CB-SMA group) Duration: CB-M1/CB-SMA = 2 iTBS session; CB-Single group = 1 iTBS session	E1 vs E2 vs E3: Eyes open condition COPs (-) COPa (+exp2) ML-COPd (-) AP-COPd (+exp3) ML-COPs (-) AP-COPs (+exp2/3) ML-COPa (-) AP-COPa (+exp2) L-COPda (-) S-COPda (-) L-COPdv (-) S-COPdv (+exp2) COParea (-) summary balance score (-) Eyes closed condition COPs (-) COPa (-) ML-COPd (-) AP-COPd (-) ML-COPs (-) AP-COPs (-) ML-COPa (-)

		AP-COPa (-) L-COPda (-) S-COPda (-) L-COPdv (-) S-COPdv (-) COParea (-) summary balance score (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Intermittent Theta Burst Stimulation may not have a difference in efficacy when compared to Sham Stimulation for improving motor recovery.	3	Liao et al. 2024; Liao et al. 2021; Lin et al. 2019
1b	iTBS to M1 with Conventional physiotherapy may not have a difference in efficacy when compared to Sham iTBS with Conventional physiotherapy for improving motor recovery.	1	Liao et al. 2024
1b	iTBS to M1 with Conventional physiotherapy may result in lesser improvements in motor recovery when compared to iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy.	1	Liao et al. 2024
1b	iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy may produce greater improvements in motor recovery than Sham iTBS with Conventional physiotherapy.	1	Liao et al. 2024
1a	Cerebellar Intermittent Theta Burst Stimulation may not have a difference in efficacy when compared to Sham for improving motor recovery.	3	Zhu et al. 2024; Xie et al. 2021a; Koch et al. 2019

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Cerebellar Intermittent Theta Burst Stimulation may produce greater improvements in biomechanical gait measures than Sham.	2	Zhu et al. 2024; Koch et al. 2019

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Peripheral Intermittent Theta Burst Stimulation may produce greater improvements in spasticity than Sham.	1	El Nahas et al. 2022

NEUROPHYSIOLOGICAL MEASURES

1b	Intermittent Theta Burst Stimulation may not have a difference in efficacy when compared to Sham Stimulation for improving neurophysiological measures.	1	Liao et al. 2021
1b	iTBS to M1 with Conventional physiotherapy or iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy may produce greater improvements in neurophysiological measures than Sham iTBS with Conventional physiotherapy.	1	Liao et al. 2024
1b	iTBS to M1 with Conventional physiotherapy may produce greater improvements in neurophysiological measures than iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy.	1	Liao et al. 2024
1a	Cerebellar Intermittent Theta Burst Stimulation may not have a difference in efficacy when compared to Sham for improving neurophysiological measures.	2	Xie et al. 2021a; Koch et al. 2019

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Intermittent Theta Burst Stimulation may not have a difference in efficacy when compared to Sham Stimulation for improving activities of daily living.	3	Liao et al. 2024; Liao et al. 2021; Lin et al. 2019
1b	iTBS to M1 with Conventional physiotherapy or iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy may not have a difference in efficacy when compared to Sham iTBS with Conventional physiotherapy for improving activities of daily living.	1	Liao et al. 2024
1b	iTBS to M1 with Conventional physiotherapy may not have a difference in efficacy when compared to iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy for improving activities of daily living.	1	Liao et al. 2024
1a	There is conflicting evidence about the effect of Cerebellar Intermittent Theta Burst Stimulation when compared to Sham for improving activities of daily living.	2	Zhu et al. 2024; Koch et al. 2019

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Intermittent Theta Burst Stimulation may not have a difference in efficacy when compared to Sham Stimulation for improving gait speed.	1	Lin et al. 2019
1a	Cerebellar Intermittent Theta Burst Stimulation may produce greater improvements in gait speed than Sham.	3	Zhu et al. 2024; Xie et al. 2021a; Koch et al. 2019

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Cerebellar Intermittent Theta Burst Stimulation may not have a difference in efficacy when compared to Sham for improving functional mobility.	2	Zhu et al. 2024; Xie et al. 2021a
1b	iTBS to M1 with Conventional physiotherapy or iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy may	1	Liao et al. 2024

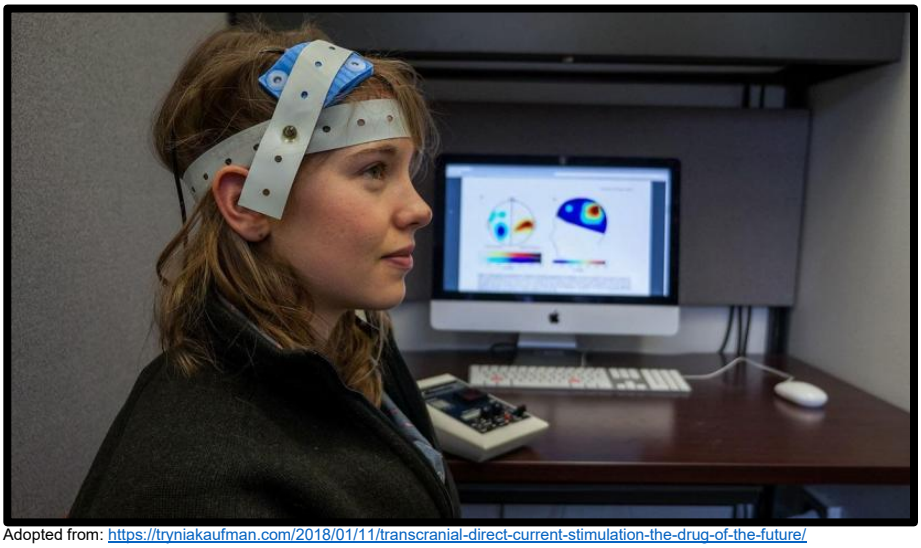
	produce greater improvements in functional mobility than Sham iTBS with Conventional physiotherapy.		

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Intermittent Theta Burst Stimulation may not have a difference in efficacy when compared to Sham Stimulation for improving balance.	3	Liao et al. 2024; Liao et al. 2021; Lin et al. 2019
1b	iTBS to M1 with Conventional physiotherapy or iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy may produce greater improvements in balance than Sham iTBS with Conventional physiotherapy.	1	Liao et al. 2024
1b	iTBS to M1 with Conventional physiotherapy may not have a difference in efficacy when compared to iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy for improving balance.	1	Liao et al. 2024
1a	Cerebellar Intermittent Theta Burst Stimulation may produce greater improvements in balance than Sham.	2	Zhu et al. 2024; Koch et al. 2019
2	Intermittent theta burst stimulation unilateral cerebellar area (CB Single group) may not have a difference in efficacy when compared to intermittent theta burst stimulation Cerebellar primary motor cortex area (CB-M1 group) or intermittent theta burst stimulation Cerebellar Supplementary Motor Area (CB-SMA group) for improving balance.	1	Xia et al. 2022

Other Associated Outcome Measures

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Peripheral Intermittent Theta Burst Stimulation may produce greater improvements in upper extremity function than Sham.	1	El Nahas et al. 2022

Key Points



- Intermittent Theta Burst Stimulation may not be beneficial for improving motor recovery, neurophysiological measures, activities of daily living, gait speed, and balance after stroke when compared to Sham Stimulation.
- Cerebellar Intermittent Theta Burst Stimulation may be beneficial for improving biomechanical gait measures, gait speed, and balance, but not motor recovery, neurophysiological measures, and functional mobility, after stroke when compared to Sham; the literature is mixed regarding activities of daily living.
- Peripheral Intermittent Theta Burst Stimulation may be beneficial for improving spasticity after stroke when compared to Sham.
- Intermittent theta burst stimulation unilateral cerebellar area (CB Single group) may not be beneficial for improving balance after stroke when compared to intermittent theta burst stimulation Cerebellar primary motor cortex area (CB-M1 group) or intermittent theta burst stimulation Cerebellar Supplementary Motor Area (CB-SMA group).
- iTBS to M1 with Conventional physiotherapy may be beneficial for improving neurophysiological measures, but not activities of daily living and balance, after stroke when compared to iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy; iTBS to M1 with Conventional physiotherapy may result in lesser improvements in motor recovery when compared to iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy.
- iTBS to M1 with Conventional physiotherapy may be beneficial for improving neurophysiological measures, functional mobility, and balance, but not motor recovery and activities of daily living, after stroke when compared to Sham iTBS with Conventional physiotherapy.

- iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy may be beneficial for improving motor recovery, neurophysiological measures, functional mobility, and balance, but not activities of daily living, after stroke when compared to Sham iTBS with Conventional physiotherapy.

Summary of Key Points: Theta Burst Stimulation (TBS)

Intervention	Control(s)	Function domain(s)	Effect
Intermittent Theta Burst Stimulation	Sham Stimulation	Motor recovery, neurophysiological measures, activities of daily living, gait speed, balance	−
Cerebellar Intermittent Theta Burst Stimulation	Sham	Biomechanical gait measures, gait speed, balance	+
Cerebellar Intermittent Theta Burst Stimulation	Sham	Motor recovery, neurophysiological measures, functional mobility	−
Cerebellar Intermittent Theta Burst Stimulation	Sham	Activities of daily living	=
Peripheral Intermittent Theta Burst Stimulation	Sham	Spasticity	+
Intermittent theta burst stimulation unilateral cerebellar area (CB Single group)	intermittent theta burst stimulation Cerebellar primary motor cortex area (CB-M1 group) or intermittent theta burst stimulation Cerebellar Supplementary Motor Area (CB-SMA group)	Balance	−
iTBS to M1 with Conventional physiotherapy	iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy	Motor recovery, activities of daily living, balance	−
iTBS to M1 with Conventional physiotherapy	iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy	Neurophysiological measures	+
iTBS to M1 with Conventional physiotherapy	Sham iTBS with Conventional physiotherapy	Neurophysiological measures, functional mobility, balance	+
iTBS to M1 with Conventional physiotherapy	Sham iTBS with Conventional physiotherapy	Motor recovery, activities of daily living	−
iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy	Sham iTBS with Conventional physiotherapy	Motor recovery, neurophysiological measures, functional mobility, balance	+
iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy	Sham iTBS with Conventional physiotherapy	Activities of daily living	−

Transcranial Direct Current Stimulation (tDCS)

Adopted from: https://tryniakaufman.com/2018/01/11/transcranial-direct-current-stimulation-the-drug-of-the-future/

Another form of non-invasive brain stimulation is transcranial direct-current stimulation (tDCS). This procedure involves the application of mild electrical currents (1-2 mA) conducted through two saline-soaked, surface electrodes applied to the scalp, overlaying the area of interest and the contralateral forehead above the orbit. Anodal stimulation is performed over the affected hemisphere and increases cortical excitability, while cathodal stimulation is performed over the unaffected hemisphere and decreases cortical excitability (Schlaug et al., 2008). Additionally, tDCS can be applied on both hemispheres concurrently, this is known as dual tDCS. In contrast to transcranial magnetic stimulation, tDCS does not induce action potentials, but instead modulates the resting membrane potential of the neurons (Cramer, 2016).

A total of 57 RCTs were found that evaluated transcranial direct current stimulation (tDCS) for lower extremity motor rehabilitation. 21 RCTs evaluated Comparison of tDCS Stimulation Conditions (Seamon et al. 2023; Wong et al. 2022; Klomjai et al. 2022; Pinto et al. 2021; Shah et al. 2021; Ojardias et al. 2020; Bornheim et al. 2020; Cattagni et al. 2019; Geiger et al. 2019; Klomjai et al. 2018; Koo et al. 2018; Utarapichat & Kitisomprayoonkul 2018; Andrade et al. 2017; Van Asseldonk & Boonstra 2016; Chang et al. 2015; Saeys et al. 2015; Fusco et al. 2014; Tahtis et al. 2014; Khedr et al. 2013; Rossi et al. 2013; Tanaka et al. 2011). Six RCTs compared tDCS with Robot-assisted Gait Training with Sham tDCS + Robot-assisted gait training (Kim et al. 2024b; Leon et al. 2017; Seo et al. 2017; Picelli et al. 2015; Danzl et al. 2013; Geroin et al. 2011). Three RCTs compared Dual tDCS + Task-oriented training with Sham tDCS + Task-oriented training (Toktas et al. 2024; Hsu et al. 2023; Aneksan et al. 2021). One RCT compared Cerebellar tDCS + Split-belt treadmill training with Sham ctDCS + Split-belt treadmill training (Kumari et al. 2020). One RCT compared tDCS + Ankle Motor Tracking + High-intensity speed-based treadmill training with High-intensity speed-based treadmill training (Madhavan et al. 2020). One RCT compared tDCS + Body weight supported treadmill training with tDCS + Body weight supported treadmill training (Manji et al. 2018). One RCT compared tDCS + Task-related training with Task-related training (Park et al. 2015b). One RCT compared tDCS + Aerobic exercise with Sham tDCS + Aerobic exercise or tDCS (Sivaramakrishnan & Madhavan 2021). One RCT compared Contralesionally Cathodal tcDCS (2mA) + Cathodal tsDCS + Robot-Assisted Gait Training with Ipsileisonally Cathodal tcDCS (2mA) + Cathodal tsDCS + Robot-Assisted Gait Training (Picelli et al. 2019). Two RCTs compared tDCS Combined with High or Low Frequency rTMS with rTMS or Sham (Gong et al. 2021; Cho et al. 2017). Three RCTs compared Transcranial Direct Current Stimulation with Functional Electrical Stimulation (Ehsani et al. 2022; Zhang et al. 2021b; Mitsutake et al. 2021). One RCT compared tDCS + Trunk Training with Sham tDCS + Trunk Training (Tedla et al. 2022). Two RCTs compared tDCS + Videogame Training with Sham tDCS + Videogame Training (Qurat-Ul-Ain et al. 2023; Qurat-ul-ain et al. 2022). Three RCTs compared tDCS + Gait Training with Sham tDCS + Gait Training (Kim et al. 2024a; Tseng et al. 2024; da Cunha et al. 2024). Three RCTs compared tDCS + Conventional Therapy with Sham tDCS + Conventional Therapy (Shakeb et al. 2024; Vimolratana et al. 2024; Duan et al. 2023). Two RCTs compared tDCS + Treadmill Training with Sham tDCS + Treadmill Training (Dumont et al. 2023; Wong et al. 2023). Two RCTs compared tDCS + Individualized Physiotherapy with Sham tDCS + Individualized Physiotherapy (Massaferri et al. 2023; Youssef et al. 2023). One RCT compared tDCS + Foot Drop Stimulator + Treadmill Training with Sham tDCS + Foot Drop Stimulator + Treadmill Training (da Cunha et al. 2022). One RCT compared tDCS + Home-Based Exercise with Sham tDCS + Home-Based Exercise (Prathum et al. 2022).

In addition, four RCTs in which transcranial direct current stimulation (tDCS) formed part of a combined or comparative intervention are cross-referenced at the end of Table 39; their primary listings appear in other tables.

The methodological details and results of all 57 RCTs are presented in Table 39.

Table 39. RCTs Evaluating Transcranial Direct Current Stimulation (tDCS) for Lower Extremity Motor Rehabilitation

Cho et al. (2017) RCT (6) Nstart=30 Nend=30 TPS=Acute A + B vs B Primary listing: Table 37 (Repetitive Transcranial Magnetic Stimulation (rTMS))	E: Dual-mode transcranial direct current stimulation (2mA) + rTMS (10Hz) C: rTMS (10Hz) Duration: 20min/d, 5d/wk for 2wks	E vs C: Fugl-Meyer assessment Lower extremity (-) upper extremity (+exp) total (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Cathodal tDCS with Conventional therapy may not have a difference in efficacy when compared to Sham tDCS with conventional rehab for improving muscle strength.	1	Klomjai et al. 2022
1b	Anodal tDCS with Conventional therapy or Dual tDCS with Conventional therapy may produce greater improvements in muscle strength than Sham tDCS with conventional rehab.	1	Klomjai et al. 2022
1b	Anodal tDCS with Conventional therapy or Cathodal tDCS with Conventional therapy may result in lesser improvements in muscle strength when compared to Dual tDCS with Conventional therapy.	1	Klomjai et al. 2022
1b	Bilateral transcranial direct current stimulation (tDCS) may not have a difference in efficacy when compared to Sham tDCS for improving muscle strength.	1	Geiger et al. 2019
1a	There is conflicting evidence about the effect of Comparison of transcranial direct current stimulation Stimulation Conditions when	2	Klomjai et al. 2018; Chang et al. 2015

	compared to Sham transcranial direct current stimulation for improving muscle strength.		
1b	Anodal transcranial direct current stimulation with Conventional care may not have a difference in efficacy when compared to Cathodal transcranial direct current stimulation with Conventional care for improving muscle strength.	1	Khedr et al. 2013
1b	Transcranial direct current stimulation with Robot-assisted Gait Training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Robot-assisted gait training for improving muscle strength.	1	Seo et al. 2017
1b	Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2.5mA) for improving muscle strength.	1	Picelli et al. 2015
1b	Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA) for improving muscle strength.	1	Picelli et al. 2015
1b	Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training may not have a difference in efficacy when compared to Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training for improving muscle strength.	1	Picelli et al. 2019
1b	Transcranial direct current stimulation with Individualized Physiotherapy may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Individualized Physiotherapy for improving muscle strength.	1	Massaferri et al. 2023
1b	Transcranial direct current stimulation with Home-Based Exercise may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Home-Based Exercise for improving muscle strength.	1	Prathum et al. 2022
1b	Cathodal cerebellar stimulation (tcDCS) with cathodal spinal stimulation (tsDCS) and Robot-assisted Gait training may produce greater improvements in muscle strength than Anodal cerebral stimulation (tDCS) with cathodal spinal stimulation (tsDCS) and Robot-assisted Gait training.	1	Picelli et al. 2018

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Comparison of transcranial direct current stimulation Stimulation Conditions may produce greater improvements in spasticity than Sham transcranial direct current stimulation.	1	Bornheim et al. 2020
1b	Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training (G-EO) with sham	1	Picelli et al. 2015

	transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2.5mA) for improving spasticity.		
1b	Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not have a difference in efficacy when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA) for improving spasticity.	1	Picelli et al. 2015
1b	Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training may not have a difference in efficacy when compared to Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training for improving spasticity.	1	Picelli et al. 2019
1b	Transcranial Direct Current Stimulation may produce greater improvements in spasticity than Functional Electrical Stimulation.	1	Ehsani et al. 2022
1b	Bihemisphere tDCS with individual physio plan may not have a difference in efficacy when compared to Unihemisphere tDCS with individual physio plan for improving spasticity.	1	Youssef et al. 2023
1b	Bihemisphere tDCS with individual physio plan or Unihemisphere tDCS with individual physio plan may not have a difference in efficacy when compared to Sham tDCS with individual PT for improving spasticity.	1	Youssef et al. 2023
1b	Transcranial direct current stimulation with Foot Drop Stimulator and Treadmill Training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Foot Drop Stimulator and Treadmill Training for improving spasticity.	1	da Cunha et al. 2022
1b	Cathodal cerebellar stimulation (tcDCS) with cathodal spinal stimulation (tsDCS) and Robot-assisted Gait training may not have a difference in efficacy when compared to Anodal cerebral stimulation (tDCS) with cathodal spinal stimulation (tsDCS) and Robot-assisted Gait training for improving spasticity.	1	Picelli et al. 2018

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Anodal tDCS may produce greater improvements in range of motion than Sham tDCS.	1	Tanaka et al. 2011
1b	Transcranial direct current stimulation with Treadmill Training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Treadmill Training for improving range of motion.	1	Dumont et al. 2023
1b	Transcutaneous auricular vagus nerve stimulation with dual transcranial direct current stimulation may produce greater improvements in range of motion than Neurodevelopmental Bobath supplemented with Occupational Therapy.	1	Wang et al. 2024a

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Anodal tDCS (2mA) may not have a difference in efficacy when compared to Sham tDCS for improving neurophysiological measures.	1	Wong et al. 2022

1b	Anodal transcranial direct current stimulation (2mA) may result in lesser improvements in neurophysiological measures when compared to Bilateral transcranial direct current stimulation (2mA) or Cathodal transcranial direct current stimulation (2mA).	1	Wong et al. 2022
1b	Bilateral transcranial direct current stimulation (2mA) may not have a difference in efficacy when compared to Cathodal transcranial direct current stimulation (2mA) for improving neurophysiological measures.	1	Wong et al. 2022
1a	There is conflicting evidence about the effect of Comparison of transcranial direct current stimulation Stimulation Conditions when compared to Sham transcranial direct current stimulation for improving neurophysiological measures.	4	Wong et al. 2022; Cattagni et al. 2019; Utarapichat & Kitisomprayoonkul 2018; Chang et al. 2015
1b	Bilateral tDCS (2mA) may produce greater improvements in neurophysiological measures than Sham tDCS.	1	Wong et al. 2022
1b	Cathodal tDCS (2mA) may produce greater improvements in neurophysiological measures than Sham tDCS.	1	Wong et al. 2022
1b	Bilateral transcranial direct current stimulation (tDCS) may not have a difference in efficacy when compared to Sham tDCS for improving neurophysiological measures.	1	Geiger et al. 2019
1b	Anodal transcranial direct current stimulation with Conventional care may not have a difference in efficacy when compared to Cathodal transcranial direct current stimulation with Conventional care for improving neurophysiological measures.	1	Khedr et al. 2013
1b	Transcranial direct current stimulation with Robot-assisted Gait Training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Robot-assisted gait training for improving neurophysiological measures.	1	Seo et al. 2017
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving neurophysiological measures.	1	Madhavan et al. 2020
1b	Transcranial direct current stimulation with Ankle Motor Tracking and High-intensity speed-based treadmill training may not have a difference in efficacy when compared to High-intensity speed-based treadmill training for improving neurophysiological measures.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High- intensity speed-based treadmill training for improving neurophysiological measures.	1	Madhavan et al. 2020
1b	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) for improving neurophysiological measures.	1	Madhavan et al. 2020
1b	Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not have a difference in efficacy when compared to 15min rest with High- intensity speed-based treadmill training for improving neurophysiological measures.	1	Madhavan et al. 2020

1b	Anodal tDCS or Aerboic exercise with Anodal tDCS may not have a difference in efficacy when compared to Aerobic exercise with Sham tDCS for improving neurophysiological measures.	1	Sivaramakrishnan & Madhavan 2021
1b	Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not have a difference in efficacy when compared to Sham repetitive transcranial magnetic stimulation for improving neurophysiological measures.	1	Gong et al. 2021
1b	Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not have a difference in efficacy when compared to Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy for improving neurophysiological measures.	1	Gong et al. 2021
1b	Cathodal tDCS with rTMS (1Hz) with conventional therapy may not have a difference in efficacy when compared to Anodal tDCS with rTMS (1Hz) with conventional therapy for improving neurophysiological measures.	1	Gong et al. 2021
1b	There is conflicting evidence about the effect of Transcranial Direct Current Stimulation when compared to Functional Electrical Stimulation for improving neurophysiological measures.	1	Ehsani et al. 2022
2	Transcranial direct current stimulation with conventional therapy may not have a difference in efficacy when compared to Functional electrical stimulation with conventional therapy for improving neurophysiological measures.	1	Zhang et al. 2021b
1b	Transcranial direct current stimulation with Gait Training may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Gait Training for improving neurophysiological measures.	1	da Cunha et al. 2024
1b	Transcranial direct current stimulation with Treadmill Training may produce greater improvements in neurophysiological measures than Sham transcranial direct current stimulation with Treadmill Training.	1	Wong et al. 2023
1b	Bilateral transcranial direct current stimulation and Treadmill may result in lesser improvements in neurophysiological measures when compared to Cathodal transcranial direct current stimulation and Treadmill.	1	Wong et al. 2023
1b	Bihemisphere tDCS with individual physio plan may not have a difference in efficacy when compared to Unihemisphere tDCS with individual physio plan for improving neurophysiological measures.	1	Youssef et al. 2023
1b	Bihemisphere tDCS with individual physio plan or Unihemisphere tDCS with individual physio plan may produce greater improvements in neurophysiological measures than Sham tDCS with individual PT.	1	Youssef et al. 2023
1b	Anodal tDCS with Conventional therapy or Cathodal tDCS with Conventional therapy or Dual tDCS with Conventional therapy may not have a difference in efficacy when compared to Sham tDCS with conventional rehab for improving neurophysiological measures.	1	Klomjai et al. 2022
1b	Anodal tDCS with Conventional therapy or Cathodal tDCS with Conventional therapy may not have a difference in efficacy when compared to Dual tDCS with Conventional therapy for improving neurophysiological measures.	1	Klomjai et al. 2022

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Transcranial direct current stimulation with Individualized Physiotherapy may not have a difference in efficacy when compared	1	Massaferri et al. 2023

	to Sham transcranial direct current stimulation with Individualized Physiotherapy for improving aerobic measures.		

SENSORY/PROPRIOCEPTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Comparison of transcranial direct current stimulation Stimulation Conditions when compared to Sham transcranial direct current stimulation for improving sensory and proprioceptive function.	2	Bornheim et al. 2020; Koo et al. 2018
1b	Anodal Cerebellar tDCS with Xbox Kinect games or Anodal M1 tDCS with Xbox Kinect games may produce greater improvements in sensory and proprioceptive function than Sham Stimulation Group with Xbox Kinect games.	1	Qurat-ul-ain et al. 2022
1b	Anodal Cerebellar tDCS with Xbox Kinect games may not have a difference in efficacy when compared to Anodal M1 tDCS with Xbox Kinect games for improving sensory and proprioceptive function.	1	Qurat-ul-ain et al. 2022

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Comparison of transcranial direct current stimulation Stimulation Conditions when compared to Sham transcranial direct current stimulation for improving activities of daily living.	5	Pinto et al. 2021; Bornheim et al. 2020; Koo et al. 2018; Fusco et al. 2014; Rossi et al. 2013

1b	There is conflicting evidence about the effect of Dual transcranial direct current stimulation with Task-oriented training when compared to Sham transcranial direct current stimulation with Task-oriented training for improving upper extremity function.	1	Hsu et al. 2023

1b	Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not have a difference in efficacy when compared to Sham repetitive transcranial magnetic stimulation for improving upper extremity function.	1	Gong et al. 2021
1b	Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not have a difference in efficacy when compared to Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy for improving upper extremity function.	1	Gong et al. 2021
1b	Cathodal tDCS with rTMS (1Hz) with conventional therapy may not have a difference in efficacy when compared to Anodal tDCS with rTMS (1Hz) with conventional therapy for improving upper extremity function.	1	Gong et al. 2021
1b	Dual-mode transcranial direct current stimulation (2mA) with repetitive transcranial magnetic stimulation (10Hz) may produce greater improvements in upper extremity function than repetitive transcranial magnetic stimulation (10Hz).	1	Cho et al. 2017
1b	Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may produce greater improvements in upper extremity function than Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy.	1	Tedla et al. 2022
1b	Transcranial direct current stimulation with Trunk Training may produce greater improvements in upper extremity function than Sham transcranial direct current stimulation with Trunk Training.	1	Tedla et al. 2022
1b	Transcranial direct current stimulation with Conventional Therapy may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Conventional Therapy for improving upper extremity function.	1	Vimolratana et al. 2024
1b	Bihemisphere tDCS with individual physio plan may not have a difference in efficacy when compared to Unihemisphere tDCS with individual physio plan for improving upper extremity function.	1	Youssef et al. 2023
1b	Bihemisphere tDCS with individual physio plan or Unihemisphere tDCS with individual physio plan may produce greater improvements in upper extremity function than Sham tDCS with individual PT.	1	Youssef et al. 2023
1b	Transcranial direct current stimulation with Home-Based Exercise may not have a difference in efficacy when compared to Sham transcranial direct current stimulation with Home-Based Exercise for improving upper extremity function.	1	Prathum et al. 2022

Key Points

- Comparison of transcranial direct current stimulation Stimulation Conditions may be beneficial for improving spasticity, but not gait speed, biomechanical balance measures, quality of life, balance, and gait endurance, after stroke when compared to Sham transcranial direct current stimulation; the literature is mixed regarding biomechanical gait measures, neurophysiological measures, motor recovery, activities of daily living, sensory and proprioceptive function, muscle strength, and functional mobility.
- Anodal tDCS (2mA) may not be beneficial for improving motor recovery, biomechanical gait measures, neurophysiological measures, and functional mobility after stroke when compared to Sham tDCS.
- Anodal transcranial direct current stimulation (2mA) may not be beneficial for improving biomechanical gait measures after stroke when compared to Bilateral transcranial direct current stimulation (2mA) or Cathodal transcranial direct current stimulation (2mA); Anodal transcranial direct current stimulation (2mA) may result in lesser improvements in neurophysiological measures and gait speed when compared

to Bilateral transcranial direct current stimulation (2mA) or Cathodal transcranial direct current stimulation (2mA).

- Bilateral transcranial direct current stimulation (2mA) may not be beneficial for improving biomechanical gait measures, neurophysiological measures, and gait speed after stroke when compared to Cathodal transcranial direct current stimulation (2mA).
- Bilateral tDCS (2mA) may be beneficial for improving biomechanical gait measures, neurophysiological measures, and gait speed, but not motor recovery, after stroke when compared to Sham tDCS.
- Cathodal tDCS (2mA) may be beneficial for improving neurophysiological measures and gait speed, but not biomechanical gait measures and motor recovery, after stroke when compared to Sham tDCS.
- Anodal transcranial direct current stimulation (2mA) with Conventional care may be beneficial for improving balance, but not quality of life, after stroke when compared to Cathodal transcranial direct current stimulation (2mA) with Conventional care.
- Bilateral transcranial direct current stimulation (tDCS) may not be beneficial for improving muscle strength and neurophysiological measures after stroke when compared to Sham tDCS.
- Dual transcranial direct current stimulation may be beneficial for improving gait endurance and functional mobility, but not biomechanical balance measures, after stroke when compared to Anodal transcranial direct current stimulation or Cathodal transcranial direct current stimulation; the literature is mixed regarding balance and falls and fear of falling.
- Anodal transcranial direct current stimulation with Conventional care may not be beneficial for improving motor recovery, muscle strength, neurophysiological measures, and activities of daily living after stroke when compared to Cathodal transcranial direct current stimulation with Conventional care.
- Anodal tDCS may be beneficial for improving range of motion, biomechanical balance measures, gait endurance, functional mobility, balance, and falls and fear of falling after stroke when compared to Sham tDCS.
- Transcranial direct current stimulation with Robot-assisted Gait Training may be beneficial for improving biomechanical gait measures and activities of daily living, but not motor recovery, muscle strength, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, and quality of life, after stroke when compared to Sham transcranial direct current stimulation with Robot-assisted gait training.
- Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not be beneficial for improving biomechanical gait measures, muscle strength, spasticity, gait endurance, and functional mobility after stroke when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2.5mA).
- Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not be beneficial for improving muscle strength, spasticity, and functional mobility after stroke when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA); Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may result in lesser improvements in biomechanical gait measures and gait endurance when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA).
- Anodal transcranial direct current stimulation with Robot- assisted gait training may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with Robot- assisted gait training.
- Dual transcranial direct current stimulation with Task-oriented training may not be beneficial for improving gait speed, functional mobility, balance, quality of life, activities of daily living, and biomechanical gait measures after stroke when compared to Sham transcranial direct current stimulation with Task-oriented training; the literature is mixed regarding motor recovery.

- Cerebellar transcranial direct current stimulation with Split-belt treadmill training may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Sham cerebellar transcranial direct current stimulation with Split-belt treadmill training.
- Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training).
- Transcranial direct current stimulation with Ankle Motor Tracking and High-intensity speed-based treadmill training may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to High-intensity speed-based treadmill training.
- Transcranial direct current stimulation with Body weight supported treadmill training may be beneficial for improving gait speed, but not motor recovery and balance, after stroke when compared to transcranial direct current stimulation with Body weight supported treadmill training; the literature is mixed regarding functional mobility.
- Transcranial direct current stimulation with Task-related training may be beneficial for improving gait speed after stroke when compared to Task-related training; the literature is mixed regarding biomechanical gait measures.
- Anodal tDCS or Aerboic exercise with Anodal tDCS may not be beneficial for improving neurophysiological measures after stroke when compared to Aerobic exercise with Sham tDCS.
- Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training may not be beneficial for improving biomechanical gait measures, muscle strength, spasticity, gait speed, and functional mobility after stroke when compared to Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training.
- Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not be beneficial for improving neurophysiological measures and activities of daily living after stroke when compared to Sham repetitive transcranial magnetic stimulation; the literature is mixed regarding motor recovery.
- Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not be beneficial for improving neurophysiological measures and activities of daily living after stroke when compared to Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy; the literature is mixed regarding motor recovery.
- The literature is mixed regarding the effect of Dual-mode transcranial direct current stimulation (2mA) with repetitive transcranial magnetic stimulation (10Hz) on motor recovery after stroke when compared to repetitive transcranial magnetic stimulation (10Hz).
- Transcranial Direct Current Stimulation may be beneficial for improving spasticity and balance after stroke when compared to Functional Electrical Stimulation; the literature is mixed regarding neurophysiological measures.
- Transcranial direct current stimulation with conventional therapy may be beneficial for improving motor recovery, activities of daily living, and functional mobility, but not neurophysiological measures, after stroke when compared to Functional electrical stimulation with conventional therapy.
- Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation with conventional rehabilitation.
- Gait training with transcranial direct current stimulation with conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation.

- Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation.
- Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may be beneficial for improving balance and quality of life, but not gait speed, after stroke when compared to Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy.
- Transcranial direct current stimulation with Trunk Training may be beneficial for improving balance and quality of life, but not gait speed, after stroke when compared to Sham transcranial direct current stimulation with Trunk Training.
- Xbox training during anodal tDCS stimulation to cerebellum may not be beneficial for improving gait speed, gait endurance, functional mobility, and falls and fear of falling after stroke when compared to Xbox training during nodal tDCS stimulation to motor cortex; Xbox training during anodal tDCS stimulation to cerebellum may result in lesser improvements in balance when compared to Xbox training during nodal tDCS stimulation to motor cortex.
- Transcranial direct current stimulation with Videogame Training may not be beneficial for improving gait endurance after stroke when compared to Sham transcranial direct current stimulation with Videogame Training.
- Transcranial direct current stimulation with Gait Training may not be beneficial for improving activities of daily living, functional mobility, quality of life, biomechanical balance measures, motor recovery, and neurophysiological measures after stroke when compared to Sham transcranial direct current stimulation with Gait Training; the literature is mixed regarding balance.
- Transcranial direct current stimulation with Conventional Therapy may be beneficial for improving balance and gait speed, but not quality of life, after stroke when compared to Sham transcranial direct current stimulation with Conventional Therapy; the literature is mixed regarding functional mobility and motor recovery.
- Transcranial direct current stimulation with Treadmill Training may be beneficial for improving motor recovery and neurophysiological measures, but not range of motion and functional mobility, after stroke when compared to Sham transcranial direct current stimulation with Treadmill Training; the literature is mixed regarding biomechanical gait measures and gait speed.
- Bilateral transcranial direct current stimulation and Treadmill may not be beneficial for improving motor recovery, biomechanical gait measures, and functional mobility after stroke when compared to Cathodal transcranial direct current stimulation and Treadmill; the literature is mixed regarding gait speed; Bilateral transcranial direct current stimulation and Treadmill may result in lesser improvements in neurophysiological measures when compared to Cathodal transcranial direct current stimulation and Treadmill.
- Transcranial direct current stimulation with Individualized Physiotherapy may not be beneficial for improving motor recovery, muscle strength, aerobic measures, and gait speed after stroke when compared to Sham transcranial direct current stimulation with Individualized Physiotherapy.
- Bihemisphere tDCS with individual physio plan may not be beneficial for improving motor recovery, spasticity, neurophysiological measures, and balance after stroke when compared to Unihemisphere tDCS with individual physio plan.
- Transcranial direct current stimulation with Foot Drop Stimulator and Treadmill Training may not be beneficial for improving spasticity, gait endurance, functional mobility, and quality of life after stroke when compared to Sham transcranial direct current stimulation with Foot Drop Stimulator and Treadmill Training.
- Transcranial direct current stimulation with Home-Based Exercise may not be beneficial for improving motor recovery, muscle strength, gait endurance, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with Home-Based Exercise.
- Transcutaneous auricular vagus nerve stimulation with dual transcranial direct current stimulation may be beneficial for improving motor recovery, biomechanical gait measures, range of motion, activities of daily living, functional mobility, and balance after stroke when compared to Neurodevelopmental Bobath supplemented with Occupational Therapy.

- Cathodal tDCS with rTMS (1Hz) with conventional therapy may not be beneficial for improving motor recovery, neurophysiological measures, and activities of daily living after stroke when compared to Anodal tDCS with rTMS (1Hz) with conventional therapy.
- Anodal tDCS with Conventional therapy may not be beneficial for improving motor recovery, neurophysiological measures, and functional mobility after stroke when compared to Dual tDCS with Conventional therapy; Anodal tDCS with Conventional therapy may result in lesser improvements in muscle strength when compared to Dual tDCS with Conventional therapy.
- Cathodal tDCS with Conventional therapy may not be beneficial for improving motor recovery and neurophysiological measures after stroke when compared to Dual tDCS with Conventional therapy; Cathodal tDCS with Conventional therapy may result in lesser improvements in muscle strength and functional mobility when compared to Dual tDCS with Conventional therapy.
- Dual tDCS may be beneficial for improving biomechanical balance measures, gait endurance, functional mobility, balance, and falls and fear of falling after stroke when compared to Sham tDCS.
- Cathodal tDCS may be beneficial for improving biomechanical balance measures, gait endurance, functional mobility, balance, and falls and fear of falling after stroke when compared to Sham tDCS.
- Anodal tDCS with Conventional therapy may be beneficial for improving muscle strength, but not motor recovery, neurophysiological measures, and functional mobility, after stroke when compared to Sham tDCS with conventional rehab.
- Cathodal tDCS with Conventional therapy may not be beneficial for improving motor recovery, muscle strength, neurophysiological measures, and functional mobility after stroke when compared to Sham tDCS with conventional rehab.
- Dual tDCS with Conventional therapy may be beneficial for improving muscle strength and functional mobility, but not motor recovery and neurophysiological measures, after stroke when compared to Sham tDCS with conventional rehab.
- Xbox training during anodal tDCS stimulation to cerebellum may be beneficial for improving gait speed, functional mobility, and balance, but not falls and fear of falling, after stroke when compared to Sham tDCS with xbox training.
- Xbox training during nodal tDCS stimulation to motor cortex may be beneficial for improving balance, but not gait speed, functional mobility, and falls and fear of falling, after stroke when compared to Sham tDCS with xbox training.
- AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to 15min rest with High- intensity speed-based treadmill training.
- AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training).
- Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may be beneficial for improving quality of life, but not motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, after stroke when compared to 15min rest with High- intensity speed-based treadmill training.
- Aerboic exercise with Anodal tDCS may not be beneficial for improving neurophysiological measures after stroke when compared to Aerobic exercise with Sham tDCS.
- Anodal tDCS may not be beneficial for improving neurophysiological measures after stroke when compared to Aerobic exercise with Sham tDCS.
- Anodal Cerebellar tDCS with Xbox Kinect games may be beneficial for improving falls and fear of falling, but not sensory and proprioceptive function, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Anodal M1 tDCS with Xbox Kinect games.
- Anodal Cerebellar tDCS with Xbox Kinect games may be beneficial for improving sensory and proprioceptive function, functional mobility, balance, and falls and fear of falling, but not gait speed, after stroke when compared to Sham Stimulation Group with Xbox Kinect games.

- Anodal M1 tDCS with Xbox Kinect games may be beneficial for improving sensory and proprioceptive function, functional mobility, and balance, but not gait speed and falls and fear of falling, after stroke when compared to Sham Stimulation Group with Xbox Kinect games.
- Bihemisphere tDCS with individual physio plan or Unihemisphere tDCS with individual physio plan may be beneficial for improving motor recovery, neurophysiological measures, and balance, but not spasticity, after stroke when compared to Sham tDCS with individual PT.
- Cathodal cerebellar stimulation (tcDCS) with cathodal spinal stimulation (tsDCS) and Robot-assisted Gait training may be beneficial for improving biomechanical gait measures, muscle strength, and gait endurance, but not spasticity and functional mobility, after stroke when compared to Anodal cerebral stimulation (tDCS) with cathodal spinal stimulation (tsDCS) and Robot-assisted Gait training.

Summary of Key Points: Transcranial Direct Current Stimulation (tDCS)

Intervention	Control(s)	Function domain(s)	Effect
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Gait speed, biomechanical balance measures, quality of life, balance, gait endurance	–
Anodal tDCS (2mA)	Sham tDCS	Motor recovery, biomechanical gait measures, neurophysiological measures, functional mobility	–
Anodal transcranial direct current stimulation (2mA)	Bilateral transcranial direct current stimulation (2mA) or Cathodal transcranial direct current stimulation (2mA)	Biomechanical gait measures	–
Anodal transcranial direct current stimulation (2mA)	Bilateral transcranial direct current stimulation (2mA) or Cathodal transcranial direct current stimulation (2mA)	Neurophysiological measures, gait speed	–
Bilateral transcranial direct current stimulation (2mA)	Cathodal transcranial direct current stimulation (2mA)	Biomechanical gait measures, neurophysiological measures, gait speed	–
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Gait speed	–
Bilateral tDCS (2mA)	Sham tDCS	Biomechanical gait measures, neurophysiological measures, gait speed	+
Cathodal tDCS (2mA)	Sham tDCS	Neurophysiological measures, gait speed	+
Cathodal tDCS (2mA)	Sham tDCS	Biomechanical gait measures, motor recovery	–
Anodal transcranial direct current stimulation (2mA) with Conventional care	Cathodal transcranial direct current stimulation (2mA) with Conventional care	Balance	+
Anodal transcranial direct current stimulation (2mA) with Conventional care	Cathodal transcranial direct current stimulation (2mA) with Conventional care	Quality of life	–
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Biomechanical balance measures, gait speed	–
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Spasticity	+

Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Quality of life	–
Bilateral transcranial direct current stimulation (tDCS)	Sham tDCS	Muscle strength, neurophysiological measures	–
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Functional mobility, biomechanical gait measures, neurophysiological measures, motor recovery, activities of daily living, sensory and proprioceptive function, muscle strength	=
Dual transcranial direct current stimulation	Anodal transcranial direct current stimulation or Cathodal transcranial direct current stimulation	Gait endurance, functional mobility	+
Dual transcranial direct current stimulation	Anodal transcranial direct current stimulation or Cathodal transcranial direct current stimulation	Biomechanical balance measures	–
Dual transcranial direct current stimulation	Anodal transcranial direct current stimulation or Cathodal transcranial direct current stimulation	Balance, falls and fear of falling	=
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Gait speed, balance	–
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Biomechanical gait measures	=
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Balance	–
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Gait speed, gait endurance	–
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation	Functional mobility	=
Anodal transcranial direct current stimulation with Conventional care	Cathodal transcranial direct current stimulation with Conventional care	Motor recovery, muscle strength, neurophysiological measures, activities of daily living	–
Anodal tDCS	Sham tDCS	Range of motion, biomechanical balance measures, gait endurance, functional mobility, balance, falls and fear of falling	+
Transcranial direct current stimulation with Robot-assisted Gait Training	Sham transcranial direct current stimulation with Robot-assisted gait training	Biomechanical gait measures, activities of daily living	+
Transcranial direct current stimulation with Robot-assisted Gait Training	Sham transcranial direct current stimulation with Robot-assisted gait training	Motor recovery, muscle strength, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, quality of life	–
Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal	Biomechanical gait measures, muscle strength, spasticity, gait endurance, functional mobility	–

transcutaneous spinal direct current stimulation	transcutaneous spinal direct current stimulation (2.5mA)		
Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA)	Muscle strength, spasticity, functional mobility	–
Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA)	Biomechanical gait measures, gait endurance	–
Anodal transcranial direct current stimulation with Robot- assisted gait training	Sham transcranial direct current stimulation with Robot- assisted gait training	Biomechanical gait measures, gait speed, gait endurance, functional mobility	–
Dual transcranial direct current stimulation with Task-oriented training	Sham transcranial direct current stimulation with Task-oriented training	Gait speed, functional mobility, balance, quality of life, activities of daily living, biomechanical gait measures	–
Dual transcranial direct current stimulation with Task-oriented training	Sham transcranial direct current stimulation with Task-oriented training	Activities of daily living	–
Dual transcranial direct current stimulation with Task-oriented training	Sham transcranial direct current stimulation with Task-oriented training	Biomechanical gait measures, gait speed, functional mobility	–
Cerebellar transcranial direct current stimulation with Split-belt treadmill training	Sham cerebellar transcranial direct current stimulation with Split-belt treadmill training	Biomechanical gait measures, gait speed	–
Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training)	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training)	Motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Transcranial direct current stimulation with Ankle Motor Tracking and High-intensity speed-based treadmill training	High-intensity speed-based treadmill training	Motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Transcranial direct current stimulation with Body weight supported treadmill training	transcranial direct current stimulation with Body weight supported treadmill training	Gait speed	+
Transcranial direct current stimulation with Body weight supported treadmill training	transcranial direct current stimulation with Body weight supported treadmill training	Motor recovery, balance	–

Transcranial direct current stimulation with Body weight supported treadmill training	transcranial direct current stimulation with Body weight supported treadmill training	Functional mobility	=
Transcranial direct current stimulation with Task-related training	Task-related training	Gait speed	+
Transcranial direct current stimulation with Task-related training	Task-related training	Biomechanical gait measures	=
Anodal tDCS or Aerboic exercise with Anodal tDCS	Aerobic exercise with Sham tDCS	Neurophysiological measures	–
Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training	Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training	Biomechanical gait measures, muscle strength, spasticity, gait speed, functional mobility	–
Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Sham repetitive transcranial magnetic stimulation	Neurophysiological measures, activities of daily living	–
Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Sham repetitive transcranial magnetic stimulation	Motor recovery	=
Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy	Neurophysiological measures, activities of daily living	–
Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy	Motor recovery	=
Dual-mode transcranial direct current stimulation (2mA) with repetitive transcranial magnetic stimulation (10Hz)	repetitive transcranial magnetic stimulation (10Hz)	Motor recovery	=
Transcranial Direct Current Stimulation	Functional Electrical Stimulation	Spasticity, balance	+
Transcranial Direct Current Stimulation	Functional Electrical Stimulation	Neurophysiological measures	=
Transcranial direct current stimulation with conventional therapy	Functional electrical stimulation with conventional therapy	Motor recovery, activities of daily living, functional mobility	+
Transcranial direct current stimulation with conventional therapy	Functional electrical stimulation with conventional therapy	Neurophysiological measures	–
Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation	Gait training with transcranial direct current stimulation with conventional rehabilitation	Biomechanical gait measures, gait speed	–

Gait training with transcranial direct current stimulation with conventional rehabilitation	Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation	Biomechanical gait measures, gait speed	−
Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation	Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation	Biomechanical gait measures, gait speed	−
Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy	Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy	Balance, quality of life	+
Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy	Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy	Gait speed	−
Transcranial direct current stimulation with Trunk Training	Sham transcranial direct current stimulation with Trunk Training	Balance, quality of life	+
Transcranial direct current stimulation with Trunk Training	Sham transcranial direct current stimulation with Trunk Training	Gait speed	−
Xbox training during anodal tDCS stimulation to cerebellum	Xbox training during nodal tDCS stimulation to motor cortex	Gait speed, gait endurance, functional mobility, balance, falls and fear of falling	−
Transcranial direct current stimulation with Videogame Training	Sham transcranial direct current stimulation with Videogame Training	Gait endurance	−
Transcranial direct current stimulation with Gait Training	Sham transcranial direct current stimulation with Gait Training	Activities of daily living, functional mobility, quality of life	−
Transcranial direct current stimulation with Gait Training	Sham transcranial direct current stimulation with Gait Training	Balance	=
Transcranial direct current stimulation with Gait Training	Sham transcranial direct current stimulation with Gait Training	Biomechanical balance measures	−
Transcranial direct current stimulation with Gait Training	Sham transcranial direct current stimulation with Gait Training	Motor recovery, neurophysiological measures, functional mobility	−
Transcranial direct current stimulation with Conventional Therapy	Sham transcranial direct current stimulation with Conventional Therapy	Balance, gait speed	+
Transcranial direct current stimulation with Conventional Therapy	Sham transcranial direct current stimulation with Conventional Therapy	Quality of life	−
Transcranial direct current stimulation with Conventional Therapy	Sham transcranial direct current stimulation with Conventional Therapy	Gait speed	+
Transcranial direct current stimulation with Treadmill Training	Sham transcranial direct current stimulation with Treadmill Training	Range of motion, functional mobility	−
Bilateral transcranial direct current stimulation and Treadmill	Cathodal transcranial direct current stimulation and Treadmill	Motor recovery, biomechanical gait measures, neurophysiological measures, functional mobility	−
Bilateral transcranial direct current stimulation and Treadmill	Cathodal transcranial direct current stimulation and Treadmill	Gait speed	=

Transcranial direct current stimulation with Treadmill Training	Sham transcranial direct current stimulation with Treadmill Training	Motor recovery, neurophysiological measures	+
Transcranial direct current stimulation with Treadmill Training	Sham transcranial direct current stimulation with Treadmill Training	Functional mobility	−
Transcranial direct current stimulation with Individualized Physiotherapy	Sham transcranial direct current stimulation with Individualized Physiotherapy	Motor recovery, muscle strength, aerobic measures, gait speed	−
Bihemisphere tDCS with individual physio plan	Unihemisphere tDCS with individual physio plan	Motor recovery, spasticity, neurophysiological measures, balance	−
Transcranial direct current stimulation with Foot Drop Stimulator and Treadmill Training	Sham transcranial direct current stimulation with Foot Drop Stimulator and Treadmill Training	Spasticity, gait endurance, functional mobility, quality of life	−
Transcranial direct current stimulation with Home-Based Exercise	Sham transcranial direct current stimulation with Home-Based Exercise	Motor recovery, muscle strength, gait endurance, functional mobility	−
Transcutaneous auricular vagus nerve stimulation with dual transcranial direct current stimulation	Neurodevelopmental Bobath supplemented with Occupational Therapy	Motor recovery, biomechanical gait measures, range of motion, activities of daily living, functional mobility, balance	+
Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2.5mA)	Spasticity	−
Cathodal tDCS with rTMS (1Hz) with conventional therapy	Anodal tDCS with rTMS (1Hz) with conventional therapy	Motor recovery, neurophysiological measures, activities of daily living	−
Bilateral tDCS (2mA)	Sham tDCS	Motor recovery	−
Anodal tDCS with Conventional therapy	Dual tDCS with Conventional therapy	Motor recovery, muscle strength, neurophysiological measures, functional mobility	−
Cathodal tDCS with Conventional therapy	Dual tDCS with Conventional therapy	Motor recovery, muscle strength, neurophysiological measures, functional mobility	−
Dual tDCS	Sham tDCS	Biomechanical balance measures, gait endurance, functional mobility, balance, falls and fear of falling	+
Cathodal tDCS	Sham tDCS	Biomechanical balance measures, gait endurance, functional mobility, balance, falls and fear of falling	+
Anodal tDCS with Conventional therapy	Sham tDCS with conventional rehab	Muscle strength	+
Anodal tDCS with Conventional therapy	Sham tDCS with conventional rehab	Motor recovery, neurophysiological measures, functional mobility	−
Cathodal tDCS with Conventional therapy	Sham tDCS with conventional rehab	Motor recovery, muscle strength, neurophysiological measures, functional mobility	−
Dual tDCS with Conventional therapy	Sham tDCS with conventional rehab	Muscle strength, functional mobility	+
Dual tDCS with Conventional therapy	Sham tDCS with conventional rehab	Motor recovery, neurophysiological measures	−

Bihemisphere tDCS with individual physio plan or Unihemisphere tDCS with individual physio plan	Sham tDCS with individual PT	Motor recovery, neurophysiological measures, balance	+
Bihemisphere tDCS with individual physio plan or Unihemisphere tDCS with individual physio plan	Sham tDCS with individual PT	Spasticity	–
Xbox training during anodal tDCS stimulation to cerebellum	Sham tDCS with xbox training	Gait speed, functional mobility, balance	+
Xbox training during anodal tDCS stimulation to cerebellum	Sham tDCS with xbox training	Falls and fear of falling	–
Xbox training during nodal tDCS stimulation to motor cortex	Sham tDCS with xbox training	Balance	+
Xbox training during nodal tDCS stimulation to motor cortex	Sham tDCS with xbox training	Gait speed, functional mobility, falls and fear of falling	–
Dual transcranial direct current stimulation with Task-oriented training	Sham transcranial direct current stimulation with Task-oriented training	Motor recovery	=
Transcranial direct current stimulation with Conventional Therapy	Sham transcranial direct current stimulation with Conventional Therapy	Functional mobility, motor recovery	=
Transcranial direct current stimulation with Treadmill Training	Sham transcranial direct current stimulation with Treadmill Training	Biomechanical gait measures, gait speed	=
Bilateral transcranial direct current stimulation and Treadmill	Cathodal transcranial direct current stimulation and Treadmill; Bilateral transcranial direct current stimulation and Treadmill may result in lesser improvements in neurophysiological measures when compared to Cathodal transcranial direct current stimulation and Treadmill	Motor recovery, biomechanical gait measures, gait speed, functional mobility	–
AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training)	15min rest with High- intensity speed-based treadmill training	Motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training)	Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training)	Motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, quality of life	–
Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training)	15min rest with High- intensity speed-based treadmill training	Motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling	–
Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training)	15min rest with High- intensity speed-based treadmill training	Quality of life	+
Aerboic exercise with Anodal tDCS	Aerobic exercise with Sham tDCS	Neurophysiological measures	–
Anodal tDCS	Aerobic exercise with Sham tDCS	Neurophysiological measures	–

Anodal Cerebellar tDCS with Xbox Kinect games	Anodal M1 tDCS with Xbox Kinect games	Falls and fear of falling	+
Anodal Cerebellar tDCS with Xbox Kinect games	Anodal M1 tDCS with Xbox Kinect games	Sensory and proprioceptive function, gait speed, gait endurance, functional mobility, balance	–
Anodal Cerebellar tDCS with Xbox Kinect games	Sham Stimulation Group with Xbox Kinect games	Sensory and proprioceptive function, functional mobility, balance, falls and fear of falling	+
Anodal Cerebellar tDCS with Xbox Kinect games	Sham Stimulation Group with Xbox Kinect games	Gait speed	–
Anodal M1 tDCS with Xbox Kinect games	Sham Stimulation Group with Xbox Kinect games	Sensory and proprioceptive function, functional mobility, balance	+
Anodal M1 tDCS with Xbox Kinect games	Sham Stimulation Group with Xbox Kinect games	Gait speed, falls and fear of falling	–
Cathodal cerebellar stimulation (tcDCS) with cathodal spinal stimulation (tsDCS) and Robot-assisted Gait training	Anodal cerebral stimulation (tDCS) with cathodal spinal stimulation (tsDCS) and Robot-assisted Gait training	Biomechanical gait measures, muscle strength, gait endurance	+

Antidepressants

Adopted from https://www.abc.net.au/news/2018-09-18/common-antidepressants-may-fuel-growth-of-super-bugs-study-says/10246000

Antidepressants of various kinds are available for medical use, including tricyclics (TCAs), monoamine oxidase inhibitors (MAOIs), selective serotonin reuptake inhibitors (SSRIs), serotonin-noradrenaline reuptake inhibitors (SNRIs, such as venlafaxine, duloxetine and milnacipran), and other agents (mirtazapine, reboxetine, bupropion). SSRIs and SNRIs are two commonly prescribed agents that work by acting to inhibit the reuptake of serotonin and norepinephrine, respectively, from the synaptic cleft (Cipriani et al., 2012). Fluoxetine, citalopram and escitalopram are commonly prescribed selective serotonin reuptake inhibitors (SSRI). There has been interest in examining the effectiveness of pharmacological interventions for motor recovery after stroke. Antidepressants may be helpful in recovery after stroke through improving mood, which may in turn improve activity and functional outcome, but also through modulating cerebral sensory-motor activation.

A total of eight RCTs were found that evaluated antidepressants for lower extremity motor rehabilitation. Four RCTs compared Fluoxetine with Placebo (Hankey et al. 2020; Marquez-Romero et al. 2020; Shah et al. 2016; Chollet et

al. 2011). One RCT compared Fluoxetine vs Placebo with Maprotiline vs Placebo (Dam et al. 1996). One RCT compared Shu-Gan-Jie-Yu vs Placebo with Fluoxetine vs Placebo (Gong et al. 2020). One RCT compared Escitalopram with Placebo (Gourab et al. 2015). One RCT compared Citalopram vs Placebo with Fluoxetine vs Placebo (Asadollahi et al. 2018).

In addition, one RCT in which antidepressants formed part of a combined or comparative intervention are cross-referenced at the end of Table 40; their primary listings appear in other tables.

The methodological details and results of all eight RCTs are presented in Table 40.

Table 40. RCTs Evaluating Antidepressants for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Fluoxetine vs Placebo		
Hankey et al. (2020) RCT (10) Nstart=1280 Nend=1256 TPS=Acute A vs 0	E: Fluoxetine (20mg) C: Placebo Duration: 20mg/d, for 6mo	E vs C: Modified Rankin Scale (-) Stroke Impact Scale Strength (-) Hand ability (-) Mobility (-) Motor (-) Daily activities (-) Physical function (-) Memory (-) Communication (-) Mood and emotional control (+exp) Participation (-) Recovery (VAS) (-) EQ-5D-5L (-) Mood (PHQ-9) (-) SF-36Fatigue (subscale) (-)
Marquez-Romero et al. (2020) RCT (7) Nstart=32 Nend=30 TPS=Acute A vs 0	E: Receiving 20 mg/day of fluoxetine C: Placebo Duration: 90 days	E vs C: Fugl-Meyer Motor Scale (+exp) National Institutes of Health stroke scale (-) Barthel Index (+exp) Modified Rankin scale (+exp)
Shah et al. (2016) RCT (6) Nstart=89 Nend=84 TPS=Acute A vs 0	E: Fluoxetine (10mg to start, increase to 20mg/d after 1wk) C: Placebo Duration: 3mo	E vs C: Fugl-Meyer Assessment (+exp) Modified Rankin Scale (-)
Chollet et al. (2011) RCT (8) Nstart=118 Nend=113 TPS=Acute A vs 0	E: Fluoxetine (20mg/d) + standard physiotherapy C: Placebo + standard physiotherapy Duration: 1/d, 90d medications	E vs C: Fugl-Meyer Assessment (+exp) Upper Extremity (+exp) Lower Extremity (+exp) Modified Rankin Scale (+exp) National Institute of Health Stroke Scale (-)

Fluoxetine vs Maprotiline vs Placebo		
Dam et al. (1996) RCT (5) Nstart=52 Nend=46 TPS=Subacute A vs B vs 0	E1: Fluoxetine (20mg/d) E2: Maprotiline (150mg/d) C: Placebo Duration: 12wks	E1 vs E2: Barthel Index (+exp1) Hemispheric Stroke Scale Gait score (+exp1) Hamilton Depression Rating Scale (-) E1/E2 vs C: Barthel Index (-) Hemispheric Stroke Scale (-) Hamilton Depression Rating Scale (-)
Shu-Gan-Jie-Yu vs Fluoxetine vs Placebo		
Gong et al. (2020) RCT (7) Nstart=254 Nend=222 TPS=Acute A1 vs B vs A2 vs 0	E1: Shu-Gan-Jie-Yu capsule, 720 mg E2: Fluoxetine, 20 mg PO daily E3: Shu-Gan-Jie-Yu (2160 mg daily) C: Placebo Duration: E1: 720 mg, 3/d, 7d/wk, for 12wks (2160 mg daily) Shu-Gan-Jie-Yu; E2: 20mg 1/d, 7d/wk, for 12wks fluoxetine; E3: 720 mg, 3/d, 7d/wk, for 12wks (2160 mg daily) Shu-Gan-Jie-Yu + 20mg 1/d, 7d/wk, for 12wks fluoxetine	E1/E2/E3 v C: Modified Rankin Scale (+exp1, +exp2, +exp3) Fugl-Meyer Motor (+exp1, +exp2, +exp3)
Escitalopram vs Placebo		
Gourab et al. (2015) RCT crossover (8) Nstart=11 Nend=10 TPS=Chronic A vs 0	E: Escitalopram (10mg) C: Placebo Duration: Single dose, 1wk washout	E vs C: Stretch reflex high stretch velocity (+exp) Fugl-Meyer Assessment (-) 6-Minute Walk Test (-) 10-m walk test (Fast) (-) Muscle strength peak torque Ankle dorsiflexion (-) ankle plantarflexion (-) knee flexion (-) knee extension (-) Medial gastrocnemius EMG activity (-)
Citalopram vs Fluoxetine vs Placebo		
Asadollahi et al. (2018) RCT (8) Nstart=90 Nend=75 TPS=Acute A vs B vs 0	E1: 20mg/d Citalopram & Physiotherapy E2: 20mg/day Fluoxetine & Physiotherapy C: Placebo & Physiotherapy 1/d, for 90d medication/placebo & 1hr/d, 5d/wk, for 12wks PT	E1 vs E2: Fugl-Meyer Motor Scale (-) E1/E2 vs C: Fugl-Meyer Motor Scale (+exp1, +exp2)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Gong et al. (2020) RCT (7) Nstart=254 Nend=222 TPS=Acute A1 vs B vs A2 vs 0 Primary listing: Table 55 (Traditional Herbal Medicines)	E1: Shu-Gan-Jie-Yu capsule, 720 mg E2: Fluoxetine, 20 mg PO daily E3: Shu-Gan-Jie-Yu (2160 mg daily) C: Placebo Duration: E1: 720 mg, 3/d, 7d/wk, 12wks (2160 mg daily) Shu-Gan- Jie-Yu; E2: 20mg 1/d, 7d/wk, for 12wks fluoxetine; E3: 720 mg, 3/d, 7d/wk, for 12wks (2160 mg daily) Shu-Gan-Jie-Yu + 20mg 1/d, 7d/wk, for 12wks fluoxetine	E1/E2/E3 vs C: Modified Rankin Scale (+exp1, +exp2, +exp3) Fugl-Meyer Motor (+exp1, +exp2, +exp3)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group
+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group
+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group
- indicates no statistically significant between groups differences at α=0.05
no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

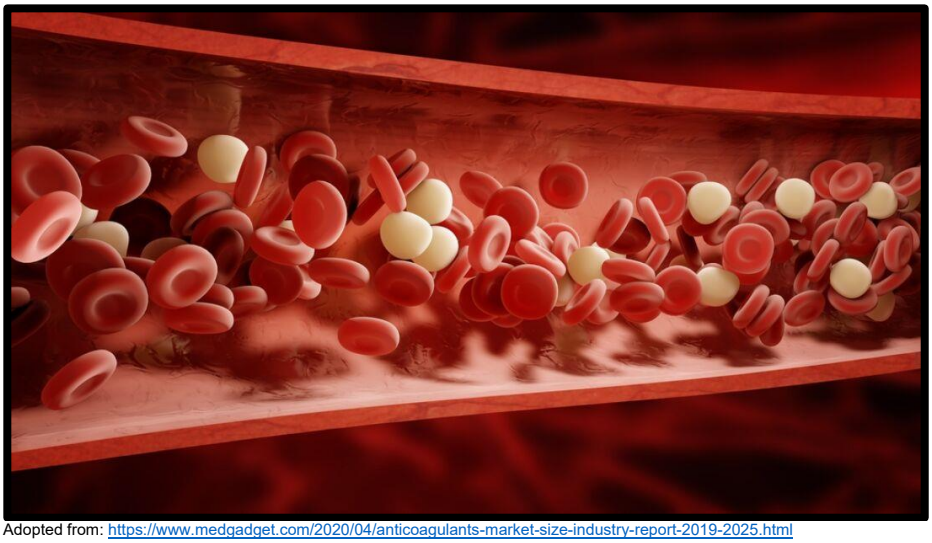
Key Points



- Fluoxetine may be beneficial for improving activities of daily living, but not quality of life, after stroke when compared to Placebo; the literature is mixed regarding motor recovery.
- Fluoxetine (20mg/d) may be beneficial for improving activities of daily living after stroke when compared to Maprotiline (150mg/d); the literature is mixed regarding motor recovery.
- Fluoxetine vs Placebo may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Maprotiline or Placebo.
- Escitalopram may not be beneficial for improving motor recovery, muscle strength, range of motion, gait speed, and gait endurance after stroke when compared to Placebo; the literature is mixed regarding neurophysiological measures.
- 20mg/d Citalopram & Physiotherapy may not be beneficial for improving motor recovery after stroke when compared to 20mg/day Fluoxetine & Physiotherapy.
- Fluoxetine (20mg/d) may not be beneficial for improving activities of daily living after stroke when compared to Placebo.
- Maprotiline (150mg/d) may not be beneficial for improving activities of daily living after stroke when compared to Placebo.
- 20mg/d Citalopram & Physiotherapy may be beneficial for improving motor recovery after stroke when compared to Placebo & Physiotherapy 1/d, for 90d medication/placebo & 1hr/d, 5d/wk, for 12wks PT.
- 20mg/day Fluoxetine & Physiotherapy may be beneficial for improving motor recovery after stroke when compared to Placebo & Physiotherapy 1/d, for 90d medication/placebo & 1hr/d, 5d/wk, for 12wks PT.
- Fluoxetine (20 mg) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Shu-Gan-Jie-Yu (2160 mg daily) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Shu-Gan-Jie-Yu capsule (720 mg) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.

Secondary Prevention Medications

Adopted from: https://www.medgadget.com/2020/04/anticoagulants-market-size-industry-report-2019-2025.html

Approximately 25% of stroke patients will face a second stroke (Esenwa & Gutierrez, 2015). In addition, many stroke patients face reduced mobility which can lead to increased risk of muscle atrophy in the chronic phase, even if a secondary event does not occur (Naritomi et al., 2010). As such, recovery and secondary prevention is critical for reducing the likelihood of a further injury and increasing quality of life.

Secondary prevention is often a comprehensive approach to managing cardiovascular risk factors such as hypertension, diabetes, dyslipidemia, and smoking cessation. Changes in lifestyle like a healthy diet and aerobic exercise are also recommended strategies (Esenwa & Gutierrez, 2015). Pharmaceuticals such as antithrombotic agents and vasodilators can be deployed to help address these risk factors and manage disease while promoting recovery.

Antithrombotic agents aim to reduce the likelihood of blood clot formation by modulating the clotting cascade but can pose risk to causing a hemorrhagic event. As such, care must be taken in selecting the appropriate agent on a case-by-case basis. However, there is evidence that they can be beneficial for preventing secondary recurrence (Del Brutto et al., 2019). Vasodilators are a class of medications that help open blood vessels all around the body. This causes increased blood flow to targeted areas of the body which can lead to increased strength and endurance thereby promoting recovery (Di Cesare et al. 2016).

A total of seven RCTs were found that evaluated secondary prevention medications for lower extremity motor rehabilitation. One RCT compared Tirofiban with Placebo (Bai et al. 2018). One RCT compared PF-3049423 with Placebo (Di Cesare et al. 2016). One RCT compared Olmesartan with Amlodipine (Matsumoto et al. 2009). One RCT compared Naftidrofuryl fumarate with Placebo (Gray 1990). One RCT compared Nimodipine with Placebo

(Kaste et al. 1994). One RCT compared DLBS1033 (Lumbrokinase) with Conventional Therapy (Pinzon et al. 2020). One RCT compared Alteplase with Aspirin (Sun et al. 2024a).

The methodological details and results of all seven RCTs are presented in Table 41.

Table 41. RCTs Evaluating Secondary Prevention Medications for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)
Tirofiban vs Placebo		
Bai et al. (2018) RCT (7) Nstart=66 Nend=60 TPS=Acute A vs 0	E: Tirofiban injection + Conventional Rehabilitation C: Placebo injection + Conventional Rehabilitation Duration: 1/d, for 3wks Tirofiban/sham injection & 180min/d, 5d/wk, for 3wks Conventional Rehabilitation	E vs C: Fugl-Meyer Assessment (+exp) Sensorimotor network connectivity (-) Diffusivity of corticospinal tract (-)
PF-3049423 vs Placebo		
Di Cesare et al. (2016) RCT (6) Nstart=139 Nend=137 TPS=Acute A vs 0	E: PF-3049423 Phosphodiesterase-5 Inhibitor (6mg) C: Placebo Duration: 1/d, for 90d	E vs C: Modified Rankin scale (-) Barthel index (-) National Institute for Health Stroke Severity (-) Box Block test (-) Hand-grip strength (-) 10-Meter Walk test (-) Repeatable Battery assessment of Neuropsychological status (-) Modified Albert's test (-)
Olmesartan vs Amlodipine		
Matsumoto et al. (2009) RCT (6) Nstart=35 Nend=35 TPS=Subacute A vs B	E: Olmesartan (10mg) C: Amlodipine (2.5mg with dose increase as needed) Duration: 8wks	E vs C: Brunnstrom Stage Total (+exp) Lower extremity (+exp) Barthel Index (-) Mini-Mental State Examination (-) Blood Pressure (-)
Naftidrofuryl fumarate vs Placebo		
Gray (1990) RCT (5) Nstart=100 Nend=89 TPS=Acute A vs 0	E: Naftidrofuryl fumarate (316.5 mg) C: Placebo Duration: 12 wks	E vs C: Cumulative fatality (-) Hospital-bed occupancy (-) Recovery of motor function (-)
Nimodipine vs Placebo		
Kaste et al. (1994) RCT (6) Nstart=350	E: Nimodipine taken orally (120 mg/d) C: Placebo Duration: 30mg, 4doses/d, 120mg total/d, for 21d	E vs C: Rankin Grades (-) Mobility (-)

Nend=299 TPS=Acute A vs 0		Neurological Score (-)
DLBS1033 (Lumbrokinase) vs Conventional Therapy		
Pinzon et al. (2020) RCT (6) Nstart=60 Nend=54 TPS=Acute A vs 0 Also in Table 52 (Supplements and Vitamins)	E: DLBS1033 supplement (Lumbrokinase) + Standard therapy C: Standard therapy Duration: 3doses/d - DLBS1033 until discharge	E vs C: Modified rankin scale (+exp) National institute of health stroke scale (+exp) Barthel index (+exp) physiological and lab tests (No stats)
Alteplase vs Aspirin		
Sun et al. (2024a) RCT (5) Nstart=60 Nend=60 TPS=Acute A vs B	E: Alteplase IV thrombolysis + conventional care C: Aspirin + conventional care Duration: E: 0.9mg/kg; C: 0.3g-0.1g/d, for 2 wks	E vs C: NIHSS (+exp) BI (+exp) FMA (+exp) Berg Balance Scale (+exp) MoCA (+exp) mRS (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

Edaravone

Adopted from: https://www.newswire.ca/news-releases/mitsubishi-tanabe-pharma-canada-announces-that-company-s-treatment-for-amyotrophic-lateral-sclerosis-als-has-been-added-to-the-provincial-drug-plan-in-alberta-816188000.html

Edaravone (Radicava, Radicut) is a small-molecule drug that with antioxidant properties and has been hypothesized to be beneficial for stroke recovery. It is thought to act as a free-radical scavenger and reduce the oxidative stress that accompanies muscle paralysis following stroke and subsequently improve leg locomotor function (Naritomi et al. 2010; Petrov et al., 2017). However, the precise mechanism of action remains unknown. Edaravone has been approved for use early-stage ALS patients in Japan and is seeking approval for acute stroke in other nations. There remains very limited clinical data for stroke recovery despite some promising pre-clinical studies.

A total of two RCTs were found that evaluated edaravone for lower extremity motor rehabilitation. One RCT compared Long-Term Edaravone with Short-Term Edaravone (Naritomi et al. 2010). One RCT compared Edaravone Injection with Conventional Treatment (Sun et al. 2019).

The methodological details and results of all two RCTs are presented in Table 42.

Table 42. RCTs Evaluating Edaravone for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Long-Term Edaravone vs Short-Term Edaravone		
Naritomi et al. (2010) RCT (5) Nstart=47 Nend=41 TPS=Acute A vs B	E1: Short term intravenous Edaravone (30mg) + Conventional care E2: Long term intravenous Edaravone (30mg) + Conventional care Duration: 30mg 2x/d, 3 days for short term, 10-14 days for long term	E1 vs E2: Disuse muscle atrophy Paretic leg (+exp2) Non-paretic leg (+exp2) Brunnstrom Recovery Stage (-) 10-Metre Walk Test (+exp2)
Edaravone Injection vs Conventional Treatment		
Sun et al. (2019) RCT (6) Nstart=130 Nend=130 TPS=Acute	E: Edaravone injection (30 mg edaravone) + Conventional Treatment (80mg Ligustrazine in 250mL 0.9% sodium chloride and 100mg aspirin tab) C: Conventional Treatment Duration: E: 30mins/d, 2x/d, for 2wks	E vs C: Adverse events (-) Barthel Index (+exp) Fugl-Meyer Assessment (+exp)

A vs 0 vs B	C: 30mins/d, 1x/d, for 2wks	National Institute of Health Stroke Scale (+exp) Total treatment Efficacy (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Long term intravenous Edaravone (30mg) with Conventional care may not have a difference in efficacy when compared to Short term intravenous Edaravone (30mg) with Conventional care for improving motor recovery.	1	Naritomi et al. 2010
1b	Edaravone Injection may produce greater improvements in motor recovery than Conventional Treatment.	1	Sun et al. 2019

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Long term intravenous Edaravone (30mg) with Conventional care may produce greater improvements in muscle strength than Short term intravenous Edaravone (30mg) with Conventional care.	1	Naritomi et al. 2010

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Edaravone Injection may produce greater improvements in activities of daily living than Conventional Treatment.	1	Sun et al. 2019

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Long term intravenous Edaravone (30mg) with Conventional care may produce greater improvements in gait speed than Short term intravenous Edaravone (30mg) with Conventional care.	1	Naritomi et al. 2010

Key Points

- Edaravone Injection may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional Treatment.
- Long term intravenous Edaravone (30mg) with Conventional care may be beneficial for improving muscle strength and gait speed, but not motor recovery, after stroke when compared to Short term intravenous Edaravone (30mg) with Conventional care.

Summary of Key Points: Edaravone

Intervention	Control(s)	Function domain(s)	Effect
Edaravone Injection	Conventional Treatment	Motor recovery, activities of daily living	+
Long term intravenous Edaravone (30mg) with Conventional care	Short term intravenous Edaravone (30mg) with Conventional care	Muscle strength, gait speed	+
Long term intravenous Edaravone (30mg) with Conventional care	Short term intravenous Edaravone (30mg) with Conventional care	Motor recovery	−

Stimulants

Adopted from: https://www.verywellmind.com/is-ritalin-addictive-21911

Stimulants are drugs that increase cortical excitability in the central nervous system (CNS), often by blocking reuptake and increasing the synaptic concentration and transmission of dopamine, serotonin, and noradrenaline throughout the brain. The neurobehavioral gains ascribed to CNS stimulants include enhanced arousal, mental processing speed, and/or motor processing speed (Herrold et al., 2014).

Two stimulants that are commonly used in rehabilitation include amphetamines and methylphenidates. Amphetamines are sympathomimetic agents that possess potent CNS stimulant effects by releasing monoamines from presynaptic neurons in the brain (Martinsson & Eksborg, 2004). They have been shown to improve motor recovery after brain injury in animal studies, and there is increasing evidence that they may provide symptomatic management for some deficits after brain injury in humans (Walker-Batson et al., 1995). Methylphenidates stimulate the CNS by increasing synaptic concentrations of norepinephrine and dopamine and are thought to modulate cerebral reorganization and improve motor function in stroke patients (Wang et al., 2014b).

A total of ten RCTs were found that evaluated stimulants for lower extremity motor rehabilitation. Seven RCTs compared Amphetamines with Placebo (Goldstein et al. 2018; Gladstone et al. 2006; Martinsson & Wahlgren 2003a; Treig et al. 2003; Sonde et al. 2001; Walker-Batson 1995; Crisostomo et al. 1988). One RCT compared Amphetamine with Intensive Physiotherapy with Amphetamine with Conventional Physiotherapy (Martinsson et al. 2003b). One RCT compared Amphetamine vs Placebo with Levodopa vs Placebo (Sonde & Lokk 2007). One RCT compared Methylphenidate vs Placebo with Levodopa vs Placebo (Lokk et al. 2011).

The methodological details and results of all ten RCTs are presented in Table 43.

Table 43. RCTs Evaluating Stimulants for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)
Amphetamines vs Placebo		
Goldstein et al. (2018) RCT (8) Nstart=64 Nend=59 TPS=Acute A vs 0	E: Dextroamphetamine + conventional therapy C: Placebo + conventional therapy Duration: 60min/d, q4d (6 sessions total) conventional therapy & 10mg/d, q4d (6 doses total) Dextroamphetamine/sham	E vs C: Fugl-Meyer motor score (-) Modified Rankin Scale (-) National Institutes of Health Stroke Scale (-) Canadian Neurological Scale (-) Action Research Arm Test (-) Functional Independence Measure (-) 6-minute walk test (-) Mini-Mental State Examination (-) Beck Depression Inventory (-) Stroke Impact Scale (-)
Gladstone et al. (2006) RCT (7) Nstart=71 Nend=67 TPS=Acute A vs 0	E: D-Amphetamine sulfate (10mg/d) + Physiotherapy C: Placebo + Physiotherapy Duration: 2d/wk, for 5wks	E vs C: Fugl-Meyer Assessment (-) Upper Extremity (-) Lower Extremity (-) Clinical Outcome Variable Scale Ambulation Performance (-) Independent Ambulation with Environmental Barriers (-) Functional Independence Measure (-) Modified Rankin Scale (-) Chedoke-McMaster Disability Inventory (-) Arm and Hand Activity (-)
Martinsson & Wahlgren (2003a) RCT (8) Nstart=45 Nend=38 TPS=Acute A1 vs A2 vs A3 vs 0	E1: Dexamphetamine (2.5mg) E2: Dexamphetamine (5.0mg) E3: Dexamphetamine (10mg) C: Placebo Duration: 1capsule 2x/d, for 5d	E1/E2/E3 vs C: Scandinavian Stroke Scale (+exp) Lindmark Motor Assessment (+exp) Activity Index (+exp) 10-Meter Walk Test (-) heart rate (+exp) BP (+exp)
Treig et al. (2003) RCT (9) Nstart=24 Nend=24 TPS=Acute A vs 0	E: D-Amphetamine (10mg/d) + Physiotherapy C: Placebo + Physiotherapy Duration: Every fourth day (10d total) for 36d Medication/placebo, 45min/d, 5d/wk, for 36d physiotherapy	E vs C: Rivermead Motor Assessment (-) Barthel Index (-)
Sonde et al. (2001) RCT (9) Nstart=40 Nend=40 TPS=Acute A vs 0	E: Amphetamine (10mg/d) + Physiotherapy + Regular training C: Placebo + Physiotherapy + Regular training Duration: 2d/wk, for 5wks Amphetamine/placebo, 30min/d, 5d/wk, for 5wks Physiotherapy	E vs C: Fugl-Meyer Assessment (-) Barthel Index (-)

Walker-Batson (1995) RCT (6) Nstart=10 Nend=10 TPS=Acute A vs 0	E: Dextroamphetamine (10mg/d) + physical therapy C: Placebo + physical therapy Duration: Every 4d for 10 sessions	E vs C: Fugl-Meyer Assessment (+exp)
Crisostomo et al. (1988) RCT (8) Nstart=8 Nend=8 TPS=Acute A vs 0	E: Amphetamine (10mg) + physiotherapy C: Placebo + physiotherapy Duration: Single dose injection & single 45min physiotherapy session	E vs C: Fugl-Meyer Assessment Upper Extremity (+exp) Lower Extremity (+exp)
Amphetamine with Intensive Physiotherapy vs Amphetamine with Conventional Physiotherapy		
Martinsson et al. (2003b) RCT (7) Nstart=30 Nend=28 TPS=Acute A + B vs A	E: Dexamphetamine (10mg, 2x/d) + Intensive physiotherapy C: Dexamphetamine (10mg, 2x/d) + Conventional physiotherapy Duration: 30-45min, 2x/d, for 5d Intensive physiotherapy & 15min/d, for 5d Standard physiotherapy	E vs C: Lindmark Motor Assessment Chart (-) Activity Index (-) National Institute of Health Stroke Scale (-)
Amphetamine vs Levodopa vs Placebo		
Sonde & Lokk (2007) RCT (7) Nstart=30 Nend=25 TPS=Acute A + B vs A vs B vs 0 Also in Table 44 (Dopamine Agonists)	E1: Amphetamine (10mg/d) + Levodopa (50mg/d) E2: Amphetamine (20mg/d) + Levodopa placebo E3: Amphetamine placebo + Levodopa (100mg/d) C: Amphetamine placebo + Levodopa placebo Duration: 5d/wk for 2wks	E1/E2/E3 vs C: Fugl-Meyer Assessment (-) Barthel Index (-)
Methylphenidate vs Levodopa vs Placebo		
Lokk et al. (2011) RCT (8) Nstart=100 Nend=78 TPS=Subacute A vs B vs A + B vs 0 Also in Table 44 (Dopamine Agonists)	E1: Methylphenidate (20mg/d) + conventional physiotherapy E2: Levodopa (125mg/d) + conventional physiotherapy E3: Methylphenidate + Levodopa + conventional physiotherapy C: Placebo + conventional physiotherapy Duration: 10mg, 2doses/d, 5d/wk, for 3wks (15 total sessions) & 45min/d, 5d/wk, for 3wks physiotherapy	E1 vs E2 vs E3 vs C: Barthel index (No stats) Fugl-Meyer Motor assessment (-) National Institute of Stroke Scale (No stats)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Amphetamines may not have a difference in efficacy when compared to Placebo for improving upper extremity function.	3	Goldstein et al. 2018; Gladstone et al. 2006; Crisostomo et al. 1988

Key Points

- Amphetamines may be beneficial for improving aerobic measures, but not motor recovery, activities of daily living, gait speed, gait endurance, functional mobility, and quality of life, after stroke when compared to Placebo.
- Amphetamine with Intensive Physiotherapy may not be beneficial for improving motor recovery after stroke when compared to Amphetamine with Conventional Physiotherapy.
- Amphetamine vs Placebo may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Levodopa or Placebo.
- Methylphenidate vs Placebo may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Levodopa or Placebo.

Summary of Key Points: Stimulants

Intervention	Control(s)	Function domain(s)	Effect
Amphetamines	Placebo	Aerobic measures	+
Amphetamines	Placebo	Motor recovery, activities of daily living, gait speed, gait endurance, functional mobility, quality of life	–

Amphetamine with Intensive Physiotherapy	Amphetamine with Conventional Physiotherapy	Motor recovery	–
Amphetamine vs Placebo	Levodopa vs Placebo	Motor recovery, activities of daily living	–
Methylphenidate vs Placebo	Levodopa vs Placebo	Motor recovery, activities of daily living	–

Dopamine Agonists

Adopted from: https://medium.com/parkinsons-uk/how-do-levodopa-medications-work-ac6a6e58e143

Dopamine agonists are effective at controlling motor symptoms in patients with Parkinson's disease, with Levodopa being the current gold standard treatment (Antonini, 2007). While levodopa is possibly the most potent of the Parkinsonian drugs, its prolonged use can cause a variety of side effects, thus dopamine agonists are also commonly used in therapy (Kulisevsky & Pagonabarraga, 2010). Dopamine agonists have shown the ability to delay the initiation of levodopa therapy and have even been shown to modify the course of certain motor complications associated with levodopa use, such as dyskinesia (Kulisevsky & Pagonabarraga, 2010). Ropinirole is one such dopamine agonist used in therapy.

A total of six RCTs were found that evaluated dopamine agonists for lower extremity motor rehabilitation. Three RCTs compared Levadopa or No Medication with Placebo or No Medication (Ford et al. 2019; Acler et al. 2009; Scheidtmann et al. 2001). Two RCTs evaluated Levodopa with Stimulants (Lokk et al. 2011; Sonde & Lokk 2007). One RCT compared Ropinirole with Placebo (Cramer et al. 2009).

In addition, two RCTs in which dopamine agonists formed part of a combined or comparative intervention are cross-referenced at the end of Table 44; their primary listings appear in other tables.

The methodological details and results of all six RCTs are presented in Table 44.

Table 44. RCTs Evaluating Dopamine Agonists for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**

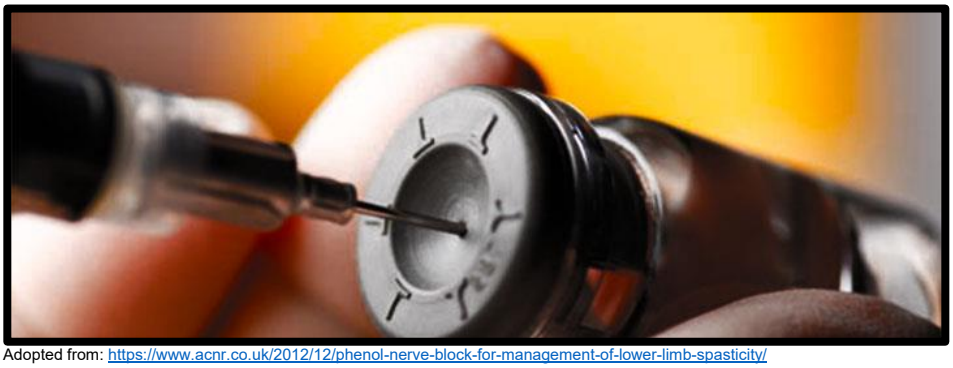
1b	Levadopa or No Medication may not have a difference in efficacy when compared to Placebo or No Medication for improving upper extremity function.	1	Ford et al. 2019
2	There is conflicting evidence about the effect of L-DOPA 100mg/d when compared to Placebo for improving upper extremity function.	1	Acler et al. 2009



Key Points

- Levadopa or No Medication may be beneficial for improving motor recovery, but not activities of daily living and gait speed, after stroke when compared to Placebo or No Medication; the literature is mixed regarding functional mobility and quality of life.
- L-DOPA 100mg/d may be beneficial for improving gait speed, but not motor recovery and neurophysiological measures, after stroke when compared to Placebo.
- Methylphenidate (20mg/d) with conventional physiotherapy may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Levadopa (125mg/d) with conventional physiotherapy or Methylphenidate, Levadopa and conventional physiotherapy.
- Amphetamine (10mg/d) with Levodopa (50mg/d) may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Amphetamine placebo with Levodopa placebo.
- Ropinirole may not be beneficial for improving motor recovery, activities of daily living, gait speed, gait endurance, and quality of life after stroke when compared to Placebo.

Summary of Key Points: Dopamine Agonists

Intervention	Control(s)	Function domain(s)	Effect
Levadopa or No Medication	Placebo or No Medication	Motor recovery	+
Levadopa or No Medication	Placebo or No Medication	Activities of daily living, gait speed	–
Levadopa or No Medication	Placebo or No Medication	Functional mobility, quality of life	=
Methylphenidate (20mg/d) with conventional physiotherapy	Levadopa (125mg/d) with conventional physiotherapy or Methylphenidate, Levadopa and conventional physiotherapy	Motor recovery, activities of daily living	–
Amphetamine (10mg/d) with Levodopa (50mg/d)	Amphetamine placebo with Levodopa placebo	Motor recovery, activities of daily living	–
Ropinirole	Placebo	Motor recovery, activities of daily living, gait speed, gait endurance, quality of life	–
L-DOPA 100mg/d	Placebo	Motor recovery, neurophysiological measures	–
L-DOPA 100mg/d	Placebo	Gait speed	+

Nerve Block Agents

Adopted from: https://www.acnr.co.uk/2012/12/phenol-nerve-block-for-management-of-lower-limb-spasticity/

Nerve blocks are a locally acting treatment for spasticity that have the advantage of reducing harmful spasticity in one area, while preserving useful spasticity in another area (Kirazli et al. 1998). Motor nerve blocks can be used to evaluate the potential role of muscle overactivity in abnormal movements. Depending on the pharmacological agent used, the temporary effect of a nerve block reverses within 1–12 h (Gross et al., 2014). Phenol is a commonly used nerve block agent that denatures protein and causes generalized neurolysis that affects both motor and sensory nerve fibers, thus reducing muscle tone by reducing abnormal neural signals. Phenol is effective in spasticity of large proximal leg muscles or as a nerve block in spastic foot drop (Fu et al., 2013). Radiofrequency thermocoagulation is another nerve block agent in which nerve fibres are blocked via thermal damage (Shen et al., 2017).

A total of four RCTs were found that evaluated nerve block agents for lower extremity motor rehabilitation. One RCT compared Botulinum Toxin with Phenol (Kirazli et al. 1998). One RCT compared Nerve block with Phenol with Ethyl Alcohol (Kocabas et al. 2010). One RCT evaluated Nerve Block with AFO Device (Beckerman et al. 1996a). One RCT compared Curare Medications with Homeopathic Medications (Pramanick et al. 2020).

The methodological details and results of all four RCTs are presented in Table 45.

Table 45. RCTs Evaluating Nerve Block Agents for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Botulinum Toxin vs Phenol		
Kirazli et al. (1998) RCT (8) Nstart=20 Nend=20 TPS=Chronic A vs B Also in Table 46 (Botulinum Toxin)	E1: Botulinum Toxin A (400 U) E2: Tibial nerve blockade (Phenol) Duration: One session	E1 vs E2: Active ROM (No stats) Passive ROM (No stats) Brace Wear Scale (-) Ashworth Scale (+exp1) 25 feet walk test (+exp) Global Assessment of Spasticity Scale (+exp1) Clonus duration (by EMG) (+exp)
Nerve block with Phenol vs Ethyl Alcohol		
Kocabas et al. (2010) RCT (5) Nstart=20 Nend=20 TPS=Chronic A vs B	E1: 50% Ethyl alcohol injection (5mL) E2: 5% Phenol injection (5mL) Duration: single treatment	E1 vs E2: Modified Ashworth Scale (-) Passive Range of Motion (-) Ankle clonus (-) Medical Research Council ankle strength (-)

Nerve Block with AFO Device		
Beckerman et al. (1996a) RCT (7) Nstart=60 Nend=58 TPS=Chronic A + B vs B vs A vs 0 Also in Table 13 (Orthotic Devices)	E1: Tibial nerve block through thermocoagulation + AFO E2: Sham thermocoagulation + AFO E3: Thermocoagulation + Sham AFO E4: Sham thermocoagulation + Sham AFO Duration: 45-60min/1session thermocoagulation	E1/E3 vs E2/E4: Modified Ashworth Scale (-) Ankle Clonus Score (+exp1, +exp3) Achilles tendon reflex (+exp1, +exp3) Fugl-Meyer Assessment (-) Spasticity (+exp1, +exp3) Sickness Impact Profile (-) Walking Speed (-)
Curare vs Homeopathic Medications		
Pramanick et al. (2020) RCT (6) Nstart=50 Nend=45 TPS=Chronic A vs B	E: Curare 30CH + Conventional therapy C: Individualized homeopathic medicines + Conventional therapy Duration: Each dose=4 globules of medicine. Individualized dosage for each person.	E vs C: Oxford Muscle scale-strength grading (-) Stroke Impact scale Physical Problems (-) Memory And Thinking (-) Mood And Emotion (-) Communication And Understanding (-) Usual Activities (-) Mobility (-) Ability To Use Affected Hand (-) Stroke Affected Ability to Participate in Social Activities (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Tibial nerve block through thermocoagulation with ankle-foot orthosis may not have a difference in efficacy when compared to Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis for improving motor recovery.	1	Beckerman et al. 1996a

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Tibial nerve block through thermocoagulation with ankle-foot orthosis may not have a difference in efficacy when compared to Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis for improving quality of life.	1	Beckerman et al. 1996a
1b	Curare Medications may not have a difference in efficacy when compared to Homeopathic Medications for improving quality of life.	1	Pramanick et al. 2020

Key Points

- Botulinum Toxin A (400 U) may be beneficial for improving spasticity, but not range of motion, after stroke when compared to Tibial nerve blockade (Phenol).

- 50% Ethyl alcohol injection (5mL) may not be beneficial for improving muscle strength, spasticity, and range of motion after stroke when compared to 5% Phenol injection (5mL).
- Tibial nerve block through thermocoagulation with ankle-foot orthosis may not be beneficial for improving motor recovery, spasticity, gait speed, and quality of life after stroke when compared to Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis.
- Curare Medications may not be beneficial for improving muscle strength and quality of life after stroke when compared to Homeopathic Medications.

Summary of Key Points: Nerve Block Agents

Intervention	Control(s)	Function domain(s)	Effect
Botulinum Toxin A (400 U)	Tibial nerve blockade (Phenol)	Spasticity	+
Botulinum Toxin A (400 U)	Tibial nerve blockade (Phenol)	Range of motion	–
50% Ethyl alcohol injection (5mL)	5% Phenol injection (5mL)	Muscle strength, spasticity, range of motion	–
Tibial nerve block through thermocoagulation with ankle-foot orthosis	Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis	Motor recovery, spasticity, gait speed, quality of life	–
Curare Medications	Homeopathic Medications	Muscle strength, quality of life	–

Botulinum Toxin

Adopted from: https://www.pointperformance.com/managing-pain-with-botox/

Botulinum toxin is a pharmacological agent, administered through injections, which reduces muscle tone and overactivity in spastic muscles. It exerts a therapeutic effect by presynaptically blocking the release of acetylcholine at the neuromuscular junction. The benefits of botulinum toxin injections are generally dose-dependent and last approximately 2 to 4 months before nerve resprouting reverses the functional blockade (Brashear et al., 2002; Francisco et al., 2002; Pandyan et al., 2002; Simpson et al., 1996; Smith et al., 2000). One of the advantages of

botulinum toxin is that it reduces spasticity only in the injected muscles as opposed to other systemic treatments, which can have more widespread antispastic effects (Pandyan et al., 2002). Unlike chemodenervation and neurolytic procedures like phenol or alcohol, botulinum toxin is not associated with skin sensory loss, dysesthesia, or other side effects like fatigue and weakness (Pandyan et al., 2002; Suputtitada & Suwanwela, 2005). The most widely used type of botulinum toxin is botulinum toxin A, which has two further variations known as abobotulinum toxin A and onabotulinum toxin A. Both types share the same pharmacology and are used for similar purposes, however they differ with respect to their unit potency and nontoxin protein content, making their pharmacodynamic properties unique (Nestor & Ablon, 2011). Dynamic EMG studies can be helpful in determining which muscles should be injected (Bell & Williams, 2003).

A total of 46 RCTs were found that evaluated botulinum toxin for lower extremity motor rehabilitation. Twelve RCTs compared Botulinum Toxin A with Placebo (Tenniglo et al. 2023; Masakado et al. 2021; Kerzoncuf et al. 2020; Patel et al. 2020; Esquenazi et al. 2019; Prazeres et al. 2018; Wein et al. 2018; Tao et al. 2015; Fietzek et al. 2014; Ward et al. 2014; Kaji et al. 2010; Burbaud et al. 1996). Two RCTs evaluated Botulinum Toxin A with Ankle-foot Orthosis (Ding et al. 2015; Farina et al. 2008). Three RCTs evaluated Botulinum Toxin A with Casting or Taping (Carda et al. 2011; Karadag-Saygi et al. 2010; Reiter et al. 1998). Two RCTs evaluated Botulinum Toxin A with Electrical Stimulation (Baricich et al. 2019; Lannin et al. 2018). Three RCTs evaluated Botulinum Toxin A with FES (Ding et al. 2017; Baricich et al. 2008; Johnson et al. 2004). Two RCTs evaluated Botulinum Toxin A with TENS (Picelli et al. 2014; Bayram et al. 2006). One RCT compared Botox with Neurotomy (Bollens et al. 2013). One RCT compared Botox with Phenol (Kirazli et al. 1998). Two RCTs evaluated Location of Injection (Im et al. 2014; Childers et al. 1996). Six RCTs evaluated Dosage of Injection (Gracies et al. 2017; Li et al. 2017; Pimentel et al. 2014; Dunne et al. 2012; Mancini et al. 2005; Pittock et al. 2003). Two RCTs evaluated Method of Injection Guidance (Turna et al. 2020; Picelli et al. 2012b). One RCT evaluated Botulinum Toxin with Task-Oriented Rehabilitation (Roche et al. 2015). Three RCTs compared Botox Combined with Robotics with Botox and Conventional Therapy (Cotinat et al. 2024; Erbil et al. 2018; Picelli et al. 2016). One RCT compared Botulinum Toxin A + EMG Biofeedback Treatment + Conventional Care with Botulinum Toxin A + Conventional Care (Chen et al. 2015b). One RCT compared Forward Treadmill Training with Botulinum Toxin with Backward Treadmill Training with Botulinum Toxin (Munari et al. 2020). One RCT compared Botulinum Toxin A with Conventional Therapy (Yu et al. 2023).

In addition, two RCTs in which botulinum toxin formed part of a combined or comparative intervention are cross-referenced at the end of Table 46; their primary listings appear in other tables.

The methodological details and results of all 46 RCTs are presented in Table 46.

Botulinum Toxin A + EMG Biofeedback Treatment + Conventional Care vs Botulinum Toxin A + Conventional Care		
Chen et al. (2015b) RCT (4) Nstart=36 Nend=36 TPS=Subacute A + B vs A Also in Table 15 (Biofeedback)	E: Botulinum Toxin A injection (under ultrasound guidance) + EMG biofeedback treatment + conventional care C: Botulinum Toxin A injection (under ultrasound guidance) + conventional care Duration: 20min/d, 5d/wk, for 6wks biofeedback & single session botulinum toxin-A nerve block	E vs C: Modified Ashworth Scale (No stats) Step Length (No stats) Walking Speed (No stats)
Forward vs Backward Treadmill Training with Botulinum Toxin		
Munari et al. (2020) RCT (8) Nstart=18 Nend=18 TPS=Chronic A + B vs B Also in Table 9 (Treadmill Training)	E: Backward treadmill training + botulinum toxin type A therapy C: Standard forward treadmill training + botulinum toxin type A therapy Duration: 40min/d, 3d/wk, for 4wks	E vs C: 10-meter walking test (+exp1) Modified Ashworth scale (-) Gait analysis Step length (-) Stride length (-) Cadence (-) Stabilometric assessment length CoP eyes open (+exp1) sway area eyes open (+exp1) length CoP eyes closed (+exp1) sway area eyes closed (+exp1)

Botulinum Toxin A vs Conventional Therapy		
Yu et al. (2023) RCT (3) Nstart=46 Nend=43 TPS=Subacute A vs 0	E: BoNT-A Injection + Routine rehabilitation C: Routine rehabilitation Duration: 1x injection; rehab: 60min/d, 5d/wk, 12wks	E vs C: FMA-LE (+exp) TUG (+exp) stride length (+exp) 10MWT (+exp) pressure forefoot (+exp) rearfoot (-) mAS (no stat)
Additional Comparisons from the Source Dataset		
Cinone et al. (2019) RCT (6) Nstart=25 Nend=25 TPS=Chronic A + B vs X	E: Botulinum Toxin A (50-100U) + Isokinetic training C: Botulinum Toxin A (50-100U) Duration: Single time injection BTA & 50min/session, 5x/wk for 4wks	E vs C: Modified Ashworth scale (No stats) Motricity index (No stats) Modified Tardieu Scale (No stats) 6min Walk Test (No stats) 10m Walk test (No stats) Cadence (No stats) Step length (No stats) Single support phase (No stats)
McAllister et al. (2019) RCT (6) Nstart=127 Nend=127 TPS=Chronic A1 vs A2	E1: Received co-injection of abobotulinumtoxinA (aboBoNT-A) in both the upper and lower limbs during treatment cycle 3 and 4 E2: Received injection of aboBoNT-A in the lower limb only at treatment cycle 3 and 4 C: 1000-1500 U total botulinum toxin lower limb + upper limb injection Duration: Injection(s) at treatment cycle 3 and 4 with minimum 12wks between	E vs C: 10m walk test (-)
Johnson et al. (2002) RCT (4) Nstart=21 Nend=18 TPS=Subacute A + B vs X	E: botulinum neurotoxin Type A + functional electrical stimulation + conventional physiotherapy C: Conventional physiotherapy Duration: 600U Botox 1 time (200 U of Dysport and the tibialis posterior with 400 U) 1 time FES duration not specified, after botox 1/d, 2-3d/wk, 12 wks physiotherapy	E vs C: 10m Walking speed (No stats) Physiological cost index (No stats)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Munari et al. (2020) RCT (8) Nstart=18 Nend=18 TPS=Chronic A + B vs B Primary listing: Table 9 (Treadmill Training)	E: Backward treadmill training + botulinum toxin type A therapy C: Standard forward treadmill training + botulinum toxin type A therapy Duration: 40min/d, 3d/wk, for 4wks	E vs C: 10-meter walking test (+exp1) Modified Ashworth scale (-) Step length (-) Stride length (-) Cadence (-) Stabilometric assessment Length CoP eyes open (+exp1) Sway area eyes open (+exp1) Length CoP eyes closed (+exp1) Sway area eyes closed (+exp1)
Kirazli et al. (1998) RCT (8)	E1: Botulinum Toxin A (400 U) E2: Tibial nerve blockade (Phenol)	E1 vs E2: Active ROM (No stats)

Nstart=20 Nend=20 TPS=Chronic A vs B Primary listing: Table 45 (Nerve Block Agents)	Duration: One session	Passive ROM (No stats) Brace Wear Scale (-) Ashworth Scale (+exp1) 25 feet walk test (+exp) Global Assessment of Spasticity Scale (+exp1) Clonus duration (by EMG) (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Botulinum Toxin A when compared to Placebo for improving motor recovery.	3	Prazeres et al. 2018; Tao et al. 2015; Burbaud et al. 1996
2	There is conflicting evidence about the effect of Botulinum Toxin A with Ankle-foot Orthosis when compared to Conventional rehabilitation for improving motor recovery.	1	Ding et al. 2015
1a	There is conflicting evidence about the effect of Botulinum Toxin A with functional electrical stimulation when compared to Botulinum toxin A injection for improving motor recovery.	2	Ding et al. 2017; Johnson et al. 2004
1b	Botulinum toxin A (100U) in mid belly of the gastrocnemius with placebo injected in distal of popliteal fossa may not have a difference in efficacy when compared to Botulinum toxin A (100U) at distal to the popliteal fossa with placebo injected in mid belly for improving motor recovery.	1	Childers et al. 1996
1b	Dosage of Injection may not have a difference in efficacy when compared to Placebo for improving motor recovery.	1	Pittock et al. 2003
2	Ultrasonography guided Botulinum toxin A (1000U) may not have a difference in efficacy when compared to Electrical stimulation guided Botulinum toxin A (1000U) for improving motor recovery.	1	Turna et al. 2020
2	Botulinum Toxin A may produce greater improvements in motor recovery than Conventional Therapy.	1	Yu et al. 2023

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Botulinum Toxin A may produce greater improvements in biomechanical gait measures than Placebo.	1	Tao et al. 2015
2	Botulinum toxin A (190-320U) with ankle-foot orthosis may produce greater improvements in biomechanical gait measures than Botulinum toxin A (190-320U).	1	Farina et al. 2008
2	Botulinum toxin A (100U) injection into tibialis posterior with ankle-foot adhesive taping may not have a difference in efficacy when compared to electromyography-guided Botulinum toxin A (190-320U) injection into several calf muscles for improving biomechanical gait measures.	1	Reiter et al. 1998

1b	Botulinum toxin A (500U) with functional electrical stimulation may not have a difference in efficacy when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching for improving biomechanical gait measures.	1	Baricich et al. 2008
1b	Botulinum toxin (200U) may not have a difference in efficacy when compared to Neurotomy for improving biomechanical gait measures.	1	Bollens et al. 2013
1b	Dosage of Injection may not have a difference in efficacy when compared to Placebo for improving biomechanical gait measures.	1	Pittock et al. 2003
2	Botulinum Toxin A with electromyography Biofeedback Treatment and Conventional Care may not have a difference in efficacy when compared to Botulinum Toxin A with Conventional Care for improving biomechanical gait measures.	1	Chen et al. 2015b
1b	Forward Treadmill Training with Botulinum Toxin may not have a difference in efficacy when compared to Backward Treadmill Training with Botulinum Toxin for improving biomechanical gait measures.	1	Munari et al. 2020
2	Botulinum Toxin A may produce greater improvements in biomechanical gait measures than Conventional Therapy.	1	Yu et al. 2023
1b	Botulinum Toxin A (50-100U) + Isokinetic training may not have a difference in efficacy when compared to Botulinum Toxin A (50-100U) for improving biomechanical gait measures.	1	Cinone et al. 2019
1b	Backward treadmill training with botulinum toxin type A therapy may not have a difference in efficacy when compared to forward treadmill training with botulinum toxin type A therapy for improving biomechanical gait measures.	1	Munari et al. 2020

BIOMECHANICAL BALANCE MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Botulinum Toxin A may not have a difference in efficacy when compared to Placebo for improving biomechanical balance measures.	1	Kerzoncuf et al. 2020
1b	Forward Treadmill Training with Botulinum Toxin may produce greater improvements in biomechanical balance measures than Backward Treadmill Training with Botulinum Toxin.	1	Munari et al. 2020
1b	Backward treadmill training with botulinum toxin type A therapy may produce greater improvements in biomechanical balance measures than forward treadmill training with botulinum toxin type A therapy.	1	Munari et al. 2020

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Botulinum Toxin A may not have a difference in efficacy when compared to Placebo for improving muscle strength.	1	Tenniglo et al. 2023
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may not have a difference in efficacy when compared to Botulinum toxin A (100U) with Taping and stretching and gait training for improving muscle strength.	1	Carda et al. 2011
1b	Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not have a difference in efficacy when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles for improving muscle strength.	1	Baricich et al. 2019

1b	Botulinum Toxin A (50-100U) + Isokinetic training may not have a difference in efficacy when compared to Botulinum Toxin A (50-100U) for improving muscle strength.	1	Cinone et al. 2019

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Botulinum Toxin A may produce greater improvements in spasticity than Placebo.	9	Masakado et al. 2021; Kerzoncuf et al. 2020; Patel et al. 2020; Esquenazi et al. 2019; Wein et al. 2018; Tao et al. 2015; Fietzek et al. 2014; Kaji et al. 2010; Burbaud et al. 1996
2	There is conflicting evidence about the effect of Botulinum Toxin A with Ankle-foot Orthosis when compared to Conventional rehabilitation for improving spasticity.	1	Ding et al. 2015
2	Botulinum toxin A (190-320U) with ankle-foot orthosis may produce greater improvements in spasticity than Botulinum toxin A (190-320U).	1	Farina et al. 2008
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may produce greater improvements in spasticity than Botulinum toxin A (100U) with Taping and stretching and gait training.	1	Carda et al. 2011
1b	Botulinum Toxin A with Casting or Taping may not have a difference in efficacy when compared to Botulinum toxin A (75- 100U) with Sham taping and home exercises for improving spasticity.	1	Karadag-Saygi et al. 2010
2	Botulinum toxin A (100U) injection into tibialis posterior with ankle-foot adhesive taping may not have a difference in efficacy when compared to electromyography-guided Botulinum toxin A (190-320U) injection into several calf muscles for improving spasticity.	1	Reiter et al. 1998
1b	Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not have a difference in efficacy when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles for improving spasticity.	1	Baricich et al. 2019
1b	Botulinum Toxin A with Electrical Stimulation may not have a difference in efficacy when compared to Botox Injections (50U-120U) with neuromuscular electrical stimulation of Injected Agonist Muscles for improving spasticity.	1	Lannin et al. 2018
1a	There is conflicting evidence about the effect of Botulinum Toxin A with functional electrical stimulation when compared to Botulinum toxin A injection for improving spasticity.	2	Ding et al. 2017; Johnson et al. 2004
1b	Botulinum toxin A (500U) with functional electrical stimulation may not have a difference in efficacy when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching for improving spasticity.	1	Baricich et al. 2008
1b	Therapeutic ultrasound with Home exercises & conventional therapy may not have a difference in efficacy when compared to transcutaneous electrical nerve stimulation with Home exercises & conventional therapy for improving spasticity.	1	Picelli et al. 2014
1b	Therapeutic ultrasound with Home exercises & conventional therapy may result in lesser improvements in spasticity when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.	1	Picelli et al. 2014
1b	Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy may result in lesser improvements in spasticity	1	Picelli et al. 2014

	when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.		
2	Botulinum Toxin A with transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to High-dose Botulinum toxin (400U) with Sham electrical stimulation for improving spasticity.	1	Bayram et al. 2006
1b	Botulinum toxin (200U) may produce greater improvements in spasticity than Neurotomy.	1	Bollens et al. 2013
1b	Botulinum Toxin A (400 U) may produce greater improvements in spasticity than Phenol.	1	Kirazli et al. 1998
1b	Location of Injection may not have a difference in efficacy when compared to Distal gastrocnemius Botulinum toxin A injection 200U for improving spasticity.	1	Im et al. 2014
1b	Botulinum toxin A (100U) in mid belly of the gastrocnemius with placebo injected in distal of popliteal fossa may not have a difference in efficacy when compared to Botulinum toxin A (100U) at distal to the popliteal fossa with placebo injected in mid belly for improving spasticity.	1	Childers et al. 1996
1b	There is conflicting evidence about the effect of Dosage of Injection when compared to Placebo for improving spasticity.	1	Gracies et al. 2017
1b	There is conflicting evidence about the effect of Low-dose/low-concentration Botulinum toxin A when compared to Low-dose/high-concentration botulinum toxin A or High-dose/low- concentration botulinum toxin A or High-dose/high- concentration botulinum toxin A for improving spasticity.	1	Li et al. 2017
1b	Botulinum toxin A with Conventional Therapy (300U) may produce greater improvements in spasticity than Botulinum toxin A with Conventional Therapy (100U).	1	Pimentel et al. 2014
1b	OnabotulinumtoxinA (200U) may not have a difference in efficacy when compared to OnabotulinumtoxinA (300U) for improving spasticity.	1	Dunne et al. 2012
1b	Botulinum toxin A (167U) may result in lesser improvements in spasticity when compared to Botulinum toxin A (322U).	1	Mancini et al. 2005
1b	Botulinum toxin A (167U) may result in lesser improvements in spasticity when compared to Botulinum toxin A (540U).	1	Mancini et al. 2005
1b	Botulinum toxin A (322U) may not have a difference in efficacy when compared to Botulinum toxin A (540U) for improving spasticity.	1	Mancini et al. 2005
2	Ultrasonography guided Botulinum toxin A (1000U) may not have a difference in efficacy when compared to Electrical stimulation guided Botulinum toxin A (1000U) for improving spasticity.	1	Turna et al. 2020
1b	Botulinum toxin A (200U) by ultrasonography may not have a difference in efficacy when compared to Botulinum toxin A (200U) by electrical stimulation for improving spasticity.	1	Picelli et al. 2012b
1b	Botulinum toxin A (200U) by ultrasonography may not have a difference in efficacy when compared to Botulinum toxin A (200U) by palpation for improving spasticity.	1	Picelli et al. 2012b
1b	Botulinum toxin A (200U) by electrical stimulation may not have a difference in efficacy when compared to Botulinum toxin A (200U) by palpation for improving spasticity.	1	Picelli et al. 2012b
2	Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may not have a difference in efficacy when compared to Botulinum Toxin A Injection for improving spasticity.	1	Roche et al. 2015

1a	Botox Combined with Robotics may not have a difference in efficacy when compared to Botox and Conventional Therapy for improving spasticity.	3	Cotinat et al. 2024; Erbil et al. 2018; Picelli et al. 2016

1b	Botulinum toxin (200U) may not have a difference in efficacy when compared to Neurotomy for improving range of motion.	1	Bollens et al. 2013
1b	Botulinum Toxin A (400 U) may not have a difference in efficacy when compared to Phenol for improving range of motion.	1	Kirazli et al. 1998
1b	Location of Injection may not have a difference in efficacy when compared to Distal gastrocnemius Botulinum toxin A injection 200U for improving range of motion.	1	Im et al. 2014
1b	Botulinum toxin A (100U) in mid belly of the gastrocnemius with placebo injected in distal of popliteal fossa may not have a difference in efficacy when compared to Botulinum toxin A (100U) at distal to the popliteal fossa with placebo injected in mid belly for improving range of motion.	1	Childers et al. 1996
1b	There is conflicting evidence about the effect of OnabotulinumtoxinA (200U) when compared to OnabotulinumtoxinA (300U) for improving range of motion.	1	Dunne et al. 2012
1b	Dosage of Injection may not have a difference in efficacy when compared to Placebo for improving range of motion.	1	Pittock et al. 2003
1b	Botulinum toxin A (200U) by ultrasonography may not have a difference in efficacy when compared to Botulinum toxin A (200U) by electrical stimulation for improving range of motion.	1	Picelli et al. 2012b
1b	Botulinum toxin A (200U) by ultrasonography may result in lesser improvements in range of motion when compared to Botulinum toxin A (200U) by palpation.	1	Picelli et al. 2012b
1b	Botulinum toxin A (200U) by electrical stimulation may result in lesser improvements in range of motion when compared to Botulinum toxin A (200U) by palpation.	1	Picelli et al. 2012b
2	Botox Combined with Robotics may not have a difference in efficacy when compared to Botox and Conventional Therapy for improving range of motion.	1	Erbil et al. 2018

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**

AEROBIC MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Botulinum Toxin A may not have a difference in efficacy when compared to Placebo for improving aerobic measures.	1	Tenniglo et al. 2023
1b	Botulinum Toxin A with functional electrical stimulation may produce greater improvements in aerobic measures than Botulinum toxin A injection.	1	Johnson et al. 2004
2	Botulinum neurotoxin Type A with functional electrical stimulation and conventional physiotherapy may not have a difference in efficacy when compared to Conventional physiotherapy for improving aerobic measures.	1	Johnson et al. 2002

PAIN			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Botulinum Toxin A may not have a difference in efficacy when compared to Placebo for improving pain.	1	Wein et al. 2018
1b	There is conflicting evidence about the effect of OnabotulinumtoxinA (200U) when compared to OnabotulinumtoxinA (300U) for improving pain.	1	Dunne et al. 2012
1b	Botulinum toxin A (167U) may not have a difference in efficacy when compared to Botulinum toxin A (322U) for improving pain.	1	Mancini et al. 2005
1b	Botulinum toxin A (167U) may not have a difference in efficacy when compared to Botulinum toxin A (540U) for improving pain.	1	Mancini et al. 2005
1b	Botulinum toxin A (322U) may not have a difference in efficacy when compared to Botulinum toxin A (540U) for improving pain.	1	Mancini et al. 2005
1b	Dosage of Injection may not have a difference in efficacy when compared to Placebo for improving pain.	1	Pittock et al. 2003

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Botulinum Toxin A may not have a difference in efficacy when compared to Placebo for improving activities of daily living.	6	Kerzoncuf et al. 2020; Patel et al. 2020; Esquenazi et al. 2019; Wein et al. 2018; Tao et al. 2015; Ward et al. 2014
2	There is conflicting evidence about the effect of Botulinum Toxin A with Ankle-foot Orthosis when compared to Conventional rehabilitation for improving activities of daily living.	1	Ding et al. 2015
1b	Botulinum Toxin A with Electrical Stimulation may not have a difference in efficacy when compared to Botox Injections (50U-120U) with neuromuscular electrical stimulation of Injected Agonist Muscles for improving activities of daily living.	1	Lannin et al. 2018
1b	Botulinum Toxin A with functional electrical stimulation may produce greater improvements in activities of daily living than Botulinum toxin A injection.	1	Ding et al. 2017
1b	Botulinum toxin A with Conventional Therapy (300U) may not have a difference in efficacy when compared to Botulinum toxin A with Conventional Therapy (100U) for improving activities of daily living.	1	Pimentel et al. 2014
2	Ultrasonography guided Botulinum toxin A (1000U) may not have a difference in efficacy when compared to Electrical stimulation guided Botulinum toxin A (1000U) for improving activities of daily living.	1	Turna et al. 2020

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Botulinum Toxin A may not have a difference in efficacy when compared to Placebo for improving gait speed.	8	Tenniglo et al. 2023; Masakado et al. 2021; Kerzoncuf et al. 2020; Patel et al. 2020; Wein et al. 2018; Tao et al. 2015; Kaji et al. 2010; Burbaud et al. 1996
2	Botulinum toxin A (190-320U) with ankle-foot orthosis may not have a difference in efficacy when compared to Botulinum toxin A (190-320U) for improving gait speed.	1	Farina et al. 2008

1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may not have a difference in efficacy when compared to Botulinum toxin A (100U) with Taping and stretching and gait training for improving gait speed.	1	Carda et al. 2011
1b	Botulinum Toxin A with Casting or Taping may not have a difference in efficacy when compared to Botulinum toxin A (75- 100U) with Sham taping and home exercises for improving gait speed.	1	Karadag-Saygi et al. 2010
2	Botulinum toxin A (100U) injection into tibialis posterior with ankle-foot adhesive taping may not have a difference in efficacy when compared to electromyography-guided Botulinum toxin A (190-320U) injection into several calf muscles for improving gait speed.	1	Reiter et al. 1998
1b	Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not have a difference in efficacy when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles for improving gait speed.	1	Baricich et al. 2019
1a	Botulinum Toxin A with functional electrical stimulation may produce greater improvements in gait speed than Botulinum toxin A injection.	2	Ding et al. 2017; Johnson et al. 2004
2	Botulinum Toxin A with transcutaneous electrical nerve stimulation may not have a difference in efficacy when compared to High-dose Botulinum toxin (400U) with Sham electrical stimulation for improving gait speed.	1	Bayram et al. 2006
1b	Botulinum toxin (200U) may not have a difference in efficacy when compared to Neurotomy for improving gait speed.	1	Bollens et al. 2013
1b	Location of Injection may not have a difference in efficacy when compared to Distal gastrocnemius Botulinum toxin A injection 200U for improving gait speed.	1	Im et al. 2014
1b	Botulinum toxin A (100U) in mid belly of the gastrocnemius with placebo injected in distal of popliteal fossa may not have a difference in efficacy when compared to Botulinum toxin A (100U) at distal to the popliteal fossa with placebo injected in mid belly for improving gait speed.	1	Childers et al. 1996
1b	Low-dose/low- concentration Botulinum toxin A may not have a difference in efficacy when compared to Low-dose/high-concentration botulinum toxin A or High-dose/low- concentration botulinum toxin A or High-dose/high- concentration botulinum toxin A for improving gait speed.	1	Li et al. 2017
1b	Botulinum toxin A with Conventional Therapy (300U) may not have a difference in efficacy when compared to Botulinum toxin A with Conventional Therapy (100U) for improving gait speed.	1	Pimentel et al. 2014
1b	Botulinum toxin A (167U) may result in lesser improvements in gait speed when compared to Botulinum toxin A (322U).	1	Mancini et al. 2005
1b	There is conflicting evidence about the effect of Botulinum toxin A (167U) when compared to Botulinum toxin A (540U) for improving gait speed.	1	Mancini et al. 2005
1b	There is conflicting evidence about the effect of Botulinum toxin A (322U) when compared to Botulinum toxin A (540U) for improving gait speed.	1	Mancini et al. 2005
2	Ultrasonography guided Botulinum toxin A (1000U) may not have a difference in efficacy when compared to Electrical stimulation guided Botulinum toxin A (1000U) for improving gait speed.	1	Turna et al. 2020
2	Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may produce greater improvements in gait speed than Botulinum Toxin A Injection.	1	Roche et al. 2015

1b	Botox Combined with Robotics may produce greater improvements in gait speed than Botox and Conventional Therapy.	1	Cotinat et al. 2024
2	Botulinum Toxin A with electromyography Biofeedback Treatment and Conventional Care may not have a difference in efficacy when compared to Botulinum Toxin A with Conventional Care for improving gait speed.	1	Chen et al. 2015b
1b	Forward Treadmill Training with Botulinum Toxin may produce greater improvements in gait speed than Backward Treadmill Training with Botulinum Toxin.	1	Munari et al. 2020
2	Botulinum Toxin A may produce greater improvements in gait speed than Conventional Therapy.	1	Yu et al. 2023
1b	Botulinum Toxin A (50-100U) + Isokinetic training may not have a difference in efficacy when compared to Botulinum Toxin A (50-100U) for improving gait speed.	1	Cinone et al. 2019
1b	Received co-injection of abobotulinumtoxinA (aboBoNT-A) in both the upper and lower limbs during treatment cycle 3 and 4 may not have a difference in efficacy when compared to 1000-1500 U total botulinum toxin lower limb with upper limb injection for improving gait speed.	1	McAllister et al. 2019
2	Botulinum neurotoxin Type A with functional electrical stimulation and conventional physiotherapy may not have a difference in efficacy when compared to Conventional physiotherapy for improving gait speed.	1	Johnson et al. 2002
1b	Backward treadmill training with botulinum toxin type A therapy may produce greater improvements in gait speed than forward treadmill training with botulinum toxin type A therapy.	1	Munari et al. 2020

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Botulinum Toxin A may produce greater improvements in gait endurance than Placebo.	3	Tenniglo et al. 2023; Prazeres et al. 2018; Tao et al. 2015
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may not have a difference in efficacy when compared to Botulinum toxin A (100U) with Taping and stretching and gait training for improving gait endurance.	1	Carda et al. 2011
1b	Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not have a difference in efficacy when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles for improving gait endurance.	1	Baricich et al. 2019
1b	Botulinum Toxin A with Electrical Stimulation may not have a difference in efficacy when compared to Botox Injections (50U-120U) with neuromuscular electrical stimulation of Injected Agonist Muscles for improving gait endurance.	1	Lannin et al. 2018
1b	Dosage of Injection may not have a difference in efficacy when compared to Placebo for improving gait endurance.	1	Pittock et al. 2003
2	Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may not have a difference in efficacy when compared to Botulinum Toxin A Injection for improving gait endurance.	1	Roche et al. 2015
1a	Botox Combined with Robotics may produce greater improvements in gait endurance than Botox and Conventional Therapy.	2	Cotinat et al. 2024; Picelli et al. 2016

1b	Botulinum Toxin A (50-100U) + Isokinetic training may not have a difference in efficacy when compared to Botulinum Toxin A (50-100U) for improving gait endurance.	1	Cinone et al. 2019

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Botulinum Toxin A may not have a difference in efficacy when compared to Placebo for improving functional mobility.	4	Tenniglo et al. 2023; Kerzoncuf et al. 2020; Prazeres et al. 2018; Kaji et al. 2010
1b	Botulinum toxin A (100U) with Serial casting and stretching and gait training may not have a difference in efficacy when compared to Botulinum toxin A (100U) with Taping and stretching and gait training for improving functional mobility.	1	Carda et al. 2011
1b	Botulinum toxin (200U) may not have a difference in efficacy when compared to Neurotomy for improving functional mobility.	1	Bollens et al. 2013
1b	Location of Injection may not have a difference in efficacy when compared to Distal gastrocnemius Botulinum toxin A injection 200U for improving functional mobility.	1	Im et al. 2014
1b	There is conflicting evidence about the effect of Low-dose/low-concentration Botulinum toxin A when compared to Low-dose/high-concentration botulinum toxin A or High-dose/low- concentration botulinum toxin A or High-dose/high- concentration botulinum toxin A for improving functional mobility.	1	Li et al. 2017
1b	There is conflicting evidence about the effect of OnabotulinumtoxinA (200U) when compared to OnabotulinumtoxinA (300U) for improving functional mobility.	1	Dunne et al. 2012
2	Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may not have a difference in efficacy when compared to Botulinum Toxin A Injection for improving functional mobility.	1	Roche et al. 2015
1b	Botox Combined with Robotics may produce greater improvements in functional mobility than Botox and Conventional Therapy.	2	Cotinat et al. 2024; Erbil et al. 2018
2	Botulinum Toxin A may produce greater improvements in functional mobility than Conventional Therapy.	1	Yu et al. 2023

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	There is conflicting evidence about the effect of Botulinum Toxin A with Ankle-foot Orthosis when compared to Conventional rehabilitation for improving balance.	1	Ding et al. 2015
1b	There is conflicting evidence about the effect of Botox Combined with Robotics when compared to Botox and Conventional Therapy for improving balance.	2	Cotinat et al. 2024; Erbil et al. 2018

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Botulinum Toxin A may produce greater improvements in quality of life than Placebo.	3	Tenniglo et al. 2023; Patel et al. 2020; Wein et al. 2018

1b	Botulinum Toxin A with functional electrical stimulation may not have a difference in efficacy when compared to Botulinum toxin A injection for improving quality of life.	1	Johnson et al. 2004

Other Associated Outcome Measures

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Botulinum Toxin A may produce greater improvements in upper extremity function than Placebo.	1	Prazeres et al. 2018
1b	Botulinum Toxin A with Electrical Stimulation may not have a difference in efficacy when compared to Botox Injections (50U-120U) with neuromuscular electrical stimulation of Injected Agonist Muscles for improving upper extremity function.	1	Lannin et al. 2018

Key Points

- Botulinum Toxin A may be beneficial for improving biomechanical gait measures, spasticity, gait endurance, and quality of life, but not biomechanical balance measures, muscle strength, aerobic measures, pain, activities of daily living, gait speed, and functional mobility, after stroke when compared to Placebo; the literature is mixed regarding motor recovery and range of motion.
- The literature is mixed regarding the effect of Botulinum Toxin A with Ankle-foot Orthosis on motor recovery, spasticity, activities of daily living, and balance after stroke when compared to Conventional rehabilitation.
- Botulinum toxin A (190-320U) with ankle-foot orthosis may be beneficial for improving biomechanical gait measures and spasticity, but not gait speed, after stroke when compared to Botulinum toxin A (190-320U).
- Botulinum toxin A (100U) with Serial casting and stretching and gait training may be beneficial for improving spasticity and range of motion, but not muscle strength, gait speed, gait endurance, and functional mobility, after stroke when compared to Botulinum toxin A (100U) with Taping and stretching and gait training.
- Botulinum Toxin A with Casting or Taping may not be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to Botulinum toxin A (75- 100U) with Sham taping and home exercises.
- Botulinum toxin A (100U) injection into tibialis posterior with ankle-foot adhesive taping may not be beneficial for improving biomechanical gait measures, spasticity, range of motion, and gait speed after stroke when compared to electromyography-guided Botulinum toxin A (190-320U) injection into several calf muscles.
- Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not be beneficial for improving muscle strength, spasticity, range of motion, gait speed, and gait endurance after stroke when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles.
- Botulinum Toxin A with Electrical Stimulation may not be beneficial for improving spasticity, activities of daily living, and gait endurance after stroke when compared to Botox Injections (50U- 120U) with neuromuscular electrical stimulation of Injected Agonist Muscles.
- Botulinum Toxin A with functional electrical stimulation may be beneficial for improving activities of daily living, gait speed, and aerobic measures, but not quality of life, after stroke when compared to Botulinum toxin A injection; the literature is mixed regarding motor recovery and spasticity.
- Botulinum toxin A (500U) with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, spasticity, and range of motion after stroke when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching.

- Therapeutic ultrasound with Home exercises & conventional therapy may not be beneficial for improving spasticity and range of motion after stroke when compared to transcutaneous electrical nerve stimulation with Home exercises & conventional therapy.
- Therapeutic ultrasound with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Botulinum Toxin A with transcutaneous electrical nerve stimulation may not be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to High-dose Botulinum toxin (400U) with Sham electrical stimulation.
- Botulinum toxin (200U) may be beneficial for improving spasticity, but not biomechanical gait measures, range of motion, gait speed, and functional mobility, after stroke when compared to Neurotomy.
- Botulinum Toxin A (400 U) may be beneficial for improving spasticity, but not range of motion, after stroke when compared to Phenol.
- Location of Injection may not be beneficial for improving spasticity, range of motion, gait speed, and functional mobility after stroke when compared to Distal gastrocnemius Botulinum toxin A injection 200U.
- Botulinum toxin A (100U) in mid belly of the gastrocnemius with placebo injected in distal of popliteal fossa may not be beneficial for improving motor recovery, spasticity, range of motion, and gait speed after stroke when compared to Botulinum toxin A (100U) at distal to the popliteal fossa with placebo injected in mid belly.
- Dosage of Injection may not be beneficial for improving motor recovery, biomechanical gait measures, range of motion, pain, and gait endurance after stroke when compared to Placebo; the literature is mixed regarding spasticity.
- Low-dose/low- concentration Botulinum toxin A may not be beneficial for improving gait speed after stroke when compared to Low-dose/high- concentration botulinum toxin A or High-dose/low- concentration botulinum toxin A or High-dose/high- concentration botulinum toxin A; the literature is mixed regarding spasticity and functional mobility.
- Botulinum toxin A with Conventional Therapy (300U) may be beneficial for improving spasticity, but not activities of daily living and gait speed, after stroke when compared to Botulinum toxin A with Conventional Therapy (100U).
- OnabotulinumtoxinA (200U) may not be beneficial for improving spasticity after stroke when compared to OnabotulinumtoxinA (300U); the literature is mixed regarding range of motion, pain, and functional mobility.
- Botulinum toxin A (167U) may not be beneficial for improving pain after stroke when compared to Botulinum toxin A (322U); Botulinum toxin A (167U) may result in lesser improvements in spasticity and gait speed when compared to Botulinum toxin A (322U).
- Botulinum toxin A (167U) may not be beneficial for improving pain after stroke when compared to Botulinum toxin A (540U); Botulinum toxin A (167U) may result in lesser improvements in spasticity when compared to Botulinum toxin A (540U); the literature is mixed regarding gait speed.
- Botulinum toxin A (322U) may not be beneficial for improving spasticity and pain after stroke when compared to Botulinum toxin A (540U); the literature is mixed regarding gait speed.
- Ultrasonography guided Botulinum toxin A (1000U) may not be beneficial for improving motor recovery, spasticity, activities of daily living, and gait speed after stroke when compared to Electrical stimulation guided Botulinum toxin A (1000U).
- Botulinum toxin A (200U) by ultrasonography may not be beneficial for improving spasticity and range of motion after stroke when compared to Botulinum toxin A (200U) by electrical stimulation.
- Botulinum toxin A (200U) by ultrasonography may not be beneficial for improving spasticity after stroke when compared to Botulinum toxin A (200U) by palpation; Botulinum toxin A (200U) by ultrasonography may result in lesser improvements in range of motion when compared to Botulinum toxin A (200U) by palpation.

- Botulinum toxin A (200U) by electrical stimulation may not be beneficial for improving spasticity after stroke when compared to Botulinum toxin A (200U) by palpation; Botulinum toxin A (200U) by electrical stimulation may result in lesser improvements in range of motion when compared to Botulinum toxin A (200U) by palpation.
- Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may be beneficial for improving gait speed, but not spasticity, gait endurance, and functional mobility, after stroke when compared to Botulinum Toxin A Injection.
- Botox Combined with Robotics may be beneficial for improving gait speed, gait endurance, and functional mobility, but not spasticity and range of motion, after stroke when compared to Botox and Conventional Therapy; the literature is mixed regarding balance.
- Botulinum Toxin A with electromyography Biofeedback Treatment and Conventional Care may not be beneficial for improving biomechanical gait measures, spasticity, and gait speed after stroke when compared to Botulinum Toxin A with Conventional Care.
- Forward Treadmill Training with Botulinum Toxin may be beneficial for improving biomechanical balance measures and gait speed, but not biomechanical gait measures and spasticity, after stroke when compared to Backward Treadmill Training with Botulinum Toxin.
- Botulinum Toxin A may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Conventional Therapy.
- Botulinum Toxin A (50-100U) + Isokinetic training may not be beneficial for improving biomechanical gait measures, muscle strength, spasticity, gait speed, and gait endurance after stroke when compared to Botulinum Toxin A (50-100U).
- Received co-injection of abobotulinumtoxinA (aboBoNT-A) in both the upper and lower limbs during treatment cycle 3 and 4 may not be beneficial for improving gait speed after stroke when compared to 1000-1500 U total botulinum toxin lower limb with upper limb injection.
- Botulinum neurotoxin Type A with functional electrical stimulation and conventional physiotherapy may not be beneficial for improving aerobic measures and gait speed after stroke when compared to Conventional physiotherapy.
- Backward treadmill training with botulinum toxin type A therapy may be beneficial for improving biomechanical balance measures and gait speed, but not biomechanical gait measures and spasticity, after stroke when compared to forward treadmill training with botulinum toxin type A therapy.

Summary of Key Points: Botulinum Toxin

Intervention	Control(s)	Function domain(s)	Effect
Botulinum Toxin A	Placebo	Biomechanical gait measures, spasticity, gait endurance, quality of life	+
Botulinum Toxin A	Placebo	Biomechanical balance measures, muscle strength, aerobic measures, pain, activities of daily living, gait speed, functional mobility	–
Botulinum Toxin A	Placebo	Motor recovery, range of motion	=
Botulinum Toxin A with Ankle-foot Orthosis	Conventional rehabilitation	Motor recovery, spasticity, activities of daily living, balance	=
Botulinum toxin A (190-320U) with ankle-foot orthosis	Botulinum toxin A (190-320U)	Biomechanical gait measures, spasticity	+
Botulinum toxin A (190-320U) with ankle-foot orthosis	Botulinum toxin A (190-320U)	Gait speed	–
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with Taping and stretching and gait training	Spasticity, range of motion	+

Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with Taping and stretching and gait training	Muscle strength, gait speed, gait endurance, functional mobility	–
Botulinum Toxin A with Casting or Taping	Botulinum toxin A (75- 100U) with Sham taping and home exercises	Spasticity, range of motion, gait speed	–
Botulinum toxin A (100U) injection into tibialis posterior with ankle-foot adhesive taping	electromyography-guided Botulinum toxin A (190-320U) injection into several calf muscles	Biomechanical gait measures, spasticity, range of motion, gait speed	–
Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles	Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles	Muscle strength, spasticity, range of motion, gait speed, gait endurance	–
Botulinum Toxin A with Electrical Stimulation	Botox Injections (50U- 120U) with neuromuscular electrical stimulation of Injected Agonist Muscles	Spasticity, activities of daily living, gait endurance	–
Botulinum Toxin A with functional electrical stimulation	Botulinum toxin A injection	Activities of daily living, gait speed, aerobic measures	+
Botulinum toxin A (500U) with functional electrical stimulation	Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching	Biomechanical gait measures, spasticity, range of motion	–
Botulinum Toxin A with functional electrical stimulation	Botulinum toxin A injection	Aerobic measures, gait speed	+
Botulinum Toxin A with functional electrical stimulation	Botulinum toxin A injection	Quality of life	–
Therapeutic ultrasound with Home exercises & conventional therapy	transcutaneous electrical nerve stimulation with Home exercises & conventional therapy	Spasticity, range of motion	–
Therapeutic ultrasound with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy	Spasticity, range of motion	–
Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy	Spasticity, range of motion	–
Botulinum Toxin A with transcutaneous electrical nerve stimulation	High-dose Botulinum toxin (400U) with Sham electrical stimulation	Spasticity, range of motion, gait speed	–
Botulinum toxin (200U)	Neurotomy	Spasticity	+
Botulinum toxin (200U)	Neurotomy	Biomechanical gait measures, range of motion, gait speed, functional mobility	–
Botulinum Toxin A (400 U)	Phenol	Spasticity	+
Botulinum Toxin A (400 U)	Phenol	Range of motion	–
Location of Injection	Distal gastrocnemius Botulinum toxin A injection 200U	Spasticity, range of motion, gait speed, functional mobility	–
Botulinum toxin A (100U) in mid belly of the gastrocnemius with placebo injected in distal of popliteal fossa	Botulinum toxin A (100U) at distal to the popliteal fossa with placebo injected in mid belly	Motor recovery, spasticity, range of motion, gait speed	–
Dosage of Injection	Placebo	Spasticity	=
Low-dose/low- concentration Botulinum toxin A	Low-dose/high- concentration botulinum toxin A or High-dose/low- concentration	Gait speed	–

	botulinum toxin A or High-dose/high- concentration botulinum toxin A

Antispastic Drugs

Adopted from: https://www.indiamart.com/proddetail/baclofen-ip-20249295097.html

Antispastic drugs are used for spastic hypertonia of cerebral origin, usually in oral form, and often include baclofen and tizanidine. These non-selective agents mimic the effects of neurotransmitters in the central nervous system. Tolperisone is a centrally acting muscle relaxant that decreases the frequency and amplitude of action potentials in the membrane. Tizanidine and dantrolene are other oral medications used for management of spasticity. When oral medicines are not adequate, injections of intrathecal baclofen may also be used (Rushton et al., 2002).

A total of nine RCTs were found that evaluated antispastic drugs for lower extremity motor rehabilitation. One RCT compared Tolperisone with Placebo (Stamenova et al. 2005). Three RCTs compared Intrathecal Baclofen with Placebo (Creamer et al. 2018; Meythaler et al. 2001a; Meythaler et al. 1999). One RCT compared Dantrolene with Placebo (Ketel & Kolb 1984). One RCT compared Tizanidine with Baclofen (Medici et al. 1989). Two RCTs compared Tizanidine with Placebo (Maupas et al. 2004; Meythaler et al. 2001b). One RCT compared Magnesium Sulphate Iontophoresis with Stretching (Hassan et al. 2022).

The methodological details and results of all nine RCTs are presented in Table 47.

Table 47. RCTs Evaluating Antispastic Drugs for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Tolperisone vs Placebo		
Stamenova et al. (2005) RCT (7) Nstart=120 Nend=97 TPS=Chronic A vs 0	E: Tolperisone hydrochloride (50mg tablets) C: Placebo Duration: 2 tablets/session, 3sessions/d - starting dose (working up to total dosage of 300-900mg/d), for 4wks	E vs C: Ashworth Scale (+exp) 2min Walk Test (+exp) Modified Barthel Index (+exp) Safety Physical Exam and Vital Signs (-) Laboratory Screening (-) ECG Test (-) Adverse Events (-)

Intrathecal Baclofen vs Placebo		
Creamer et al. (2018) RCT (6) Nstart=60 Nend=48 TPS=Chronic A vs 0	E: Intrathecal Baclofen Pump + Conventional Physical Therapy C: Conventional Medical Management (including oral antispastic) + Conventional PT Duration: 21-25d run-in- phase & 6mo active trial phase.	E vs C: Ashworth Scale (+exp) Functional Independence Measure (-) Motor function (-) Cognition (-)
Meythaler et al. (2001a) RCT crossover (6) Nstart=22 Nend=13 TPS=Chronic A vs 0	E: Intrathecal baclofen (50µg) C: Placebo Duration: 50µg intrathecal baclofen daily for 1yr	E vs C: Modified Ashworth Scale (+exp) Penn Spasm Frequency Scale (+exp) Reflex Scale (+exp)
Meythaler et al. (1999) RCT crossover (7) Nstart=6 Nend=6 TPS=Chronic A vs B	E: Continuously intrathecally administered bolus injuection of 50µg Baclofen C: Continuously intrathetcally administered bolus injection of normal saline. Duration: 3mth	E vs C: Modified Ashworth Scale (+exp)
Dantrolene vs Placebo		
Ketel & Kolb (1984) RCT (4) Nstart=18 Nend=14 TPS=Chronic A vs 0	E: Dantrolene C: Placebo Duration: 25mg of Dantrolene, 2-3doses/d, for 6wks	E vs C: Clonus (+exp) Resistance to passive movement scale (+exp) Trunk muscle strength (+exp) Lower extremity muscle strength (+exp) Tendon reflex (+exp)
Tizanidine vs Baclofen		
Medici et al. (1989) RCT (6) Nstart=30 Nend=25 TPS=Chronic A vs B	E1: Tizanidine (8mg, titrated up to max 20mg) E2: Baclofen (20mg, titrated up to max 50mg) Duration: Continued at optimal dose for 30wks maintenance phase	E1 vs E2: Ashworth Scale (-) Muscle Spasms (-) Clonus (-) Muscle Strength (-) Functional Assessment Pedersen Scale (-) Physician's Global Assessment of Clinical Changes (-) Global Assessment of Antispastic Efficacy (-)
Tizanidine vs Placebo		
Maupas et al. (2004) RCT crossover (6) Nstart=14 Nend=14 TPS=Subacute A vs 0	E: Tizanidine (150µg/kg) C: Placebo Duration: Single dose – 10d washout	E vs C: Hmax/Mmax (-) H Reflex (+exp) Modified Ashworth Score (+exp)
Meythaler et al. (2001b) RCT crossover (6) Nstart=17 Nend=15 TPS=Chronic A vs 0	E: Tizanidine (12- 36mg/d) C: Placebo Duration: 12-36mg/d, 7d/wk, for 6wks – 1wk washout	E vs C: Ashworth Scale Lower Extremity (+exp) Upper Extremity (+exp) Penn Spasm Frequency Scale (-) Tendon Reflex Scale (-)

		Range of Motion (-) Functional Independence Measure – Motor Scale (-) Craig Handicap Assessment and Reporting Technique (-) Adverse Events (-)
Magnesium Sulphate Iontophoresis vs Stretching		
Hassan et al. (2022) RCT (7) Nstart=50 Nend=50 TPS=Chronic A vs B	E: MgSO4 iontophoresis C: Stretching excercises Duration: 2d/wk, for 4wks	E vs C: EMG During Rest (+exp) During Activity (+exp) Step Length (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

BIOMECHANICAL GAIT MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Magnesium Sulphate Iontophoresis may produce greater improvements in biomechanical gait measures than Stretching.	1	Hassan et al. 2022

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Dantrolene may produce greater improvements in muscle strength than Placebo.	1	Ketel & Kolb 1984
1b	Tizanidine (8mg, titrated up to max 20mg) may not have a difference in efficacy when compared to Baclofen (20mg, titrated up to max 50mg) for improving muscle strength.	1	Medici et al. 1989

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Tolperisone may produce greater improvements in spasticity than Placebo.	1	Stamenova et al. 2005
1a	Intrathecal Baclofen may produce greater improvements in spasticity than Placebo.	3	Creamer et al. 2018; Meythaler et al. 2001a; Meythaler et al. 1999
2	Dantrolene may produce greater improvements in spasticity than Placebo.	1	Ketel & Kolb 1984

1b	Tizanidine (8mg, titrated up to max 20mg) may not have a difference in efficacy when compared to Baclofen (20mg, titrated up to max 50mg) for improving spasticity.	1	Medici et al. 1989
1a	There is conflicting evidence about the effect of Tizanidine when compared to Placebo for improving spasticity.	2	Maupas et al. 2004; Meythaler et al. 2001b

RANGE OF MOTION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Tizanidine may not have a difference in efficacy when compared to Placebo for improving range of motion.	1	Meythaler et al. 2001b

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Tizanidine when compared to Placebo for improving neurophysiological measures.	1	Maupas et al. 2004
1b	Magnesium Sulphate Iontophoresis may produce greater improvements in neurophysiological measures than Stretching.	1	Hassan et al. 2022

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Tolperisone may not have a difference in efficacy when compared to Placebo for improving activities of daily living.	1	Stamenova et al. 2005
1b	Intrathecal Baclofen may not have a difference in efficacy when compared to Placebo for improving activities of daily living.	1	Creamer et al. 2018
1b	Tizanidine may not have a difference in efficacy when compared to Placebo for improving activities of daily living.	1	Meythaler et al. 2001b

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Tolperisone may produce greater improvements in gait endurance than Placebo.	1	Stamenova et al. 2005

Other Associated Outcome Measures

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Tizanidine may produce greater improvements in upper extremity function than Placebo.	1	Meythaler et al. 2001b

Key Points

- Tolperisone may be beneficial for improving spasticity and gait endurance, but not activities of daily living, after stroke when compared to Placebo.
- Intrathecal Baclofen may be beneficial for improving spasticity, but not motor recovery and activities of daily living, after stroke when compared to Placebo.

- Dantrolene may be beneficial for improving muscle strength and spasticity after stroke when compared to Placebo.
- Tizanidine (8mg, titrated up to max 20mg) may not be beneficial for improving muscle strength and spasticity after stroke when compared to Baclofen (20mg, titrated up to max 50mg).
- Tizanidine may not be beneficial for improving range of motion and activities of daily living after stroke when compared to Placebo; the literature is mixed regarding spasticity and neurophysiological measures.
- Magnesium Sulphate Iontophoresis may be beneficial for improving biomechanical gait measures and neurophysiological measures after stroke when compared to Stretching.

Summary of Key Points: Antispastic Drugs

Intervention	Control(s)	Function domain(s)	Effect
Tolperisone	Placebo	Spasticity, gait endurance	+
Tolperisone	Placebo	Activities of daily living	−
Intrathecal Baclofen	Placebo	Spasticity	+
Intrathecal Baclofen	Placebo	Motor recovery, activities of daily living	−
Dantrolene	Placebo	Muscle strength, spasticity	+
Tizanidine (8mg, titrated up to max 20mg)	Baclofen (20mg, titrated up to max 50mg)	Muscle strength, spasticity	−
Tizanidine	Placebo	Range of motion, activities of daily living	−
Tizanidine	Placebo	Spasticity, neurophysiological measures	=
Magnesium Sulphate Iontophoresis	Stretching	Biomechanical gait measures, neurophysiological measures	+

Cerebrolysin

Adopted from: http://www.gerovitalshop.eu/it/home/18-cerebrolysin-5ml.html

Cerebrolysin is a medication that is a mixture of distinct swine brain-derived peptides that have shown similar pharmacodynamic properties with endogenous neurotrophic factors (Plosker & Gauthier, 2009). It has shown neuroprotective effects both in vitro and in neurodegenerative animal models (Plosker & Gauthier, 2009). In humans, there has been some conflicting evidence, but some studies suggest it could help with cognitive rehabilitation in a number of neurological conditions (Ladurner et al., 2005; Zhang et al., 2015). These peptides could act on the molecular level to also help improve motor outcomes in the lower extremity (Chang et al. 2016).

A total of one RCTs were found that evaluated cerebrolysin for lower extremity motor rehabilitation. One RCT evaluated taping interventions (Chang et al. 2016).

The methodological details and results of all one RCTs are presented in Table 48.

Table 48. RCTs Evaluating Cerebrolysin for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)
Chang et al. (2016) RCT (7) Nstart=70 Nend=66 TPS=Acute A vs 0	E: Cerebrolysin (30ml) + standard rehabilitation C: Placebo (100mL) + standard rehabilitation Duration: 1dose/d, 21d injection & 3hr, 5d/wk, for 3wks standard rehabilitation	E vs C: Fugl-Meyer Assessment (-) Functional neuroimaging (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

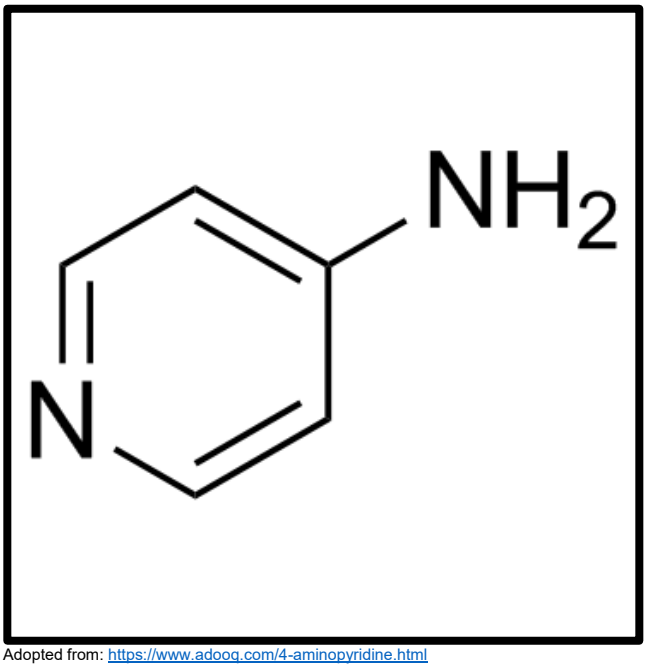
1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Taping may not have a difference in efficacy when compared to no taping, sham taping, or conventional therapy for improving motor recovery.	1	Chang et al. 2016



Key Points

- Taping may not be beneficial for improving motor recovery after stroke when compared to no taping, sham taping, or conventional therapy.

Summary of Key Points: Cerebrolysin

Intervention	Control(s)	Function domain(s)	Effect
Taping	no taping, sham taping, or conventional therapy	Motor recovery	–

4-Aminopyridine

Adopted from: https://www.adooq.com/4-aminopyridine.html

4-aminopyridine (fampridine, dalfampridine) is an organic pyridine that blocks the opening of intercellular potassium channels, ultimately prolonging neuronal repolarization (Simpson et al. 2015). This can increase neuron excitability and conduction strength, particularly in unmyelinated fibers. In mammalian motor neurons, it greatly potentiates the transmitter release at the unmyelinated neuromuscular junction (Sherratt et al., 1980). Although often used for the treatment of multiple sclerosis, its ability to improve neuromuscular signaling could prove effaceable for lower limb rehabilitation in stroke survivors as well.

A total of two RCTs were found that evaluated 4-Aminopyridine for lower extremity motor rehabilitation. Two RCTs compared Dalfampridine with Placebo (Page et al. 2020; Simpson et al. 2015).

The methodological details and results of all two RCTs are presented in Table 49.

Table 49. RCTs Evaluating 4-Aminopyridine for Lower Extremity Motor Rehabilitation

Authors (Year) Study Design (PEDro Score) Sample Size start/end Time post stroke category Study design	Interventions Duration: Session length, frequency per week for total number of weeks	Outcome Measures Result (direction of effect)
Dalfampridine vs Placebo		
Page et al. (2020) RCT (6) Nstart=377 Nend=368 TPS=Chronic A1 vs A2 vs 0	E1: Dalfampridine-extended release (10mg) E2: Dalfampridine-extended release (7.5mg) C: Placebo Duration: 2doses/d for 12wks	E1/E2 vs C: 2min Walk test (-) Walk-12 test (+exp1) Timed Up and Go (-) Adverse events (-)

Biologics and Targeted Molecular Therapies

Adopted from: https://unsplash.com/

Biologics and targeted molecular therapies may be effective for promoting motor recovery post stroke. Biologics are defined as drugs which are derived from living organisms or from their cells (Health Canada, 2019). Common examples of biologics include antibodies and insulin. In this chapter, targeted agents refer to compounds that act on specific biological pathways related to neural repair and recovery. There are many pathways for promoting recovery including mitochondrial, neurotrophic and oxygen regulation (Mocchetti, 2005; Russo et al., 2018). Overall, these agents aim to reduce neuronal damage and promote neuroplasticity.

There are no approved biologics for promoting stroke motor recovery (Lin et al., 2018). Despite this paucity of approved clinically approved agents, there remains investigations into the application of biological and targeted therapies.

A total of seven RCTs were found that evaluated biologics and targeted molecular therapies for lower extremity motor rehabilitation. One RCT compared Granulocyte-colony Stimulating Factor with Placebo (England et al. 2012). One RCT compared Ganglioside GM1 with Placebo (SASS investigators 1994). One RCT compared Cutamesine with Placebo (Urfer et al. 2014). Three RCTs compared Mesenchymal Stem Cell Injection with Placebo or Conventional Therapy (Lee et al. 2022a; Chung et al. 2021; Jaillard et al. 2020). One RCT compared Neuronal Cell with Conventional Therapy (Kondziolka et al. 2005).

The methodological details and results of all seven RCTs are presented in Table 50.

Table 50. RCTs Evaluating Biologics and Targeted Molecular Therapies for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Granulocyte-colony Stimulating Factor vs Placebo

Key Points

- Granulocyte-colony Stimulating Factor may not be beneficial for improving activities of daily living after stroke when compared to Placebo.
- Ganglioside GM1 may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Cutamesine may not be beneficial for improving activities of daily living and gait speed after stroke when compared to Placebo; the literature is mixed regarding motor recovery.
- Mesenchymal Stem Cell Injection may not be beneficial for improving motor recovery, muscle strength, neurophysiological measures, activities of daily living, and functional mobility after stroke when compared to Placebo or Conventional Therapy.
- Neuronal Cell may not be beneficial for improving motor recovery and quality of life after stroke when compared to Conventional Therapy.
- 5million implanted human neuronal cells with Conventional rehabilitation may not be beneficial for improving motor recovery after stroke when compared to 10million implanted human neuronal cells with Conventional rehabilitation.

Summary of Key Points: Biologics and Targeted Molecular Therapies

Intervention	Control(s)	Function domain(s)	Effect
Granulocyte-colony Stimulating Factor	Placebo	Activities of daily living	–

Ganglioside GM1	Placebo	Motor recovery, activities of daily living	–
Cutamesine	Placebo	Activities of daily living, gait speed	–
Cutamesine	Placebo	Motor recovery	=
Mesenchymal Stem Cell Injection	Placebo or Conventional Therapy	Motor recovery, muscle strength, neurophysiological measures, activities of daily living, functional mobility	–
Neuronal Cell	Conventional Therapy	Motor recovery, quality of life	–
5million implanted human neuronal cells with Conventional rehabilitation	10million implanted human neuronal cells with Conventional rehabilitation	Motor recovery	–

Anabolic Steroids

Adopted from: https://unsplash.com/

Anabolic steroids refer to molecular compounds derived from testosterone (Kuhn, 2002). These compounds promote anabolic effects including protein synthesis and muscle growth with negligible androgenizing effects (Mottram & George, 2000). Cerebrovascular accidents lead to reduced muscle function through decreased neural stimulation and activation impairment. To address this, anabolic steroids have been proposed as a possible addition to resistance training to counteract the significant loss in muscle mass and power in stroke survivors which can be as low as 60% of predicted in the lower limb (Patten et al., 2004; Shimodozono et al., 2010).

A total of one RCTs were found that evaluated anabolic steroids for lower extremity motor rehabilitation. One RCT evaluated taping interventions (Okamoto et al. 2011).

The methodological details and results of all one RCTs are presented in Table 51.

Table 51. RCTs Evaluating Anabolic Steroids for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Okamoto et al. (2011) RCT (7) Nstart=26	E: Metenolone enanthate (Anabolic steroid) injection (100mg) + Usual therapy C: Usual therapy	E vs C: Cross Sectional Area (+exp) Affected (+exp)

Nend=26 TPS=Subacute A vs 0	Duration: 1d/wk for 6wks - Steroid injection, 80- 120min/d for 6wks - Usual therapy	Unaffected (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Taping may produce greater improvements in muscle strength than no taping, sham taping, or conventional therapy.	1	Okamoto et al. 2011

Key Points

- Taping may be beneficial for improving muscle strength after stroke when compared to no taping, sham taping, or conventional therapy.

Summary of Key Points: Anabolic Steroids

Intervention	Control(s)	Function domain(s)	Effect
Taping	no taping, sham taping, or conventional therapy	Muscle strength	+

Supplements and Vitamins

Adopted from: https://unsplash.com/

Nutrition, in addition to physical and cognitive focussed rehabilitation is critical in optimizing post- stroke recovery. Stroke survivors are at increased risk of developing dietary-related illnesses including sarcopenia and osteoporosis. Moreover, poor nutrition status may hinder gains in both physical and cognitive rehabilitation. Emerging evidence demonstrates that dietary supplements can be associated with better effectiveness of post-stroke rehabilitation as well as brain recovery (Zielińska-Nowak et al., 2021). Likewise, accumulating evidence points towards the effectiveness of vitamin supplementation on improving post-stroke motor recovery (Utkan Karasu & Kaymak Karataş, 2021). Common vitamins studied in post-stroke rehabilitation include Vitamin B, C and D (Lasoń et al., 2022).

A total of eight RCTs were found that evaluated supplements and vitamins for lower extremity motor rehabilitation. One RCT compared Dietary Protein Supplement with Cycle Ergometer with Carbohydrate Supplement with Cycle Ergometer (Cheng et al. 2020). Three RCTs evaluated Leucine-enriched Amino Acid Supplementation (Nakagawa et al. 2024; Ikeda et al. 2020; Yoshimura et al. 2019). One RCT compared Soymilk Supplementation with Placebo (Liao et al. 2019). Three RCTs evaluated Vitamin and comprehensive Dietary Supplementation (Giovannini et al. 2024; Momosaki et al. 2019; Rabadi et al. 2008).

In addition, four RCTs in which supplements and vitamins formed part of a combined or comparative intervention are cross-referenced at the end of Table 52; their primary listings appear in other tables.

The methodological details and results of all eight RCTs are presented in Table 52.

Table 52. RCTs Evaluating Supplements and Vitamins for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**

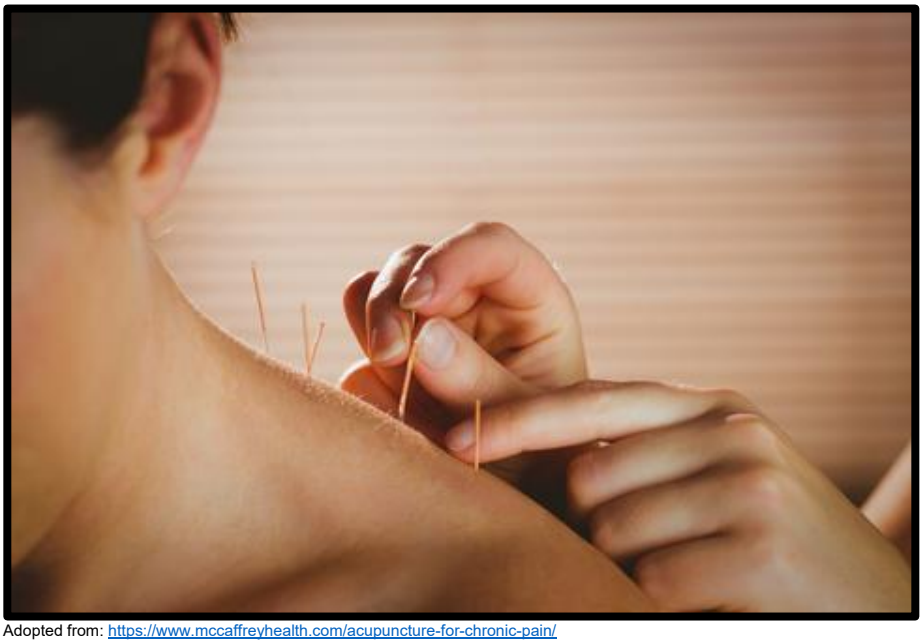
Key Points

- Dietary Protein Supplement with Cycle Ergometer may be beneficial for improving motor recovery, neurophysiological measures, aerobic measures, gait endurance, functional mobility, and balance after stroke when compared to Carbohydrate Supplement with Cycle Ergometer.
- Leucine-enriched Amino Acid Supplementation may be beneficial for improving balance, but not neurophysiological measures, aerobic measures, activities of daily living, gait speed, gait endurance, and

functional mobility, after stroke when compared to Resistance training exercise program; the literature is mixed regarding muscle strength.



- Primary motor area rTMS or Supplementary motor area rTMS may be beneficial for improving motor recovery and balance after stroke when compared to Sham rTMS.
- Soymilk Supplementation may be beneficial for improving gait speed and gait endurance, but not functional mobility, after stroke when compared to Placebo.
- Vitamin and comprehensive Dietary Supplementation may be beneficial for improving functional mobility, balance, and quality of life, but not muscle strength, gait speed, and motor recovery, after stroke when compared to regular meds (meds required for their clinical condition) with intensive rehabilitation treatment; the literature is mixed regarding gait endurance and activities of daily living.
- Primary motor area repetitive transcranial magnetic stimulation may be beneficial for improving motor recovery, neurophysiological measures, and balance after stroke when compared to Sham repetitive transcranial magnetic stimulation.
- Primary motor area repetitive transcranial magnetic stimulation may not be beneficial for improving motor recovery after stroke when compared to Supplementary motor area repetitive transcranial magnetic stimulation; Primary motor area repetitive transcranial magnetic stimulation may result in lesser improvements in neurophysiological measures and balance when compared to Supplementary motor area repetitive transcranial magnetic stimulation.
- Intermittent theta burst stimulation unilateral cerebellar area (CB Single group) may not be beneficial for improving balance after stroke when compared to intermittent theta burst stimulation Cerebellar primary motor cortex area (CB-M1 group) or intermittent theta burst stimulation Cerebellar Supplementary Motor Area (CB-SMA group).
- DLBS1033 supplement (Lumbrokinase) with therapy may be beneficial for improving motor recovery and activities of daily living after stroke when compared to therapy.
- Leucine enriched amino acid with resistant training may be beneficial for improving muscle strength, but not neurophysiological measures, after stroke when compared to Resistant training; the literature is mixed regarding activities of daily living.

Summary of Key Points: Supplements and Vitamins

Intervention	Control(s)	Function domain(s)	Effect
Dietary Protein Supplement with Cycle Ergometer	Carbohydrate Supplement with Cycle Ergometer	Motor recovery, neurophysiological measures, aerobic measures, gait endurance, functional mobility, balance	+
Leucine-enriched Amino Acid Supplementation	Resistance training exercise program	Neurophysiological measures, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility	−
Leucine-enriched Amino Acid Supplementation	Resistance training exercise program	Balance	+
Leucine-enriched Amino Acid Supplementation	Resistance training exercise program	Activities of daily living, functional mobility	−
Soymilk Supplementation	Placebo	Gait speed, gait endurance	+
Soymilk Supplementation	Placebo	Functional mobility	−
Vitamin and comprehensive Dietary Supplementation	regular meds (meds required for their clinical condition) with intensive rehabilitation treatment	Functional mobility, balance, quality of life	+
Vitamin and comprehensive Dietary Supplementation	regular meds (meds required for their clinical condition) with intensive rehabilitation treatment	Muscle strength, gait speed, motor recovery	−

Vitamin and comprehensive Dietary Supplementation	regular meds (meds required for their clinical condition) with intensive rehabilitation treatment	Motor recovery	−
Primary motor area repetitive transcranial magnetic stimulation	Sham repetitive transcranial magnetic stimulation	Motor recovery, neurophysiological measures, balance	+
Primary motor area repetitive transcranial magnetic stimulation	Supplementary motor area repetitive transcranial magnetic stimulation	Motor recovery	−
Primary motor area repetitive transcranial magnetic stimulation	Supplementary motor area repetitive transcranial magnetic stimulation	Neurophysiological measures, balance	−
Intermittent theta burst stimulation unilateral cerebellar area (CB Single group)	intermittent theta burst stimulation Cerebellar primary motor cortex area (CB-M1 group) or intermittent theta burst stimulation Cerebellar Supplementary Motor Area (CB-SMA group)	Balance	−
DLBS1033 supplement (Lumbrokinase) with therapy	therapy	Motor recovery, activities of daily living	+
Primary motor area rTMS or Supplementary motor area rTMS	Sham rTMS	Motor recovery, balance	+
Leucine enriched amino acid with resistant training	Resistant training	Muscle strength	+
Leucine enriched amino acid with resistant training	Resistant training	Neurophysiological measures	−
Leucine enriched amino acid with resistant training	Resistant training	Activities of daily living	=
Leucine-enriched Amino Acid Supplementation	Resistance training exercise program	Muscle strength	=
Vitamin and comprehensive Dietary Supplementation	regular meds (meds required for their clinical condition) with intensive rehabilitation treatment	Gait endurance, activities of daily living	=

Acupuncture and Massage

Adopted from: https://www.mccaffreyhealth.com/acupuncture-for-chronic-pain/

The use of acupuncture has recently gained attention as an adjunct to stroke rehabilitation in Western countries even though acupuncture has been a primary treatment method in China for about 2000 years (Baldry, 2005). In China, acupuncture is an acceptable, time-efficient, simple, safe and economical form of treatment used to ameliorate motor, sensation, verbal communication and further neurological functions in post-stroke patients (Wu et al., 2002). According to Rabinstein and Shulman (2003), “Acupuncture is a therapy that involves stimulation of defined anatomic locations on the skin by a variety of techniques, the most common being stimulation with metallic needles that are manipulated either manually or that serve as electrodes conducting electrical currents”. There is a range of possible acupuncture mechanisms that may contribute to the health benefits experienced by stroke patients (Park et al., 2006). For example, acupuncture may stimulate the release of neurotransmitters (Han & Terenius, 1982) and have an effect on the deep structure of the brain (Wu et al., 2002). Lo et al. (2005) established acupuncture, when applied for at least 10 minutes, led to long-lasting changes in cortical excitability and plasticity even after the needle stimulus was removed. With respect to stroke rehabilitation, the benefit of acupuncture has been evaluated most frequently for pain relief and recovery from hemiparesis.

Also, meridian acupressure is a Chinese medicine treatment that involves placing needles on twelve strategic points of the body. These points are known as meridians and placing needles here helps to alleviate the blockage of energy (otherwise known as qi).

A total of 51 RCTs were found that evaluated acupuncture and massage for lower extremity motor rehabilitation. Fifteen RCTs compared Acupuncture Therapy with Conventional Therapy (Hong et al. 2024; Wang et al. 2020a; Wang et al. 2019a; Sanchez-Mila et al. 2018; Na et al. 2018; Chen et al. 2016; Liu et al. 2016a; Bai et al. 2013; Gao et al. 2012; Zhuang et al. 2012; Mao et al. 2008; Park et al. 2005; Alexander et al. 2004; Sze et al. 2002; Johansson et al. 1993). Five RCTs compared Acupuncture with Sham (Chen et al. 2024b; Wang et al. 2023; Ghannadi et al. 2020; Li et al. 2014; Fink et al. 2004). One RCT compared Acupuncture Treatment with No Treatment (Salom-Moreno et al. 2014). One RCT compared Channel Palpation Guided Acupuncture with Traditional Acupuncture (Luo et al. 2018). One RCT compared Scalp Acupuncture and Robot Assisted Training with Basic Treatment (Zhang et al. 2021c). Seven RCTs compared Scalp Acupuncture with Conventional Therapy or Other Modalities (Xie et al. 2022; Wang et al. 2020a; Xiong et al. 2020; Liu et al. 2018; Wang et al. 2018; Zhu et al. 2013; Hegyi et al. 2012). One RCT compared Auricular Intradermal Acupuncture with Conventional Therapy (Miao et al. 2020). Two RCTs compared Acupuncture with Manipulation with Acupuncture (Liu et al. 2009; Zhao et al. 2009). One RCT compared Eye Acupuncture with Body Acupuncture (Lou et al. 2020). Six RCTs evaluated Multifaceted Alternative Medicine Approaches (Sun et al. 2024b; Cui et al. 2023; Shen et al. 2020; Shao et al. 2019; Zhang et al. 2017; Wei et al. 2016). Eight RCTs evaluated Massage and other integrated rehabilitation techniques (Ye et al. 2022; Zhang et al. 2022; Zheng et al. 2021; Chen et al. 2019a; Holt et al. 2019; Yang et al. 2017; Thanakiatpinyo et al. 2014; Zhang et al. 2013). Two RCTs compared Dry Needling with Conventional Rehabilitation

with Conventional Rehabilitation Alone (Kucuktepe et al. 2023; Sanchez Mila et al. 2022). One RCT compared Acupuncture with Robot-Assisted Gait Training with Acupuncture Alone (Hu et al. 2024).

In addition, fourteen RCTs in which acupuncture and massage formed part of a combined or comparative intervention are cross-referenced at the end of Table 53; their primary listings appear in other tables.

The methodological details and results of all 51 RCTs are presented in Table 53.

Table 53. RCTs Evaluating Acupuncture and Massage for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Acupuncture vs Conventional Therapy		
Hong et al. (2024) RCT (5) Nstart=60 Nend=60 TPS=Acute A + B vs B Also in Table 21 (Strength and Resistance Training)	E: Acupuncture + trunk strengthening training + conventional rehab C: Conventional rehab + trunk strengthening training Duration: E: 75min/d (30 min acupuncture + 45 min rehab), 6d/wk, 8 wks; C: 45min/d, 6d/wk for 8wks	E vs C: holden walking scale (+exp) Berg Balance Scale (+exp) 10mWT step length (+exp) step width (+exp) gait speed (+exp)
Wang et al. (2020d) RCT (8) Nstart=134 Nend=124 TPS=Subacute A vs 0	E: Acupuncture + Conventional therapy C: Conventional therapy Duration: 45min/d, 6d/wk, for 4wks Conventional treatment & 6d/wk, for 4wks Acupuncture	E v C: Barthel Index (-) Fugl-Meyer (+exp) Upper limb (-) Lower limb (+exp) Gait analysis (not whole population) Velocity (+exp) Step length (+exp) Cadence (+exp) Step width (+exp) Range of motion Hip (+exp) Knee (+exp) Ankle (-) Peak circumduction (+exp) Peak hip hiking (+exp)
Wang et al. (2019a) RCT (8) Nstart=59 Nend=59 TPS=Subacute A vs 0	E: Acupuncture + conventional therapy C: Conventional therapy Duration: 45min/d, 6d/wk, for 4wks conventional therapy ~20min/d, 6d/wk, for 4wks acupuncture	E vs C: Modified Ashworth Scale (+exp) short intracortical inhibition (+exp) Hmax/Mmax ratio (+exp) Fugl-Meyer Assessment (+exp) Barthel Index (-) motor evoked potential (+exp) surface integrated electromyogram (+exp)
Sanchez-Mila et al. (2018) RCT (7) Nstart=26 Nend=26 TPS=Not reported A + B vs A	E: Bobath + dry needling C: Bobath Duration: 60min/1session	E vs C: Modified modified ashworth scale (+exp) Fugl-meyer scale Motor (-) Balance (+exp) Sensory (+exp)

Also in Table 1 (Neurodevelopmental Techniques and Motor Relearning)		Range of motion (+exp) Joint pain (-) Computerised dynamic posturography using SMART Equitest System MVL non-affected forward (+exp) EPE non-affected (+exp) MXE backward (+exp) MXE affected/non-affected (+exp) DCL backward (+exp) DCL affected backward (+exp)
Na et al. (2018) RCT (6) Nstart=76 Nend=76 TPS=Acute A + B vs 0 Also in Table 55 (Traditional Herbal Medicines)	E: Chinese Traditional therapy (Bath in Chinese herbal medicine + Acupuncture with massage) + Conventional care C: Conventional care Duration: 1session/d, 7d/wk for 4wks - Chinese Traditional therapy (30min/d Traditional bath therapy + 30min/d Acupuncture and Massage); 40min/d for 4wks conventional care	E vs C: Fugl-Meyer assessment (+exp) Modified Barthel index (+exp) Neurological impairments (+exp) Efficacy of treatment (+exp)
Chen et al. (2016) RCT (8) Nstart=250 Nend=241 TPS=Acute A vs 0	E: Acupuncture + conventional therapy C: Conventional therapy Duration: 120min/d, 6d/wk, for 3wks conventional rehabilitation & 30min/d, 6d/wk, for 3wks acupuncture	E vs C: National Institute of Health Stroke Scale (-) Fugl-Meyer Assessment (-) Mini mental state examination (-) Montreal Cognitive Assessment (-)
Liu et al. (2016a) RCT (6) Nstart=38 Nend=31 TPS=Acute A vs 0	E: Acupuncture + conventional therapy C: Conventional therapy Duration: 1session/d, for 2wks (10-14 acupuncture sessions total)	E vs C: National Institutes of Health Stroke Scale (-) Fugl–Meyer assessment (-) functional independence measure (-) modified Rankin Scale (No stats) Barthel Index (No stats)
Bai et al. (2013) RCT (7) Nstart=120 Nend=120 TPS=Subacute A1 vs 0 vs A2	E1: Acupuncture E2: Physiotherapy E3: Acupuncture + PhysiotherapyNI Duration: 30min/d, 6d/wk acupuncture & 45min/d, 6d/wk, for 4wks physiotherapy	E1 vs E2 vs E3: Fugl-Meyer Assessment: (-) Modified Barthel Index (-)
Gao et al. (2012) RCT (5) Nstart=106 Nend=106 TPS=Acute A vs B vs C	E1: Contra-lateral Needling (acupuncture on unaffected limbs) E2: Traditional acupuncture C: Convenional Care Duration: 45min/d, 30d	E1 vs E2: Neurological Deficits Score (+exp1) Modified Barthel Index (+exp1) Fugl-Meyer Assessment (+exp1) E1/E2 vs C: Neurological Deficits Score (+exp1, +exp2) Modified Barthel Index (+exp1, +exp2) Fugl-Meyer Assessment (+exp1, +exp2)
Zhuang et al. (2012) RCT (7) Nstart=295 Nend=274 TPS=Subacute A1 vs A2 vs B	E1: Acupuncture E2: Acupuncture + Physiotherapy C: Physiotherapy based on Bobath approach Duration: 30min/d, 6d/wk, for 4wks acupuncture, 105min/d, 6d/wk, for 4wks PT/OT	E1 V E2 V C: ; Fugl-Meyer Assessment (-) Barthel index (-) Neurologic defect scale (-)

Mao et al. (2008) RCT (5) Nstart=60 Nend=60 TPS=Acute A + B vs 0	E: Acupuncture combined with modern therapy C: Conventional therapy Duration: 30min/d , 5d/wk, acupuncture, 1h/d, 5d/wk, Conventional therapy	E vs C: Fugl-Meyer assessment (No stats) Modified Barthel index (No stats)
Park et al. (2005) RCT (8) Nstart=116 Nend=98 TPS=Acute A vs 0	E: Acupuncture + Conventional rehabilitation C: Sham acupuncture + Conventional rehabilitation Duration: 20min/d, 9-12d/2wks Acupuncture/Sham	E vs C: Motricity Index (-) Barthel Index (-) National Institute of Health Stroke Scale (-) EQ-5D (-) EQ-VAS (-) Nottingham Extended ADL Score (-) Ashworth Spasticity Scale (-) 10-Metre Walk Test (-) 9-Hole Peg Test (-) Bedside Swallow Screening Test (+con)
Alexander et al. (2004) RCT (6) Nstart=32 Nend=29 TPS=Subacute A vs 0	E: Acupuncture + conventional therapy C: Conventional therapy Duration: 30min/d, 7d/wk for 2wk	E vs C: Fugl-Meyer Assessment (-) Lower Extremity (+exp) Functional Independence Measure (-) Tub/Shower Transfer Mobility (+exp)
Sze et al. (2002) RCT (8) Nstart=106 Nend=92 TPS=Acute A vs 0	E: Acupuncture + Standard treatment C: Standard treatment Duration: 95min/d, 2-3-5d/wk, 10wks standard treatment & 30min/d, 2-3-5d/wk, 10wks Acupuncture	E vs C: Fugl-Meyer Assessment (-) Barthel Index (-) Functional Independence Measure (-)
Johansson et al. (1993) RCT (5) Nstart=78 Nend=70 TPS=Acute A vs 0	E: Acupuncture + conventional rehabilitation C: Conventional rehabilitation Duration: 30min/d, 2d/wk, for 10wks	E vs C: Balance (no stat) Motor function (+exp) Mobility (+exp) Barthel Index (+exp) Nottingham Health Profile Energy (+exp) Mobility (+exp) Emotion (+exp) Social Isolation (+exp) Pain (-) Sleep (-)
Acupuncture vs Sham		
Chen et al. (2024b) RCT (8) Nstart=54 Nend=46 TPS=Acute A1 vs A2	E: Acupuncture (Hand-Foot standard acupoints) C: Non-Acupoint Acupuncture Duration: 32min (1min x 12 needles + 20min retention)/d, 10d	E vs C: FMA (+exp) UE (+exp) LE (+exp) Voxel-mirrored homotopic connectivity cerebellum 8 (+exp)
Wang et al. (2023) RCT (6) Nstart=53	E: Shou zu shi er zhen acupuncture C: Sham acupuncture + conventional Duration: 30m/d, 5d/wk, 2wks	E vs C: NIHSS(-) FMA(-)

Nend=40 TPS=Acute A vs 0		fMRI temporal properties(-)
Ghannadi et al. (2020) RCT (9) Nstart=24 Nend=24 TPS=Chronic A vs 0	E: Dry needling in gastrocnemius C: Sham needling Duration: 3 sessions/wk, for 1wk (48 hrs between sessions)	E vs C: Modified Ashworth Scale (+exp) Timed Up-and-Go (+exp) Single Leg Stance (+exp) 10-Metre Walk Test (+exp) Barthel Index (+exp) Active Range of Motion (-) Passive Range of Motion (+exp) Muscle Architecture (+exp)
Li et al. (2014) RCT (8) Nstart=263 Nend=238 TPS=Acute A vs 0	E: Acupuncture ("Wang's Jiaji" acupoints) C: Sham acupuncture Duration: 30min/d, 5d/wk, for 4wks	E vs C: Modified Ashworth scale (+exp) Fugl-Meyer assessment (+exp) Modified Barthel index (+exp) National Institute of Health Stroke Scale (-) Stroke specialized Quality of Life (+exp) Modified Rankin scale (+exp)
Fink et al. (2004) RCT (6) Nstart=25 Nend=25 TPS=Chronic A vs 0	E: Verum acupuncture C: Placebo acupuncture Duration: 30min/d, 2d/wk for 4wks	E vs C: Modified Ashworth Scale (-) Hmax/Mmax Ratio (+exp) Clinical Global Impressions (+con) 2-Minute Walk Test (-) Rivermead Motor Assessment (-) Step Length (-) Cadence (-) Goniometry (-) Pain VAS (-) Nottingham Health Profile (-) Everyday Life Questionnaire (-) Von Zerssen Depression Scale (-)
Acupuncture vs No Treatment		
Salom-Moreno et al. (2014) RCT (7) Nstart=34 Nend=34 TPS=Chronic A vs 0	E: Deep dry needling C: No treatment Duration: Single session	E vs C: Modified Ashworth scale (+exp) Pressure Pain Sensitivity (+exp) Baropodometric Scores of Forefoot Support surface (unaffected/affected) (+exp) Force distribution (unaffected/affected) (-) Percentage of load (unaffected) (+exp) Percentage of load (affected) (-) Baropodometric Scores of Rearfoot Support surface (affected) (+exp) Support surface (unaffected) (-) Force distribution (unaffected/affected) (-) Percentage of load (unaffected/affected) (-) Mean Pressure (unaffected/affected) (+exp) Maximum Pressure (unaffected/affected) (-)

Channel Palpation Guided Acupuncture vs Traditional Acupuncture		
Luo et al. (2018) RCT (8) Nstart=143 Nend=136 TPS=Subacute A vs B	E: Channel palpation guided Acupuncture C: Traditional acupuncture Duration: 30min/d, 5d/wk, for 6wks	E vs C: Fugl-Meyer assessment Motor function (-) Balance (-) Stroke Specific Quality of Life (-) NIH Stroke Scale (-)
Scalp Acupuncture and Robot Assisted Training vs Basic Treatment		
Zhang et al. (2021c) RCT (6) Nstart=231 Nend=212 TPS=Subacute A + B vs A + C + D vs A Also in Table 27 (Electromechanical and Robotic Devices)	E1: Interactive Dynamic Scalp Acupuncture + lower-limb robot training (SA & LLRT simultaneously) + Basic Treatment E2: Scalp Acupuncture + lower- limb robot training (LLRT + SA separately) + Basic Treatment C: Scalp Acupuncture + Basic Treatment Duration: 30min/d, 6d/wk, for 8wks Interactive Dynamic Acupuncture & 30min/d, 6d/wk, for 8wks traditional acupuncture & 30min, 2sessions/d, 6d/wk, for 8wks combination therapy	E1/E2 v C: Fugl-Meyer Lower Extremity (+exp1) Berg balance scale (+exp1) 6-minute walk test (+exp1) Modified Barthel index (+exp1) Stride frequency (+exp1, +exp2) Step length (-) Step width (-) Affected side foot angle (-) Passive range of motion affected side Hip(+exp1) Knee (+exp1) Ankle (+exp1) E1 v E2: Fugl-Meyer Lower Extremity (+exp1) Berg balance scale (+exp1) 6-minute walk test (+exp1) Modified barthel index (+exp1) Stride frequency (+exp1) Step length (-) Step width (-) Affected side foot angle (+exp2) Passive range of motion affected side Hip(+exp1) Knee (+exp1) Ankle (+exp1)
Scalp Acupuncture vs Conventional Therapy or Other Modalities		
Xie et al. Transcutaneous Electrical Acupoint Stimulation)		Motor leg (+exp) Capacity walking (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

2	Contra-lateral Needling (acupuncture on unaffected limbs) may produce greater improvements in activities of daily living than Traditional acupuncture.	1	Gao et al. 2012

2	Traditional acupuncture may produce greater improvements in activities of daily living than Convenional Care.	1	Gao et al. 2012
1a	Acupuncture may produce greater improvements in activities of daily living than Sham.	2	Ghannadi et al. 2020; Li et al. 2014
1b	Scalp Acupuncture and Robot Assisted Training may produce greater improvements in activities of daily living than Basic Treatment.	1	Zhang et al. 2021c
1a	Scalp Acupuncture may produce greater improvements in activities of daily living than Conventional Therapy or Other Modalities.	7	Xie et al. 2022; Wang et al. 2020a; Xiong et al. 2020; Liu et al. 2018; Wang et al. 2018; Zhu et al. 2013; Hegyi et al. 2012
1b	Acupuncture with Manipulation may produce greater improvements in activities of daily living than Acupuncture.	1	Zhao et al. 2009
1b	There is conflicting evidence about the effect of Multifaceted Alternative Medicine Approaches when compared to Meridian Dredging Exercise for improving activities of daily living.	3	Cui et al. 2023; Zhang et al. 2017; Wei et al. 2016
1b	Neuronavigation-assisted aspiration with electroacupuncture may produce greater improvements in activities of daily living than Neuronavigation-assisted aspiration.	1	Zhang et al. 2017
1b	Neuronavigation-assisted aspiration with electroacupuncture may produce greater improvements in activities of daily living than Electroacupuncture.	1	Zhang et al. 2017
1b	There is conflicting evidence about the effect of Neuronavigation-assisted aspiration when compared to Electroacupuncture for improving activities of daily living.	1	Zhang et al. 2017
1b	Electroacupuncture may not have a difference in efficacy when compared to Conservative therapy for improving activities of daily living.	1	Zhang et al. 2017
1a	There is conflicting evidence about the effect of Massage and other integrated rehabilitation techniques when compared to Health education program for improving activities of daily living.	5	Zhang et al. 2022; Zheng et al. 2021; Yang et al. 2017; Thanakiatpinyo et al. 2014; Zhang et al. 2013
2	Virtual reality-assisted gait adaptation training with acupuncture and conventional physical therapy may not have a difference in efficacy when compared to Overground gait adaptation training with acupuncture and conventional physical therapy for improving activities of daily living.	1	Wang et al. 2024e
1b	Joint mobilization with acupuncture may produce greater improvements in activities of daily living than Joint mobilization.	1	Lee et al. 2023b
1b	Joint mobilization with acupuncture may produce greater improvements in activities of daily living than Conventional rehab.	1	Lee et al. 2023b
1b	One session daily high intensity Videogame exercises with medical massage may not have a difference in efficacy when compared to two sessions daily high intensity Videogame exercises with medical massage for improving activities of daily living.	1	Tollar et al. 2021
1b	One session daily high intensity Videogame exercises with medical massage may produce greater improvements in activities of daily living than Standard physical therapy with medical massage.	1	Tollar et al. 2021
1b	Two sessions daily high intensity Videogame exercises with medical massage may not have a difference in efficacy when compared to Standard physical therapy with medical massage for improving activities of daily living.	1	Tollar et al. 2021
1b	Electroacupuncture, usual care may not have a difference in efficacy when compared to Usual care for improving activities of daily living.	1	Cai et al. 2021

1b	Electroacupuncture may not have a difference in efficacy when compared to Sham transcutaneous electrical nerve stimulation for improving activities of daily living.	1	Hopwood et al. 2008
1b	Electroacupuncture with Conventional therapy may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	1	Hsieh et al. 2007
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high- frequency electrostimulation (80Hz) for improving activities of daily living.	1	Johansson et al. 2001
2	There is conflicting evidence about the effect of Electrical Acupuncture with Conventional Therapy when compared to Conventional therapy for improving activities of daily living.	1	Wong et al. 1999

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Acupuncture Therapy may produce greater improvements in gait speed than Conventional Therapy.	3	Hong et al. 2024; Wang et al. 2020d; Park et al. 2005
1b	Acupuncture may produce greater improvements in gait speed than Sham.	1	Ghannadi et al. 2020
2	Multifaceted Alternative Medicine Approaches may produce greater improvements in gait speed than Meridian Dredging Exercise.	1	Shen et al. 2020
1b	Massage and other integrated rehabilitation techniques may produce greater improvements in gait speed than Health education program.	1	Ye et al. 2022
1b	Dry Needling with Conventional Rehabilitation may produce greater improvements in gait speed than Conventional Rehabilitation Alone.	1	Kucuktepe et al. 2023
2	Acupuncture with Robot-Assisted Gait Training may produce greater improvements in gait speed than Acupuncture Alone.	1	Hu et al. 2024
2	Virtual reality-assisted gait adaptation training with acupuncture and conventional physical therapy may produce greater improvements in gait speed than Overground gait adaptation training with acupuncture and conventional physical therapy.	1	Wang et al. 2024e
1b	Joint mobilization with acupuncture may not have a difference in efficacy when compared to Conventional rehab for improving gait speed.	1	Lee et al. 2023b
1b	Joint mobilization with acupuncture may not have a difference in efficacy when compared to Joint mobilization for improving gait speed.	1	Lee et al. 2023b
1b	Interferential current therapy (ICT) stimulation of gastrocnemius with air-pump massage and rehabilitation may produce greater improvements in gait speed than Placebo-ICT with air-pump massage and rehabilitation.	1	Suh et al. 2014a
1b	Electroacupuncture with Conventional therapy may not have a difference in efficacy when compared to Conventional Therapy for improving gait speed.	1	Hsieh et al. 2007
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high- frequency electrostimulation (80Hz) for improving gait speed.	1	Johansson et al. 2001

GAIT ENDURANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Acupuncture may not have a difference in efficacy when compared to Sham for improving gait endurance.	1	Fink et al. 2004
1b	Scalp Acupuncture and Robot Assisted Training may produce greater improvements in gait endurance than Basic Treatment.	1	Zhang et al. 2021c

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Acupuncture Therapy may produce greater improvements in functional mobility than Conventional Therapy.	2	Hong et al. 2024; Alexander et al. 2004
1b	Acupuncture may produce greater improvements in functional mobility than Sham.	1	Ghannadi et al. 2020
2	Massage and other integrated rehabilitation techniques may produce greater improvements in functional mobility than Health education program.	1	Zhang et al. 2022
2	Acupuncture with Robot-Assisted Gait Training may produce greater improvements in functional mobility than Acupuncture Alone.	1	Hu et al. 2024
2	Virtual reality-assisted gait adaptation training with acupuncture and conventional physical therapy may produce greater improvements in functional mobility than Overground gait adaptation training with acupuncture and conventional physical therapy.	1	Wang et al. 2024e
1b	Electroacupuncture with Conventional therapy may produce greater improvements in functional mobility than Conventional Therapy.	1	Kim et al. 2022c
2	Unani Medicine (Herbal and Massage) may produce greater improvements in functional mobility than Western Medicine (Piracetam 800mg).	1	Ahmed et al. 2015
1b	Interferential current therapy (ICT) stimulation of gastrocnemius with air-pump massage and rehabilitation may produce greater improvements in functional mobility than Placebo-ICT with air-pump massage and rehabilitation.	1	Suh et al. 2014a
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high- frequency electrostimulation (80Hz) for improving functional mobility.	1	Johansson et al. 2001

BALANCE			
LoE	**Conclusion Statement**	**RCTs**	**References**
2	Acupuncture Therapy may produce greater improvements in balance than Conventional Therapy.	2	Hong et al. 2024; Johansson et al. 1993
1b	Acupuncture may produce greater improvements in balance than Sham.	1	Ghannadi et al. 2020
1b	Scalp Acupuncture and Robot Assisted Training may produce greater improvements in balance than Basic Treatment.	1	Zhang et al. 2021c
2	There is conflicting evidence about the effect of Multifaceted Alternative Medicine Approaches when compared to Meridian Dredging Exercise for improving balance.	2	Cui et al. 2023; Shao et al. 2019
1a	Massage and other integrated rehabilitation techniques may produce greater improvements in balance than Health education program.	3	Ye et al. 2022; Zhang et al. 2022; Zheng et al. 2021
1b	Dry Needling with Conventional Rehabilitation may produce greater improvements in balance than Conventional Rehabilitation Alone.	1	Kucuktepe et al. 2023

1b	Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) may not have a difference in efficacy when compared to Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) for improving balance.	1	Xu et al. 2024
1b	Interferential current therapy (ICT) stimulation of gastrocnemius with air-pump massage and rehabilitation may produce greater improvements in balance than Placebo-ICT with air-pump massage and rehabilitation.	1	Suh et al. 2014a

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	There is conflicting evidence about the effect of Acupuncture Therapy when compared to Conventional Therapy for improving quality of life.	2	Park et al. 2005; Johansson et al. 1993
1a	Acupuncture may not have a difference in efficacy when compared to Sham for improving quality of life.	2	Li et al. 2014; Fink et al. 2004
1b	Channel Palpation Guided Acupuncture may not have a difference in efficacy when compared to Traditional Acupuncture for improving quality of life.	1	Luo et al. 2018
2	Scalp Acupuncture may produce greater improvements in quality of life than Conventional Therapy or Other Modalities.	1	Hegyi et al. 2012
1b	Multifaceted Alternative Medicine Approaches may not have a difference in efficacy when compared to Meridian Dredging Exercise for improving quality of life.	1	Sun et al. 2024b
1b	There is conflicting evidence about the effect of Massage and other integrated rehabilitation techniques when compared to Health education program for improving quality of life.	2	Chen et al. 2019a; Thanakiatpinyo et al. 2014
1b	Electroacupuncture may not have a difference in efficacy when compared to Sham transcutaneous electrical nerve stimulation for improving quality of life.	1	Hopwood et al. 2008
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high- frequency electrostimulation (80Hz) for improving quality of life.	1	Johansson et al. 2001

Other Associated Outcome Measures

MOOD			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Acupuncture may not have a difference in efficacy when compared to Sham for improving mood.	1	Fink et al. 2004
1b	Massage and other integrated rehabilitation techniques may not have a difference in efficacy when compared to Health education program for improving mood.	2	Chen et al. 2019a; Thanakiatpinyo et al. 2014
1b	Joint mobilization with acupuncture may produce greater improvements in mood than Joint mobilization.	1	Lee et al. 2023b

1b	Joint mobilization with acupuncture may produce greater improvements in mood than Conventional rehab.	1	Lee et al. 2023b
1b	One session daily high intensity Videogame exercises with medical massage may not have a difference in efficacy when compared to physical therapy with medical massage or 60min/d care and 20min/d massage for improving mood.	1	Tollar et al. 2021
1b	One session daily high intensity Videogame exercises with medical massage may not have a difference in efficacy when compared to two sessions daily high intensity Videogame exercises with medical massage for improving mood.	1	Tollar et al. 2021

FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Electroacupuncture may not have a difference in efficacy when compared to Sham transcutaneous electrical nerve stimulation for improving fatigue and sleep.	1	Hopwood et al. 2008

COGNITION			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Acupuncture Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving cognition.	1	Chen et al. 2016
1b	There is conflicting evidence about the effect of Scalp Acupuncture when compared to Conventional Therapy or Other Modalities for improving cognition.	1	Xiong et al. 2020
1b	One session daily high intensity Videogame exercises with medical massage may not have a difference in efficacy when compared to physical therapy with medical massage or 60min/d care and 20min/d massage for improving cognition.	1	Tollar et al. 2021
1b	One session daily high intensity Videogame exercises with medical massage may not have a difference in efficacy when compared to two sessions daily high intensity Videogame exercises with medical massage for improving cognition.	1	Tollar et al. 2021

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Acupuncture Therapy when compared to Conventional Therapy for improving upper extremity function.	2	Wang et al. 2020d; Park et al. 2005
1a	Scalp Acupuncture may not have a difference in efficacy when compared to Conventional Therapy or Other Modalities for improving upper extremity function.	3	Xie et al. 2022; Liu et al. 2018; Zhu et al. 2013
1b	Auricular Intradermal Acupuncture may produce greater improvements in upper extremity function than Conventional Therapy.	1	Miao et al. 2020
1b	Acupuncture with Manipulation may produce greater improvements in upper extremity function than Acupuncture.	1	Zhao et al. 2009
1b	There is conflicting evidence about the effect of Multifaceted Alternative Medicine Approaches when compared to Meridian Dredging Exercise for improving upper extremity function.	2	Sun et al. 2024b; Wei et al. 2016
1a	There is conflicting evidence about the effect of Massage and other integrated rehabilitation techniques when compared to Health education program for improving upper extremity function.	3	Ye et al. 2022; Yang et al. 2017; Zhang et al. 2013

1b	Dry Needling with Conventional Rehabilitation may produce greater improvements in upper extremity function than Conventional Rehabilitation Alone.	1	Kucuktepe et al. 2023
1b	Joint mobilization with acupuncture may not have a difference in efficacy when compared to Conventional rehab for improving upper extremity function.	1	Lee et al. 2023b
1b	Joint mobilization with acupuncture may not have a difference in efficacy when compared to Joint mobilization for improving upper extremity function.	1	Lee et al. 2023b
1b	Electroacupuncture with Conventional therapy may produce greater improvements in upper extremity function than Conventional Therapy.	1	Hsieh et al. 2007
2	Electrical Acupuncture with Conventional Therapy may produce greater improvements in upper extremity function than Conventional therapy.	1	Wong et al. 1999
2	Electroacupuncture with Heparin, low molecular dextran, nimodipine may produce greater improvements in upper extremity function than Heparin, low molecular dextran, nimodipine.	1	Si et al. 1998

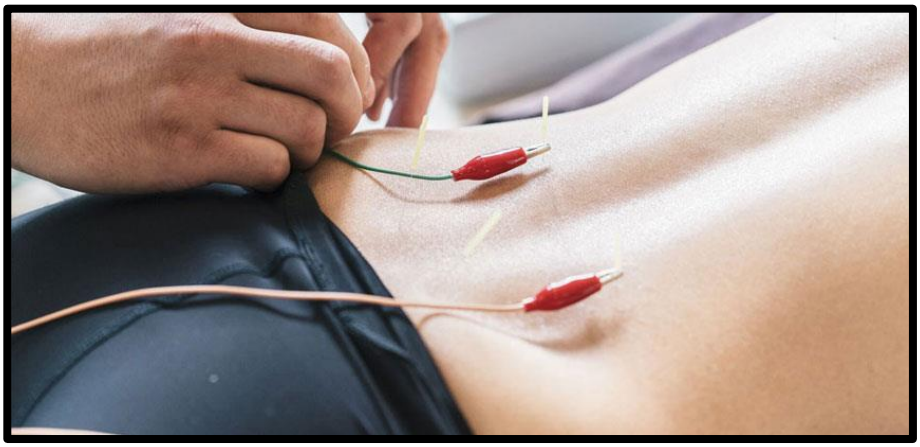
Key Points

- Acupuncture Therapy may be beneficial for improving biomechanical gait measures, biomechanical balance measures, spasticity, neurophysiological measures, gait speed, functional mobility, and balance, but not motor recovery, muscle strength, and activities of daily living, after stroke when compared to Conventional Therapy; the literature is mixed regarding quality of life.
- Acupuncture may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Physiotherapy or Acupuncture with PhysiotherapyNI.
- Contra-lateral Needling (acupuncture on unaffected limbs) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Traditional acupuncture.
- Acupuncture may be beneficial for improving motor recovery, spasticity, range of motion, activities of daily living, gait speed, functional mobility, and balance, but not biomechanical gait measures, pain, gait endurance, and quality of life, after stroke when compared to Sham; the literature is mixed regarding neurophysiological measures.
- Acupuncture Treatment may be beneficial for improving spasticity after stroke when compared to No Treatment; the literature is mixed regarding pain.
- Channel Palpation Guided Acupuncture may not be beneficial for improving motor recovery and quality of life after stroke when compared to Traditional Acupuncture.
- Scalp Acupuncture and Robot Assisted Training may be beneficial for improving motor recovery, biomechanical gait measures, activities of daily living, gait endurance, and balance after stroke when compared to Basic Treatment.
- Scalp Acupuncture may be beneficial for improving motor recovery, muscle strength, neurophysiological measures, activities of daily living, and quality of life after stroke when compared to Conventional Therapy or Other Modalities.
- Auricular Intradermal Acupuncture may be beneficial for improving motor recovery after stroke when compared to Conventional Therapy.
- Acupuncture with Manipulation may be beneficial for improving muscle strength, motor recovery, spasticity, neurophysiological measures, and activities of daily living after stroke when compared to Acupuncture.
- Eye Acupuncture may be beneficial for improving biomechanical gait measures after stroke when compared to Body Acupuncture.
- Multifaceted Alternative Medicine Approaches may be beneficial for improving muscle strength, range of motion, and gait speed, but not quality of life, neurophysiological measures, and aerobic measures, after stroke when compared to Meridian Dredging Exercise; the literature is mixed regarding spasticity, motor recovery, balance, and activities of daily living.

- Neuronavigation-assisted aspiration with electroacupuncture may be beneficial for improving spasticity and activities of daily living, but not motor recovery, after stroke when compared to Neuronavigation-assisted aspiration.
- Neuronavigation-assisted aspiration with electroacupuncture may be beneficial for improving spasticity and activities of daily living, but not motor recovery, after stroke when compared to Electroacupuncture.
- Neuronavigation-assisted aspiration may be beneficial for improving motor recovery and spasticity after stroke when compared to Electroacupuncture; the literature is mixed regarding activities of daily living.
- Electroacupuncture may be beneficial for improving motor recovery, but not spasticity and activities of daily living, after stroke when compared to Conservative therapy.
- Massage and other integrated rehabilitation techniques may be beneficial for improving gait speed, balance, and functional mobility, but not biomechanical gait measures and aerobic measures, after stroke when compared to Health education program; the literature is mixed regarding motor recovery, muscle strength, spasticity, activities of daily living, biomechanical balance measures, and quality of life.
- Chiropractic intervention may not be beneficial for improving neurophysiological measures after stroke when compared to Placebo chiropractic intervention.
- Dry Needling with Conventional Rehabilitation may be beneficial for improving spasticity, range of motion, gait speed, and balance after stroke when compared to Conventional Rehabilitation Alone.
- Acupuncture with Robot-Assisted Gait Training may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Acupuncture Alone.
- Virtual reality-assisted gait adaptation training with acupuncture and conventional physical therapy may be beneficial for improving gait speed and functional mobility, but not biomechanical balance measures and activities of daily living, after stroke when compared to Overground gait adaptation training with acupuncture and conventional physical therapy.
- Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) may be beneficial for improving range of motion, but not balance, after stroke when compared to Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy).
- Joint mobilization with acupuncture may be beneficial for improving activities of daily living, but not pain and gait speed, after stroke when compared to Conventional rehab; the literature is mixed regarding range of motion.
- Joint mobilization with acupuncture may be beneficial for improving range of motion and activities of daily living, but not pain and gait speed, after stroke when compared to Joint mobilization.
- Electroacupuncture with Conventional therapy may be beneficial for improving functional mobility, but not activities of daily living and gait speed, after stroke when compared to Conventional Therapy; the literature is mixed regarding motor recovery.
- One session daily high intensity Videogame exercises with medical massage may result in lesser improvements in aerobic measures when compared to physical therapy with medical massage or 60min/d care and 20min/d massage; the literature is mixed regarding biomechanical balance measures.
- One session daily high intensity Videogame exercises with medical massage may not be beneficial for improving biomechanical balance measures, aerobic measures, and activities of daily living after stroke when compared to two sessions daily high intensity Videogame exercises with medical massage.
- Electroacupuncture, usual care may not be beneficial for improving motor recovery, spasticity, and activities of daily living after stroke when compared to Usual care.
- Unani Medicine (Herbal and Massage) may be beneficial for improving functional mobility after stroke when compared to Western Medicine (Piracetam 800mg).
- Interferential current therapy (ICT) stimulation of gastrocnemius with air-pump massage and rehabilitation may be beneficial for improving spasticity, gait speed, functional mobility, and balance after stroke when compared to Placebo-ICT with air-pump massage and rehabilitation.
- Electroacupuncture with Conventional medication may be beneficial for improving motor recovery and neurophysiological measures after stroke when compared to Conventional medication.

- Electroacupuncture may not be beneficial for improving muscle strength, activities of daily living, and quality of life after stroke when compared to Sham transcutaneous electrical nerve stimulation.
- Electroacupuncture may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Low-intensity, high- frequency electrostimulation (80Hz).
- Electrical Acupuncture with Conventional Therapy may be beneficial for improving motor recovery after stroke when compared to Conventional therapy; the literature is mixed regarding activities of daily living.
- Electroacupuncture with Heparin, low molecular dextran, nimodipine may not be beneficial for improving motor recovery after stroke when compared to Heparin, low molecular dextran, nimodipine.
- One session daily high intensity Videogame exercises with medical massage may be beneficial for improving activities of daily living after stroke when compared to Standard physical therapy with medical massage.
- Two sessions daily high intensity Videogame exercises with medical massage may not be beneficial for improving activities of daily living after stroke when compared to Standard physical therapy with medical massage.
- Traditional acupuncture may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Convenional Care.

Summary of Key Points: Acupuncture and Massage



Intervention	Control(s)	Function domain(s)	Effect
Acupuncture Therapy	Conventional Therapy	Biomechanical gait measures, biomechanical balance measures, spasticity, neurophysiological measures, gait speed, functional mobility, balance	+
Acupuncture Therapy	Conventional Therapy	Motor recovery, muscle strength, activities of daily living	–
Acupuncture Therapy	Conventional Therapy	Quality of life	=
Acupuncture	Physiotherapy or Acupuncture with PhysiotherapyNI	Motor recovery, activities of daily living	–
Contra-lateral Needling (acupuncture on unaffected limbs)	Traditional acupuncture	Motor recovery, activities of daily living	+
Acupuncture	Sham	Motor recovery, spasticity, range of motion, activities of daily living, gait speed, functional mobility, balance	+
Acupuncture	Sham	Biomechanical gait measures, pain, gait endurance, quality of life	–
Acupuncture	Sham	Neurophysiological measures	=
Acupuncture Treatment	No Treatment	Spasticity	+
Acupuncture Treatment	No Treatment	Pain	=
Channel Palpation Guided Acupuncture	Traditional Acupuncture	Motor recovery, quality of life	–
Scalp Acupuncture and Robot Assisted Training	Basic Treatment	Motor recovery, biomechanical gait measures, activities of daily living, gait endurance, balance	+
Scalp Acupuncture	Conventional Therapy or Other Modalities	Motor recovery, muscle strength, neurophysiological measures, activities of daily living, quality of life	+

Auricular Intradermal Acupuncture	Conventional Therapy	Motor recovery	+
Acupuncture with Manipulation	Acupuncture	Muscle strength, motor recovery, spasticity, neurophysiological measures, activities of daily living	+
Acupuncture with Manipulation	Acupuncture	Motor recovery, spasticity, neurophysiological measures, activities of daily living	+
Eye Acupuncture	Body Acupuncture	Biomechanical gait measures	+
Multifaceted Alternative Medicine Approaches	Meridian Dredging Exercise	Muscle strength, range of motion, gait speed	+
Multifaceted Alternative Medicine Approaches	Meridian Dredging Exercise	Quality of life, neurophysiological measures, aerobic measures	−
Multifaceted Alternative Medicine Approaches	Meridian Dredging Exercise	Motor recovery, spasticity, balance, activities of daily living	=
Multifaceted Alternative Medicine Approaches	Meridian Dredging Exercise	Neurophysiological measures, aerobic measures	−
Multifaceted Alternative Medicine Approaches	Meridian Dredging Exercise	Activities of daily living	=
Neuronavigation-assisted aspiration with electroacupuncture	Neuronavigation-assisted aspiration	Spasticity, activities of daily living	+
Neuronavigation-assisted aspiration with electroacupuncture	Neuronavigation-assisted aspiration	Motor recovery	−
Neuronavigation-assisted aspiration with electroacupuncture	Electroacupuncture	Spasticity, activities of daily living	+
Neuronavigation-assisted aspiration	Electroacupuncture	Motor recovery, spasticity	+
Electroacupuncture	Conservative therapy	Motor recovery	+
Electroacupuncture	Conservative therapy	Spasticity, activities of daily living	−
Multifaceted Alternative Medicine Approaches	Meridian Dredging Exercise	Motor recovery	=
Massage and other integrated rehabilitation techniques	Health education program	Gait speed, balance, functional mobility	+
Massage and other integrated rehabilitation techniques	Health education program	Biomechanical gait measures, aerobic measures	−
Massage and other integrated rehabilitation techniques	Health education program	Functional mobility, balance	+
Massage and other integrated rehabilitation techniques	Health education program	Biomechanical balance measures, motor recovery, muscle strength, spasticity, activities of daily living, quality of life	=
Massage and other integrated rehabilitation techniques	Health education program	Balance	+
Massage and other integrated rehabilitation techniques	Health education program	Aerobic measures	−
Chiropractic intervention	Placebo chiropractic intervention	Neurophysiological measures	−

Dry Needling with Conventional Rehabilitation	Conventional Rehabilitation Alone	Spasticity, range of motion, gait speed, balance	+
Acupuncture with Robot-Assisted Gait Training	Acupuncture Alone	Biomechanical gait measures, gait speed, functional mobility	+
Virtual reality-assisted gait adaptation training with acupuncture and conventional physical therapy	Overground gait adaptation training with acupuncture and conventional physical therapy	Gait speed, functional mobility	+
Virtual reality-assisted gait adaptation training with acupuncture and conventional physical therapy	Overground gait adaptation training with acupuncture and conventional physical therapy	Biomechanical balance measures, activities of daily living	–
Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Range of motion	+
Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Balance	–
Joint mobilization with acupuncture	Conventional rehab	Pain, gait speed	–
Joint mobilization with acupuncture	Joint mobilization	Range of motion, activities of daily living	+
Joint mobilization with acupuncture	Joint mobilization	Pain, gait speed	–
Joint mobilization with acupuncture	Conventional rehab	Activities of daily living	+
Electroacupuncture with Conventional therapy	Conventional Therapy	Functional mobility	+
Electroacupuncture with Conventional therapy	Conventional Therapy	Activities of daily living, gait speed	–
One session daily high intensity Videogame exercises with medical massage	physical therapy with medical massage or 60min/d care and 20min/d massage	Aerobic measures	–
One session daily high intensity Videogame exercises with medical massage	physical therapy with medical massage or 60min/d care and 20min/d massage	Biomechanical balance measures	=
One session daily high intensity Videogame exercises with medical massage	two sessions daily high intensity Videogame exercises with medical massage	Biomechanical balance measures, aerobic measures, activities of daily living	–
Electroacupuncture, usual care	Usual care	Motor recovery, spasticity, activities of daily living	–
Unani Medicine (Herbal and Massage)	Western Medicine (Piracetam 800mg)	Functional mobility	+
Interferential current therapy (ICT) stimulation of gastrocnemius with air-pump massage and rehabilitation	Placebo-ICT with air-pump massage and rehabilitation	Spasticity, gait speed, functional mobility, balance	+
Electroacupuncture with Conventional medication	Conventional medication	Motor recovery, neurophysiological measures	+

Electroacupuncture	Sham transcutaneous electrical nerve stimulation	Muscle strength, activities of daily living, quality of life	–
Electroacupuncture with Conventional therapy	Conventional Therapy	Motor recovery	=
Electroacupuncture	Low-intensity, high- frequency electrostimulation (80Hz)	Activities of daily living, gait speed, functional mobility, quality of life	–
Electrical Acupuncture with Conventional Therapy	Conventional therapy	Motor recovery	+
Electrical Acupuncture with Conventional Therapy	Conventional therapy	Activities of daily living	=
Electroacupuncture with Heparin, low molecular dextran, nimodipine	Heparin, low molecular dextran, nimodipine	Motor recovery	–
One session daily high intensity Videogame exercises with medical massage	Standard physical therapy with medical massage	Activities of daily living	+
Two sessions daily high intensity Videogame exercises with medical massage	Standard physical therapy with medical massage	Activities of daily living	–
Traditional acupuncture	Convenional Care	Motor recovery, activities of daily living	+
Neuronavigation-assisted aspiration	Electroacupuncture	Activities of daily living	=
Joint mobilization with acupuncture	Conventional rehab	Range of motion	=
Neuronavigation-assisted aspiration with electroacupuncture	Electroacupuncture	Motor recovery	–

Electroacupuncture and Transcutaneous Electrical Acupoint Stimulation

Adopted from: https://www.promotionhealthcare.com/electroacupuncture-treatment-pain-injuries/

Electroacupuncture is a variant of acupuncture techniques practiced in traditional Chinese medicine, the difference being that a minute electrical current of similar intensity to that of a bioelectric current produced endogenously in the body is applied to the needles used (Wang et al., 2014a). The needle is often placed on meridian points throughout the body (Wang et al., 2014a). Similarly, transcutaneous electrical acupoint stimulation (TEAS) stimulates meridian points believed to be associated with a medical condition with electrical impulses given through needles. The two techniques have very similar mechanisms of action and their influence on afferent stimulation to the body.

A total of eight RCTs were found that evaluated electroacupuncture and transcutaneous electrical acupoint stimulation for lower extremity motor rehabilitation. Five RCTs compared Electroacupuncture Therapy with

Conventional Therapy (Kim et al. 2022c; Cai et al. 2021; Tan et al. 2013; Hsieh et al. 2007; Wong et al. 1999). One RCT compared Electroacupuncture or TEAS with Sham (Hopwood et al. 2008). One RCT compared Electroacupuncture and Low Frequency TENS with High and Low Frequency TENS (Johansson et al. 2001). One RCT compared Electroacupuncture with Heparin with Heparin (Si et al. 1998).

In addition, one RCT in which electroacupuncture and transcutaneous electrical acupoint stimulation formed part of a combined or comparative intervention are cross-referenced at the end of Table 54; their primary listings appear in other tables.

The methodological details and results of all eight RCTs are presented in Table 54.

Table 54. RCTs Evaluating Electroacupuncture and Transcutaneous Electrical Acupoint Stimulation for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
Electroacupuncture vs Conventional Therapy		
Kim et al. (2022c) RCT (8) Nstart=35 Nend=33 TPS=Subacute A vs 0 Also in Table 53 (Acupuncture and Massage)	E: Electroacupuncture + Conventional therapy C: Conventional Therapy Duration: E: 30min/d, 5d/wk, 4 wks C: 120 min/d, 5d/wk, 4wks	E vs C: FMA-LE(-) K-MBI (-) FAC (-) Diffusion Tensor Tractography Fiber Number Affected (-) Fiber Ratio (-) Fractional Anistropy affected (+exp) Fractional Anistropy ratio (+exp) Axial Diffusivity affected (+exp) Axial Diffusivity ratio (+exp)
Cai et al. (2021) RCT (7) Nstart=30 Nend=25 TPS=Subacute A vs 0 Also in Table 53 (Acupuncture and Massage)	E: Electroacupuncture, usual care C: Usual care Duration: 20-30min/session, 3 sessions/wk, for 4wks	E vs C: Modified Ashworth Scale (-) Fugl-Meyer Assessment (-) Barthel Index (-)
Tan et al. (2013) RCT (7) Nstart=63 Nend=61 TPS=Acute A vs 0 Also in Table 53 (Acupuncture and Massage)	E: Electroacupuncture + Conventional medication C: Conventional medication Duration: 20min/d, 6d/wk, for 2wks	E vs C: Fugl Meyer Assessment (+exp) National Institutes of Health Stroke Scale (+exp) Triple stimulation technique amplitude ratio (+exp)
Hsieh et al. (2007) RCT (8) Nstart=63 Nend=54 TPS=Acute A vs 0 Also in Table 53 (Acupuncture and Massage)	E: Electroacupuncture + conventional therapy C: Conventional therapy Duration: 20min/d, 2d/wk for 4wks	E vs C: Fugl-Meyer Assessment (+exp) Lower extremity (-) UE Motor Shoulder elbow (-) Wrist (+exp) Hand (+exp) UE Coordination and speed (-) Functional independence measure (-)

Wong et al. (1999) RCT (4) Nstart=118 Nend=118 TPS=Acute A vs 0 Also in Table 53 (Acupuncture and Massage)	E: Electrical Acupuncture + Conventional Therapy C: Conventional therapy Duration: 30min/d, 5d/wk, for 2wks Electrical Acupuncture, 120min/d, 7d/wk Conventional Therapy	E vs C: Brunnstrom Stage Upper Limb (+exp) Lower Limb (+exp) Functional independence measure (+exp) self-care (+exp) Sphincter (-) Transfer (-) Locomotion (+exp) Communication (-) Social interaction (-) cognition (+exp)
Electroacupuncture or TEAS vs Sham		
Hopwood et al. (2008) RCT (8) Nstart=105 Nend=92 TPS=Acute A vs 0 Also in Table 53 (Acupuncture and Massage)	E: Electroacupuncture C: Sham TENS Duration: 30min/d, 3d/wk for 4wks	E vs C: Motricity Index (-) Barthel Index (-) Nottingham Health Profile: -Pain (-); -Energy level (+exp); -Emotional Reaction (-); -Sleep (-); -Social isolation (-); -Physical Activity (-)
Electroacupuncture vs High and Low Frequency TENS		
Johansson et al. (2001) RCT (8) Nstart=150 Nend=138 TPS=Acute A vs B vs C Also in Table 30 (Transcutaneous Electrical Nerve Stimulation (TENS)); Table 53 (Acupuncture and Massage)	E1: Electroacupuncture E2: High-intensity, low-frequency TENS (80Hz) C: Low-intensity, high-frequency TENS (2Hz) electrostimulation Duration: 30min/d, 2d/wk for 10wks	E1 vs E2 vs C: Rivermead Mobility Index (-) 10-Metre Walk Test (-) Nine Hole Peg Test (-) Barthel Index (-) Nottingham Health Profile (-)
Electroacupuncture with Heparin vs Heparin		
Si et al. (1998) RCT (5) Nstart=42 Nend=42 TPS=Acute A + B vs B Also in Table 53 (Acupuncture and Massage)	E: Electroacupuncture + Heparin, low molecular dextran, nimodipine C: Heparin, low molecular dextran, nimodipine Duration: 30min/d, for 5d electroacupuncture	E vs C: Chinese Stroke Scale (+exp) Level of consciousness (-) Extraocular movements (-) Facial palsy (-) Speech (-) Motor shoulder (+exp) Motor hand (+exp) Motor leg (+exp) Capacity walking (-)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Zhang et al. (2017) RCT (8) Nstart=240 Nend=233 TPS=Acute A + B vs A vs B vs C Primary listing: Table 53 (Acupuncture and Massage)	E1: Neuronavigation-assisted aspiration + electroacupuncture E2: Neuronavigation-assisted aspiration E3: Electroacupuncture C: Conservative therapy Duration: 30min/session, 2sessions/d, for 8wks	E1 vs E2: Fugl-Meyer Assessment (-) Modified Ashworth Scale (+exp1) Barthel Index (+exp1) E1 vs E3: Fugl-Meyer Assessment (-) Modified Ashworth Scale (+exp1) Barthel Index (+exp1)

		E1 vs C: Fugl-Meyer Assessment (+exp1) Modified Ashworth Scale (+exp1) Barthel Index (+exp1) E2 vs E3: Fugl-Meyer Assessment (-) Modified Ashworth Scale (-) Barthel Index (-) E2 vs C: Fugl-Meyer Assessment (+exp2) Modified Ashworth Scale (+exp2) Barthel Index (-) E3 vs C: Fugl-Meyer Assessment (+exp3) Modified Ashworth Scale (+exp2) Barthel Index (-)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed "Feasibility/pilot" in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

1. Body Functions and Structures

MOTOR RECOVERY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	There is conflicting evidence about the effect of Electroacupuncture Therapy when compared to Conventional Therapy for improving motor recovery.	5	Kim et al. 2022c; Cai et al. 2021; Tan et al. 2013; Hsieh et al. 2007; Wong et al. 1999
2	Electroacupuncture with Heparin may not have a difference in efficacy when compared to Heparin for improving motor recovery.	1	Si et al. 1998
1b	Neuronavigation-assisted aspiration with electroacupuncture may not have a difference in efficacy when compared to Neuronavigation-assisted aspiration for improving motor recovery.	1	Zhang et al. 2017
1b	Neuronavigation-assisted aspiration with electroacupuncture may not have a difference in efficacy when compared to Electroacupuncture for improving motor recovery.	1	Zhang et al. 2017
1b	Neuronavigation-assisted aspiration with electroacupuncture may produce greater improvements in motor recovery than Conservative therapy.	1	Zhang et al. 2017
1b	Neuronavigation-assisted aspiration may not have a difference in efficacy when compared to Electroacupuncture for improving motor recovery.	1	Zhang et al. 2017

MUSCLE STRENGTH			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Electroacupuncture or transcutaneous electrical acupoint stimulation may not have a difference in efficacy when compared to Sham for improving muscle strength.	1	Hopwood et al. 2008

SPASTICITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Electroacupuncture Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving spasticity.	1	Cai et al. 2021
1b	Neuronavigation-assisted aspiration with electroacupuncture may produce greater improvements in spasticity than Neuronavigation-assisted aspiration.	1	Zhang et al. 2017

1b	Neuronavigation-assisted aspiration may not have a difference in efficacy when compared to Electroacupuncture for improving spasticity.	1	Zhang et al. 2017

NEUROPHYSIOLOGICAL MEASURES			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Electroacupuncture Therapy may produce greater improvements in neurophysiological measures than Conventional Therapy.	1	Tan et al. 2013

2. Activities

ACTIVITIES OF DAILY LIVING			
LoE	**Conclusion Statement**	**RCTs**	**References**
1a	Electroacupuncture Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving activities of daily living.	3	Cai et al. 2021; Hsieh et al. 2007; Wong et al. 1999
1b	Electroacupuncture or transcutaneous electrical acupoint stimulation may not have a difference in efficacy when compared to Sham for improving activities of daily living.	1	Hopwood et al. 2008
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high- frequency electrostimulation (80Hz) for improving activities of daily living.	1	Johansson et al. 2001
1b	Neuronavigation-assisted aspiration with electroacupuncture may produce greater improvements in activities of daily living than Neuronavigation-assisted aspiration.	1	Zhang et al. 2017
1b	Neuronavigation-assisted aspiration with electroacupuncture may produce greater improvements in activities of daily living than Electroacupuncture.	1	Zhang et al. 2017
1b	There is conflicting evidence about the effect of Neuronavigation-assisted aspiration with electroacupuncture when compared to Conservative therapy for improving activities of daily living.	1	Zhang et al. 2017
1b	Neuronavigation-assisted aspiration may not have a difference in efficacy when compared to Electroacupuncture for improving activities of daily living.	1	Zhang et al. 2017

GAIT SPEED			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Electroacupuncture Therapy may not have a difference in efficacy when compared to Conventional Therapy for improving gait speed.	1	Hsieh et al. 2007
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high- frequency electrostimulation (80Hz) for improving gait speed.	1	Johansson et al. 2001

FUNCTIONAL MOBILITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Electroacupuncture Therapy may produce greater improvements in functional mobility than Conventional Therapy.	1	Kim et al. 2022c
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high- frequency electrostimulation (80Hz) for improving functional mobility.	1	Johansson et al. 2001

3. Participation

QUALITY OF LIFE			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Electroacupuncture or transcutaneous electrical acupoint stimulation may not have a difference in efficacy when compared to Sham for improving quality of life.	1	Hopwood et al. 2008
1b	Electroacupuncture may not have a difference in efficacy when compared to Low-intensity, high- frequency electrostimulation (80Hz) for improving quality of life.	1	Johansson et al. 2001

Other Associated Outcome Measures

FATIGUE AND SLEEP			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Electroacupuncture or transcutaneous electrical acupoint stimulation may not have a difference in efficacy when compared to Sham for improving fatigue and sleep.	1	Hopwood et al. 2008

UPPER EXTREMITY			
LoE	**Conclusion Statement**	**RCTs**	**References**
1b	Electroacupuncture Therapy may produce greater improvements in upper extremity function than Conventional Therapy.	2	Hsieh et al. 2007; Wong et al. 1999
2	Electroacupuncture with Heparin may produce greater improvements in upper extremity function than Heparin.	1	Si et al. 1998

Key Points

- Electroacupuncture Therapy may be beneficial for improving neurophysiological measures and functional mobility, but not spasticity, activities of daily living, and gait speed, after stroke when compared to Conventional Therapy; the literature is mixed regarding motor recovery.
- Electroacupuncture or transcutaneous electrical acupoint stimulation may not be beneficial for improving muscle strength, activities of daily living, and quality of life after stroke when compared to Sham.

- Electroacupuncture may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Low-intensity, high- frequency electrostimulation (80Hz).
- Electroacupuncture with Heparin may not be beneficial for improving motor recovery after stroke when compared to Heparin.
- Neuronavigation-assisted aspiration with electroacupuncture may be beneficial for improving spasticity and activities of daily living, but not motor recovery, after stroke when compared to Neuronavigation-assisted aspiration.
- Neuronavigation-assisted aspiration with electroacupuncture may be beneficial for improving spasticity and activities of daily living, but not motor recovery, after stroke when compared to Electroacupuncture.
- Neuronavigation-assisted aspiration with electroacupuncture may be beneficial for improving motor recovery and spasticity after stroke when compared to Conservative therapy; the literature is mixed regarding activities of daily living.
- Neuronavigation-assisted aspiration may not be beneficial for improving motor recovery, spasticity, and activities of daily living after stroke when compared to Electroacupuncture.

Summary of Key Points: Electroacupuncture and Transcutaneous Electrical Acupoint Stimulation

Intervention	Control(s)	Function domain(s)	Effect
Electroacupuncture Therapy	Conventional Therapy	Neurophysiological measures, functional mobility	+
Electroacupuncture Therapy	Conventional Therapy	Spasticity, activities of daily living, gait speed	–
Electroacupuncture Therapy	Conventional Therapy	Motor recovery	=
Electroacupuncture or transcutaneous electrical acupoint stimulation	Sham	Muscle strength, activities of daily living, quality of life	–
Electroacupuncture	Low-intensity, high- frequency electrostimulation (80Hz)	Activities of daily living, gait speed, functional mobility, quality of life	–
Electroacupuncture with Heparin	Heparin	Motor recovery	–
Neuronavigation-assisted aspiration with electroacupuncture	Neuronavigation-assisted aspiration	Spasticity, activities of daily living	+
Neuronavigation-assisted aspiration with electroacupuncture	Neuronavigation-assisted aspiration	Motor recovery	–
Neuronavigation-assisted aspiration with electroacupuncture	Electroacupuncture	Spasticity, activities of daily living	+
Neuronavigation-assisted aspiration with electroacupuncture	Electroacupuncture	Motor recovery	–
Neuronavigation-assisted aspiration with electroacupuncture	Conservative therapy	Motor recovery, spasticity	+
Neuronavigation-assisted aspiration	Electroacupuncture	Motor recovery, spasticity, activities of daily living	–
Neuronavigation-assisted aspiration with electroacupuncture	Conservative therapy	Activities of daily living	=

Traditional Herbal Medicines

Adopted from: https://drmeelainling.com/herbs-diet/

Traditional Chinese, Japanese and Indian herbal medicine are complementary and alternative forms of medicine that have been utilized as a healthcare system in Asian countries for hundreds of years and are widely used for stroke treatment today (Han et al., 2017; Tsai et al., 2017). Different herbal medicines have various beneficial properties such as anti-inflammatory, increasing cerebral blood flow velocity, inhibiting platelet aggregation, increasing tissue tolerance to hypoxia, etc. (Han et al., 2017). Chinese and Japanese herbal medicines commonly used for stroke rehabilitation generally consist of a mixture of different plant and animal extracts with these varying properties (Han et al., 2017).

A total of eight RCTs were found that evaluated traditional herbal medicines for lower extremity motor rehabilitation. One RCT compared NeuroAid with Placebo (Kong et al. 2009). Five RCTs compared Other Herbal Medications with Placebo or No Medication (Ling et al. 2022; Tang et al. 2021; Ahmed et al. 2015; Zhu et al. 2014; Goto et al. 2011). One RCT compared Other Herbal Medications with Conventional Therapy (Wang et al. 2020b). One RCT compared Other Herbal Medications with Fluoxetine vs Placebo (Gong et al. 2020).

In addition, one RCT in which traditional herbal medicines formed part of a combined or comparative intervention are cross-referenced at the end of Table 55; their primary listings appear in other tables.

The methodological details and results of all eight RCTs are presented in Table 55.

Table 55. RCTs Evaluating Traditional Herbal Medicines for Lower Extremity Motor Rehabilitation

Authors (Year) **Study Design (PEDro Score)** **Sample Size start/end** **Time post stroke category** **Study design**	**Interventions** **Duration: Session length, frequency per week for total number of weeks**	**Outcome Measures** **Result (direction of effect)**
NeuroAid vs Placebo		
Kong et al. (2009) RCT (7) Nstart=40 Nend=33 TPS=Acute A vs 0	E: NeuroAid (Amount Not Specified) C: Placebo (Amount Not Specified) Duration: 4 capsules, 3x/d, for 4wks	E vs C: Fugl-Meyer Assessment (-) Functional Independence Measure (-) NIH Stroke Scale (-)

Other Herbal Medications vs Placebo or No Medication		
Ling et al. (2022) RCT (8) Nstart=120 Nend=117 TPS=Subacute A vs 0	E: Ruyi Zhenbao Pills C: Placebo Ruyi Zhenbao Pills Duration: 2g, 2 times a day, 4 weeks	E vs C: FMA motion (+exp) sensory (-) Berg balance scale (+exp) Modified barthel index (-) Special Scale of the Quality of Life (-) Visual analogue scale (-)
Tang et al. (2021) RCT (9) Nstart=622 Nend=529 TPS=Acute A vs B vs 0	E1: Qizhitongluo (500mg capsules) taken at breakfast and dinner + Placebo taken after lunch E2: Naoxintong (400mg capsules) taken after each meal C: Placebo capsule Duration: Qizhitongluo: 4,-500mg capsules, 2x/d + 4 placebo capsules 1x/d, for 12wks Naoxintong: 4,- 400mg capsules 3doses/d, for 12wks Placebo: 4 placebo capsules 3x/d, for 12wks	E1 vs C: Fugl-Meyer Assessment Lower Limb (+exp1) Fugl-Meyer Assessment Upper Limb (+exp1) Aphasia Quotient (+exp1) Barthel Index (+exp1) TCM syndrome score (+exp1) Plasma glucose (-) Serum lipid level (-) Coagulation (-) E1 vs E2: Fugl-Meyer Assessment Lower Limb (+exp) Fugl-Meyer Assessment Upper Limb (+exp1) Aphasia Quotient (+exp1) Barthel Index (-) TCM syndrome score (+exp1) Plasma glucose (-) Serum lipid level (-) Coagulation (-) E2 vs C: Fugl-Meyer Assessment Lower Limb (-) Fugl-Meyer Assessment Upper Limb (-) Aphasia Quotient (-) Barthel Index (-) TCM syndrome score (-) Plasma glucose (-) Serum lipid level (-) Coagulation (-)
Ahmed et al. (2015) RCT (5) Nstart=40 Nend=40 TPS=Chronic A vs B Also in Table 53 (Acupuncture and Massage)	E: Unani Medicine (Herbal and Massage) C: Western Medicine (Piracetam 800mg) Duration: 1dose/d, for 4wks medications & 15min/d, for 2wks massage	E vs C: Stroke Rehabilitation Assessment of Movement (+exp)
Zhu et al. (2014) RCT (5) Nstart=60 Nend=60 TPS=Acute	E: Shaoyao Gancao (10mL) + Physiotherapy C: No medication + Physiotherapy Duration: 10mL of Shaoyoo Gancoo (3doses/d) for 4wks & 30min/d, 6d/wk, for 4wks physiotherapy	E vs C: Modified Ashworth Scale (+exp) Composite Spasticity Scale (+exp) Fugl-Meyer Assessment (+exp) Barthel Index (+exp)

A vs B		Integrated electromyography of all muscles (+exp)
Goto et al. (2011) RCT (6) Nstart=31 Nend=30 TPS=Chronic A vs B	E: Tokishakuyakusan (2.5g) C: No medication Duration: 2.5g of Tokishakuyakusan (3x/d) for 1yr	E vs C: Stroke Impairment Assessment Scale (+exp) Functional Independence Measure (+exp)
Other Herbal Medications vs Conventional Therapy		
Wang et al. (2020b) RCT (6) Nstart=444 Nend=403 TPS=Subacute A vs 0	E: Tibetan medicated bathing therapy + conventional rehabilitation C: Conventional rehabilitation Duration: 150min/d, 5d/wk, 4wks conventional rehabilitation & 60min/d, 5d/wk, 4wks Tibetan medicated bathing	E vs C: Modified Ashworth Scale Elbow flexors (+exp) Wrist flexors (+exp) Finger flexors (-) Knee extensors (-) Ankle plantar flexors (+exp) Fugl-Meyer Assessment (+exp) Upper limb(+exp) Lower limb (-) Modified Barthel Index (+exp)
Other Herbal Medications vs Fluoxetine vs Placebo		
Gong et al. (2020) RCT (7) Nstart=254 Nend=222 TPS=Acute A1 vs B vs A2 vs 0 Also in Table 40 (Antidepressants)	E1: Shu-Gan-Jie-Yu capsule, 720 mg E2: Fluoxetine, 20 mg PO daily E3: Shu-Gan-Jie-Yu (2160 mg daily) C: Placebo Duration: E1: 720 mg, 3/d, 7d/wk, 12wks (2160 mg daily) Shu-Gan- Jie-Yu; E2: 20mg 1/d, 7d/wk, for 12wks fluoxetine; E3: 720 mg, 3/d, 7d/wk, for 12wks (2160 mg daily) Shu-Gan-Jie-Yu + 20mg 1/d, 7d/wk, for 12wks fluoxetine	E1/E2/E3 vs C: Modified Rankin Scale (+exp1, +exp2, +exp3) Fugl-Meyer Motor (+exp1, +exp2, +exp3)
Cross-Referenced RCTs: Combined or Comparative Interventions		
Na et al. (2018) RCT (6) Nstart=76 Nend=76 TPS=Acute A + B vs 0 Primary listing: Table 53 (Acupuncture and Massage)	E: Chinese Traditional therapy (Bath in Chinese herbal medicine + Acupuncture with massage) + Conventional care C: Conventional care Duration: 1session/d, 7d/wk for 4wks - Chinese Traditional therapy (30min/d Traditional bath therapy + 30min/d Acupuncture and Massage); 40min/d for 4wks conventional care	E vs C: Fugl-Meyer assessment (+exp) Modified Barthel index (+exp) Neurological impairments (+exp) Efficacy of treatment (+exp)

Abbreviations and table notes: C=control group; D=days; E=experimental group; H=hours; Min=minutes; RCT=randomized controlled trial; Feasibility/pilot RCT=study typed “Feasibility/pilot” in the source workbook; TPS=time post stroke category (Acute: less than 30 days, Subacute: more than 1 month but less than 6 months, Chronic: over 6 months); Wk=weeks.

+exp indicates a statistically significant between groups difference at α=0.05 in favour of the experimental group

+exp1/+exp2/+exp3 indicates a statistically significant between groups difference at α=0.05 in favour of the first, second or third experimental group

+con indicates a statistically significant between groups difference at α=0.05 in favour of the control group

- indicates no statistically significant between groups differences at α=0.05

no stats / no between-group stat indicates the study did not report a between groups comparison for that outcome

Key Points

- NeuroAid may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Other Herbal Medications may be beneficial for improving motor recovery, spasticity, activities of daily living, functional mobility, and balance, but not neurophysiological measures and quality of life, after stroke when compared to Placebo or No Medication.
- Qizhitongluo (500mg capsules) taken at breakfast and dinner with Placebo taken after lunch may be beneficial for improving motor recovery, but not neurophysiological measures, after stroke when

compared to Naoxintong (400mg capsules) taken after each meal; the literature is mixed regarding activities of daily living.

- Other Herbal Medications may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional Therapy; the literature is mixed regarding spasticity.
- Chinese Traditional therapy (Bath in Chinese herbal medicine with Acupuncture with massage) and Conventional care may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional care.
- Fluoxetine (20 mg) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Shu-Gan-Jie-Yu (2160 mg daily) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Shu-Gan-Jie-Yu capsule (720 mg) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.

Summary of Key Points: Traditional Herbal Medicines

Intervention	Control(s)	Function domain(s)	Effect
NeuroAid	Placebo	Motor recovery, activities of daily living	–
Other Herbal Medications	Placebo or No Medication	Motor recovery, spasticity, activities of daily living, functional mobility, balance	+
Other Herbal Medications	Placebo or No Medication	Neurophysiological measures, quality of life	–
Qizhitongluo (500mg capsules) taken at breakfast and dinner with Placebo taken after lunch	Naoxintong (400mg capsules) taken after each meal	Motor recovery	+
Qizhitongluo (500mg capsules) taken at breakfast and dinner with Placebo taken after lunch	Naoxintong (400mg capsules) taken after each meal	Neurophysiological measures	–

Other Herbal Medications	Conventional Therapy	Motor recovery, activities of daily living	+
Other Herbal Medications	Conventional Therapy	Spasticity	=
Chinese Traditional therapy (Bath in Chinese herbal medicine with Acupuncture with massage) and Conventional care	Conventional care	Motor recovery, activities of daily living	+
Fluoxetine (20 mg)	Placebo	Motor recovery, activities of daily living	+
Shu-Gan-Jie-Yu (2160 mg daily)	Placebo	Motor recovery, activities of daily living	+
Shu-Gan-Jie-Yu capsule (720 mg)	Placebo	Motor recovery, activities of daily living	+

Appendix A: Key Points

This appendix compiles the Key Points from all 55 intervention categories (Tables 1–55).

A.1 Neurodevelopmental Techniques and Motor Relearning (Table 1)

Key Points

- Bobath Concept Approach may be beneficial for improving spasticity, activities of daily living, balance, and quality of life, but not motor recovery and biomechanical gait measures, after stroke when compared to Conventional Therapies; the literature is mixed regarding gait speed and functional mobility.
- Early Bobath Approaches may be beneficial for improving functional mobility and balance after stroke when compared to Late Bobath Approaches.
- Bobath Concept Approach with Task-Specific Training may be beneficial for improving gait speed, but not biomechanical balance measures, activities of daily living, gait endurance, and balance, after stroke when compared to Task-Specific Training.
- Motor Relearning Programmes may be beneficial for improving biomechanical balance measures, activities of daily living, and balance, but not functional mobility, after stroke when compared to Conventional Therapy or Sham.
- Motor relearning with lower limb force-feedback may be beneficial for improving gait speed and gait endurance, but not motor recovery and functional mobility, after stroke when compared to Motor relearning with upper limb force-feedback.
- Motor Relearning may not be beneficial for improving motor recovery, spasticity, sensory and proprioceptive function, activities of daily living, gait endurance, functional mobility, and quality of life after stroke when compared to Bobath Concept Approach.
- Neurodevelopmental Bobath Concept Approach may be beneficial for improving biomechanical gait measures after stroke when compared to proprioceptive neuromuscular facilitation method (proprioceptive neuromuscular facilitation).
- Bobath Concept Approach Combined with Other Therapies may be beneficial for improving range of motion and balance, but not functional mobility, after stroke when compared to Bobath or Conventional Therapy.
- Bobath Concept Approach may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, muscle strength, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Task-Specific Training.
- Functional (adaptive) movement approach may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to functional approach for lower limb dressing.
- Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and functional mobility, but not balance and falls and fear of falling, after stroke when compared to Balance exercises with neurodevelopmental treatment.
- Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and functional mobility, but not balance and falls and fear of falling, after stroke when compared to gaze stabilization exercises with neurodevelopmental treatment.
- Cervical mobilization with Bobath neurodevelopmental therapy may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and functional mobility after stroke when compared to Sham spinal mobilization with Bobath neurodevelopmental therapy.
- Sustained natural apophyseal glides with neurodevelopmental techniques may not be beneficial for improving biomechanical balance measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Maitland mobilization with neurodevelopmental techniques.
- Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) may be beneficial for improving range of motion, but not balance, after stroke when compared to Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent

pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy).

- Sensory training with Trunk-centred Bobath exercise may be beneficial for improving sensory and proprioceptive function, but not activities of daily living, gait endurance, and balance, after stroke when compared to Trunk-centred Bobath exercise.
- Motor Relearning Program with Obstacle walking may be beneficial for improving spasticity and functional mobility after stroke when compared to Motor Relearning Program.
- Whole body vibration with Neurodevelopmental treatment may be beneficial for improving gait endurance, but not neurophysiological measures and aerobic measures, after stroke when compared to Neurodevelopmental treatment.
- Repetitive transcranial magnetic stimulation with Motor relearning procedure may be beneficial for improving motor recovery, spasticity, and neurophysiological measures, but not functional mobility, after stroke when compared to Motor relearning procedure with Conventional rehabilitation.
- Dry needling with Neurodevelopmental therapy may be beneficial for improving range of motion, gait speed, and balance after stroke when compared to Neurodevelopmental therapy; the literature is mixed regarding spasticity.
- Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques may be beneficial for improving muscle strength, gait speed, functional mobility, and balance after stroke when compared to Talocrural joint only mobilization with neurodevelopmental techniques.
- Inspiratory Muscle Training with Neurodevelopmental Bobath Treatment may not be beneficial for improving aerobic measures, gait endurance, and functional mobility after stroke when compared to Neurodevelopmental Bobath Treatment; the literature is mixed regarding balance.
- Muscle strengthening training to non-paralytic dorsiflexion muscles with neurodevelopmental therapy may not be beneficial for improving neurophysiological measures, gait speed, and functional mobility after stroke when compared to Muscle strengthening training to paralytic dorsiflexion muscles with neurodevelopmental therapy.
- Matrix Rhythm Therapy (vibration) from thoracic spine to lower extremity with Bobath Therapy may be beneficial for improving spasticity, range of motion, gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Bobath Therapy.
- Segmental mid-thoracic mobilization with neurodevelopmental therapy may be beneficial for improving quality of life, but not biomechanical balance measures and aerobic measures, after stroke when compared to Foam roller exercises with neurodevelopmental therapy.
- Modified constraint-induced movement therapy with Neurodevelopmental therapy may be beneficial for improving muscle strength, but not quality of life, after stroke when compared to neurodevelopmental therapy.
- Bobath with dry needling may be beneficial for improving motor recovery, biomechanical balance measures, and spasticity after stroke when compared to Bobath.
- Action observation of community ambulation with Functional training based on neurodevelopmental techniques may be beneficial for improving gait speed, functional mobility, and falls and fear of falling, but not biomechanical gait measures, after stroke when compared to Landscape observation with Functional training based on neurodevelopmental techniques.
- Gait training with Rhythmic auditory stimulation and conventional therapy (bobath) may be beneficial for improving biomechanical balance measures, but not biomechanical gait measures and gait speed, after stroke when compared to Gait training with conventional therapy (bobath).
- Cyclic neuromuscular electrical stimulation with Bobath may be beneficial for improving muscle strength, spasticity, and range of motion, but not neurophysiological measures, after stroke when compared to Bobath Approach.
- Body weight supported Treadmill with Bobath physiotherapy may be beneficial for improving gait speed and gait endurance, but not motor recovery and functional mobility, after stroke when compared to Bobath physiotherapy.
- Musical motor feedback with Conventional gait therapy and Neurodevelopmental therapy may not be beneficial for improving gait speed after stroke when compared to Conventional gait therapy with Neurodevelopmental therapy; the literature is mixed regarding biomechanical gait measures.

- Motor relearning with electromyography biofeedback may not be beneficial for improving range of motion, neurophysiological measures, and gait speed after stroke when compared to Motor relearning.

A.2 Sit-to-Stand Training (Table 2)

Key Points

- Sit-to-Stand Training may be beneficial for improving muscle strength, but not biomechanical balance measures, spasticity, functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy; the literature is mixed regarding activities of daily living.
- Sit-to-Stand Training (with Swiss ball) may be beneficial for improving motor recovery and biomechanical balance measures, but not functional mobility, after stroke when compared to Sit-to-stand Training (with stool).
- Unstable Sit-to-Stand Support Surface may be beneficial for improving biomechanical gait measures, but not gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Stable Sit-to-Stand Support Surface.
- Sit-to-stand Training with Asymmetrical Foot Position may be beneficial for improving functional mobility and balance after stroke when compared to Sit-to-stand Training with Symmetrical Foot Position.
- Continuous Auditory Feedback During Sit-to-Stand Training may be beneficial for improving motor recovery, biomechanical balance measures, and functional mobility, but not activities of daily living, after stroke when compared to No Feedback During Sit-to- stand Training.
- Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy may be beneficial for improving muscle strength, gait speed, functional mobility, balance, and quality of life after stroke when compared to Sit to Stand Training with physiotherapy.
- Sit-to-Stand training with Visual Feedback may not be beneficial for improving functional mobility after stroke when compared to Sit-to-stand Training with physiotherapy; the literature is mixed regarding biomechanical balance measures.
- Modified Sit-to-Stand Training may be beneficial for improving functional mobility and balance after stroke when compared to Conventional Therapy.
- Standing postural symmetry training with a visual and auditory biofeedback trainer with repetitive sit-to-stand training and conventional rehabilitation may not be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Conventional rehabilitation.
- Sit-to-Stand training combined with transcutaneous electrical nerve stimulation may be beneficial for improving biomechanical balance measures and spasticity, but not muscle strength, after stroke when compared to Sit-to-Stand Training.
- Intensive Sit-to-Stand Training may be beneficial for improving functional mobility, but not activities of daily living, after stroke when compared to Regular Sit-to-Stand Training; the literature is mixed regarding muscle strength.
- Lateral Weight Transference Exercises in Sitting and Standing may not be beneficial for improving functional mobility and balance after stroke when compared to Conventional Care.

A.3 Wheelchair Use (Table 3)

Key Points

- The literature is mixed regarding the effect of Neater Uni-Wheelchair Attachment on activities of daily living after stroke when compared to Wheelchair.
- Encouraging Self-Propulsion may not be beneficial for improving spasticity, activities of daily living, and gait speed after stroke when compared to Discouraging Self-Propulsion.

A.4 Trunk Training (Table 4)

Key Points

- Trunk Training may be beneficial for improving motor recovery, biomechanical balance measures, gait speed, functional mobility, and balance, but not biomechanical gait measures, muscle strength, range of motion, activities of daily living, gait endurance, and quality of life, after stroke when compared to Conventional Therapy.
- Trunk stabilization exercise using weights with general physiotherapy may be beneficial for improving biomechanical balance measures, gait speed, functional mobility, and balance after stroke when compared to Trunk stabilization without weights with general physiotherapy.
- Trunk Training with Physio Equipment may be beneficial for improving biomechanical balance measures and gait endurance, but not biomechanical gait measures and gait speed, after stroke when compared to Trunk stabilization exercises with conventional physical exercise; the literature is mixed regarding functional mobility and balance.
- Trunk stabilization exercise with Pelvic compression belt on paretic side and comprehensive rehabilitation therapy may be beneficial for improving biomechanical gait measures, gait speed, and gait endurance, but not balance, after stroke when compared to Trunk stabilization exercise with Pelvic compression belt on non- paretic side and comprehensive rehabilitation therapy.
- Segmental mid-thoracic mobilization with neurodevelopmental therapy may be beneficial for improving quality of life, but not biomechanical balance measures and aerobic measures, after stroke when compared to Foam roller exercises with neurodevelopmental therapy.
- Trunk Training with Tilted Platforms may be beneficial for improving sensory and proprioceptive function, activities of daily living, and balance, but not motor recovery, after stroke when compared to Trunk Training with Horizontal Platforms.
- Trunk Exercise with Unstable Surface may be beneficial for improving biomechanical balance measures, muscle strength, gait speed, gait endurance, balance, and falls and fear of falling, but not motor recovery, sensory and proprioceptive function, and functional mobility, after stroke when compared to Trunk Exercise with Stable Surface or conventional therapy.
- Core stability training on stable surface may not be beneficial for improving biomechanical balance measures, muscle strength, balance, and falls and fear of falling after stroke when compared to Core stability training on unstable surface.
- Stable trunk training with plinth may not be beneficial for improving activities of daily living, gait speed, functional mobility, balance, and quality of life after stroke when compared to Unstable trunk training with Swiss ball.
- Trunk Training Combined with Robotics may be beneficial for improving motor recovery, biomechanical balance measures, muscle strength, and balance after stroke when compared to Conventional Therapy; the literature is mixed regarding biomechanical gait measures and functional mobility.
- Trunk Training Combined with Dual-Task Training may be beneficial for improving gait speed, functional mobility, balance, and quality of life after stroke when compared to Trunk Training.
- Trunk Training may be beneficial for improving gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Cognitive Training.
- Dynamic Neuromuscular Stabilization may be beneficial for improving range of motion and functional mobility, but not biomechanical gait measures, balance, and falls and fear of falling, after stroke when compared to Conventional Core Exercises; the literature is mixed regarding muscle strength.
- Trunk Training with Visual or Auditory Feedback may be beneficial for improving biomechanical gait measures, gait speed, functional mobility, balance, and falls and fear of falling, but not spasticity and activities of daily living, after stroke when compared to Conventional Therapy; the literature is mixed regarding muscle strength.
- Trunk Training with Balance Training and transcutaneous electrical nerve stimulation may be beneficial for improving sensory and proprioceptive function, but not balance, after stroke when compared to Treadmill Training and Placebo transcutaneous electrical nerve stimulation.

- Different Trunk Muscle Activation Exercises Compared to Each other may be beneficial for improving balance after stroke when compared to Bobath based trunk training with Conventional therapy; the literature is mixed regarding neurophysiological measures.
- Trunk stabilization exercise with abdominal hallowing with Conventional rehabilitation program may not be beneficial for improving gait speed, balance, and functional mobility after stroke when compared to Trunk stabilization exercise with bracing maneuver with Conventional rehabilitation program.
- Trunk Training with Delayed may not be beneficial for improving motor recovery, neurophysiological measures, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Real-Time Visual Feedback.
- Kneeling Training may be beneficial for improving balance, but not motor recovery, biomechanical gait measures, and range of motion, after stroke when compared to Treadmill Training.
- Bobath with Core stability training may be beneficial for improving balance after stroke when compared to Conventional physical therapy.
- Metronome training with core strengthening and general balance exercises may be beneficial for improving functional mobility after stroke when compared to Core strengthening with general balance exercises.
- Core muscle training with Functional electrical stimulation may be beneficial for improving muscle strength, gait speed, and balance after stroke when compared to Core muscle training; the literature is mixed regarding functional mobility.
- Sensory training with Trunk-centred Bobath exercise may be beneficial for improving sensory and proprioceptive function, but not activities of daily living, gait endurance, and balance, after stroke when compared to Trunk-centred Bobath exercise.
- Space Balance 3D system for active trunk training with conventional physical and occupational therapy may be beneficial for improving muscle strength and balance after stroke when compared to General trunk training with Conventional physical and occupational physiotherapy.
- Trunk rehabilitation with Kinesio taping may not be beneficial for improving biomechanical balance measures after stroke when compared to Trunk rehabilitation with Placebo taping.
- Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit) may be beneficial for improving balance, but not biomechanical gait measures, after stroke when compared to Trunk stabilization exercises; the literature is mixed regarding muscle strength.
- Smartphone visual feedback for trunk control training with Conventional care may be beneficial for improving functional mobility and balance after stroke when compared to Conventional care.
- Trunk neuromuscular electrical stimulation with Core muscle training may not be beneficial for improving activities of daily living after stroke when compared to Core Training; the literature is mixed regarding balance.
- Trunk neuromuscular electrical stimulation with Core muscle training may not be beneficial for improving activities of daily living and balance after stroke when compared to Trunk neuromuscular electrical stimulation.
- Core stability exercises with real time feedback and conventional physical therapy may be beneficial for improving gait speed and functional mobility, but not biomechanical gait measures, after stroke when compared to Core stability exercises with conventional physical therapy.
- Core stability training on stable surface may be beneficial for improving biomechanical balance measures, muscle strength, balance, and falls and fear of falling after stroke when compared to Individualized physiotherapy.
- Stable trunk training with plinth may be beneficial for improving activities of daily living, gait speed, balance, and quality of life after stroke when compared to Standard physiotherapy.
- Unstable trunk training with Swiss ball may be beneficial for improving activities of daily living, gait speed, balance, and quality of life after stroke when compared to Standard physiotherapy.
- Trunk stabilization exercise with Pelvic compression belt on paretic side with comprehensive rehabilitation therapy may not be beneficial for improving balance after stroke when compared to Trunk stabilization exercise with Pelvic compression belt on non- paretic side with comprehensive rehabilitation therapy.
- Aquatic therapy (Halliwick, Watsu, and Trunk Training) may not be beneficial for improving gait speed after stroke when compared to Trunk control exercises; Aquatic therapy (Halliwick, Watsu, and Trunk

Training) may result in lesser improvements in biomechanical gait measures when compared to Trunk control exercises.

A.5 Task-Specific Training (Table 5)

Key Points

- Task-Specific Training may be beneficial for improving biomechanical gait measures, gait speed, and gait endurance, but not motor recovery and balance, after stroke when compared to Conventional Therapy; the literature is mixed regarding biomechanical balance measures, activities of daily living, and functional mobility.
- Task oriented training with altered sensory input may be beneficial for improving balance, but not biomechanical balance measures, after stroke when compared to Conventional physical therapy; the literature is mixed regarding falls and fear of falling and functional mobility.
- Task Oriented sitting Reach Training may be beneficial for improving biomechanical gait measures and balance, but not gait speed, after stroke when compared to Sham Training.
- Task Specific Treadmill Training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill Training.
- Task-Oriented Training may not be beneficial for improving functional mobility and balance after stroke when compared to Speed Dependent Treadmill Training.
- Task Oriented Resistance Training may be beneficial for improving biomechanical gait measures, muscle strength, gait speed, gait endurance, and functional mobility after stroke when compared to No Treatment.
- Task Oriented Gait Training may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility, but not activities of daily living and balance, after stroke when compared to Conventional Training.
- Task oriented circuit gait training may be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Strength training of lower extremities.
- Task Specific Circuit Training may not be beneficial for improving motor recovery, muscle strength, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Conventional/Sham.
- Lower extremity task- specific rehabilitation may be beneficial for improving gait speed, but not balance, after stroke when compared to Upper extremity task- specific rehabilitation.
- Task Oriented Leg Training may not be beneficial for improving activities of daily living and gait endurance after stroke when compared to Body Weight Support Training; the literature is mixed regarding functional mobility.
- Activity Repetition Training may be beneficial for improving functional mobility and balance after stroke when compared to Task Oriented Training.
- Early supported discharge to Day unit focussed on task- oriented training may not be beneficial for improving activities of daily living, functional mobility, and balance after stroke when compared to Traditional treatment.
- Task Specific Training Combined with Other Therapies may be beneficial for improving motor recovery, spasticity, range of motion, activities of daily living, gait endurance, functional mobility, and balance, but not biomechanical gait measures and muscle strength, after stroke when compared to Task Specific Therapy; the literature is mixed regarding biomechanical balance measures and gait speed.
- Task-oriented training with Abdominal drawing-in maneuver may be beneficial for improving biomechanical balance measures, activities of daily living, and balance after stroke when compared to Task-oriented training.
- Task-specific training with cognitive sensorimotor exercise may be beneficial for improving sensory and proprioceptive function, but not spasticity and gait speed, after stroke when compared to Task-specific training with conventional physical therapy.
- Lower body may be beneficial for improving gait endurance and functional mobility after stroke when compared to Upper Body Task Specific Training; the literature is mixed regarding gait speed.

- High Intensity Task-Specific Training may be beneficial for improving gait speed and gait endurance, but not balance, after stroke when compared to Low Intensity Training or Conventional Therapy.
- Task Oriented Training with Tilt Table may be beneficial for improving motor recovery, range of motion, and activities of daily living after stroke when compared to Tilt Table Alone.
- Tilt table one-leg standing training with Conventional rehabilitation may not be beneficial for improving gait speed after stroke when compared to Tilt table progressive task- oriented training with Conventional rehabilitation; the literature is mixed regarding biomechanical gait measures; Tilt table one-leg standing training with Conventional rehabilitation may result in lesser improvements in muscle strength when compared to Tilt table progressive task- oriented training with Conventional rehabilitation.
- Task-Specific Circuit Training may not be beneficial for improving gait speed and functional mobility after stroke when compared to Group Activities; the literature is mixed regarding gait endurance.
- Task-specific training may be beneficial for improving spasticity, functional mobility, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Group Task-Oriented Circuit Training may not be beneficial for improving muscle strength, spasticity, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Conventional Training.
- Task-related Training combined with transcutaneous electrical nerve stimulation may be beneficial for improving balance, but not gait endurance and quality of life, after stroke when compared to C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy; the literature is mixed regarding functional mobility.
- Transcutaneous electrical nerve stimulation may be beneficial for improving gait speed after stroke when compared to No treatment.
- TENS with Task-related training may be beneficial for improving gait speed, gait endurance, and functional mobility, but not spasticity, after stroke when compared to TENS; the literature is mixed regarding muscle strength.
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving gait speed and functional mobility, but not muscle strength, spasticity, and gait endurance, after stroke when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training.
- Transcutaneous electrical nerve stimulation may not be beneficial for improving spasticity, gait speed, gait endurance, and functional mobility after stroke when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training; the literature is mixed regarding muscle strength.
- Transcutaneous electrical nerve stimulation may be beneficial for improving gait speed after stroke when compared to No active treatment.
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving gait speed, but not muscle strength and spasticity, after stroke when compared to transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training.
- Task-Specific Training with Bobath Concept Approach may be beneficial for improving gait speed, but not biomechanical balance measures, activities of daily living, gait endurance, and balance, after stroke when compared to Task-Specific Training.
- Task-Specific Training may be beneficial for improving balance after stroke when compared to Trunk Training.
- Task-oriented approach training + Conventional PT may be beneficial for improving spasticity and activities of daily living after stroke when compared to Task-oriented training only.
- Manual therapy with task oriented training and home exercise program may be beneficial for improving functional mobility and balance, but not gait speed, after stroke when compared to conventional rehab; the literature is mixed regarding range of motion and quality of life.
- Manual therapy with task oriented training and home exercise program may be beneficial for improving range of motion, functional mobility, balance, and quality of life, but not gait speed, after stroke when compared to task oriented training with home exercise program.
- Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care may not be beneficial for improving muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Usual Care.

- Dual transcranial direct current stimulation with Task-specific training may not be beneficial for improving motor recovery, gait speed, functional mobility, balance, and quality of life after stroke when compared to Sham transcranial direct current stimulation with Task specific training.
- Bihemispheric transcranial direct current stimulation with task oriented training may be beneficial for improving motor recovery, but not activities of daily living, after stroke when compared to Sham transcranial direct current stimulation with task oriented therapy.
- Visual scanning exercises with task specific activities may be beneficial for improving balance, but not activities of daily living, after stroke when compared to Placebo eye exercises with task specific activities(not sham).
- Constraint-induced movement therapy with task specific training may be beneficial for improving spasticity and aerobic measures, but not motor recovery, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to modified constraint-induced movement therapy with task specific training.
- Faradic electrical stimulation with Task-oriented exercise may be beneficial for improving spasticity, but not functional mobility, after stroke when compared to Russian electrical stimulation with Task-oriented exercises; the literature is mixed regarding range of motion.
- Faradic electrical stimulation with Task-oriented exercise may be beneficial for improving spasticity, but not functional mobility, after stroke when compared to Conventional care with task- oriented approach or 40 min conventional care 5d/wk, for 6wks; the literature is mixed regarding range of motion.
- Single dose of botulinum toxin-A (500U) with Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting) may not be beneficial for improving spasticity, activities of daily living, and gait endurance after stroke when compared to Single dose of botulinum toxin-A (500U) or Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting).
- Task-specific training with Mental practice (Motor Imagery) may be beneficial for improving muscle strength and gait speed after stroke when compared to Task-specific training.
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving muscle strength and balance after stroke when compared to No active treatment (health education).
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving balance, but not muscle strength, after stroke when compared to Sham transcutaneous electrical nerve stimulation with Task- related training.
- Transcranial direct current stimulation with Task-related training may be beneficial for improving gait speed after stroke when compared to Task-related training; the literature is mixed regarding biomechanical gait measures.
- Gait training with postural control visual feedback on monitor with task specific exercises may be beneficial for improving biomechanical gait measures after stroke when compared to Gait training with physiotherapy.
- Task-specific training with Mental practice E2 Task-specific training and Cognitive training may be beneficial for improving biomechanical balance measures, but not motor recovery, gait speed, and functional mobility, after stroke when compared to No training.
- Task oriented circuit gait training may be beneficial for improving gait endurance after stroke when compared to Educational session on stroke management.
- Strength training of lower extremities may be beneficial for improving gait endurance after stroke when compared to Educational session on stroke management.
- Lower extremity task- specific rehabilitation may be beneficial for improving gait speed after stroke when compared to Immobilization of paretic LE and UE using inflatable pressure splint.
- Upper extremity task- specific rehabilitation may not be beneficial for improving gait speed after stroke when compared to Immobilization of paretic LE and UE using inflatable pressure splint.
- Task-oriented training with Abdominal drawing-in maneuver may be beneficial for improving activities of daily living and balance after stroke when compared to Conventional physical therapy.
- Task-oriented training may be beneficial for improving balance, but not activities of daily living, after stroke when compared to Conventional physical therapy.
- TENS with Task-related training may be beneficial for improving gait speed after stroke when compared to No treatment.

A.6 Constraint-Induced Movement Therapy (CIMT) (Table 6)

Key Points

- Modified constraint-induced movement therapy Therapy or Conventional Rehabilitation may be beneficial for improving motor recovery, muscle strength, and balance, but not biomechanical gait measures, gait speed, gait endurance, and quality of life, after stroke when compared to Neurodevelopmental Therapy or Conventional Rehabilitation; the literature is mixed regarding functional mobility.
- Modified constraint-induced movement therapy Use Therapy may be beneficial for improving motor recovery and quality of life, but not gait speed, functional mobility, and balance, after stroke when compared to Forced Use Therapy.
- Constraint-induced movement therapy with task specific training may be beneficial for improving spasticity and aerobic measures, but not motor recovery, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to modified constraint-induced movement therapy with task specific training.
- Game-based constraint-induced movement therapy with Traditional physical therapy may be beneficial for improving biomechanical balance measures, but not gait speed, functional mobility, and balance, after stroke when compared to Traditional physical therapy.
- Game-based constraint-induced movement therapy with Traditional physical therapy may be beneficial for improving biomechanical gait measures and biomechanical balance measures, but not gait speed, functional mobility, and balance, after stroke when compared to General game-based training with Traditional physical therapy.
- Constraint-induced movement therapy With Immobilization may be beneficial for improving gait speed and functional mobility, but not balance, after stroke when compared to Without Immobilization.
- Healbot no pelvic mode may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to Conventional gait training with treadmill.
- Constraint induced movement training on treadmill with home exercises may not be beneficial for improving biomechanical gait measures, functional mobility, and balance after stroke when compared to Treadmill training.

A.7 Non-Technological Overground Walking and Gait Training (Table 7)

Key Points

- Overground Walking may be beneficial for improving functional mobility and balance, but not biomechanical gait measures, range of motion, gait speed, gait endurance, and quality of life, after stroke when compared to Treadmill Training.
- Treadmill-based with augmented reality may not be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Overground walking with physical obstacles.
- High Intensity Overground Walking may be beneficial for improving motor recovery and gait endurance, but not muscle strength, aerobic measures, and activities of daily living, after stroke when compared to Conventional Therapy; the literature is mixed regarding quality of life.
- Community-based gait training may be beneficial for improving gait speed, functional mobility, and quality of life, but not activities of daily living and gait endurance, after stroke when compared to conventional training; the literature is mixed regarding falls and fear of falling.
- Bent Knee (Prowling) Gait Training may be beneficial for improving functional mobility after stroke when compared to Conventional Therapy; the literature is mixed regarding range of motion.
- Backward or Sideway Walking Training may be beneficial for improving gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, but not motor recovery, biomechanical gait measures, biomechanical balance measures, and muscle strength, after stroke when compared to Standing Practice or Conventional Therapy; the literature is mixed regarding activities of daily living.

- Lateral Walking Training with Conventional physical therapy may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Backward Walking Training with Conventional physical therapy.
- 15cm Stair Height Training with Comprehensive rehabilitation may be beneficial for improving neurophysiological measures, but not functional mobility and balance, after stroke when compared to 10cm Stair Height Training with Comprehensive rehabilitation.
- Stair or Ramp Training may be beneficial for improving biomechanical balance measures and balance, but not biomechanical gait measures and functional mobility, after stroke when compared to Flat Surface Gait Training; the literature is mixed regarding muscle strength.
- Gait Training with Motor Imagery may be beneficial for improving gait speed and functional mobility after stroke when compared to Conventional Gait Training.
- Gait Training or Overground Walking with Feedback may be beneficial for improving biomechanical gait measures and functional mobility, but not gait speed and gait endurance, after stroke when compared to Without Feedback.
- Gait Training with Postural Assistance Support may be beneficial for improving gait speed and functional mobility, but not motor recovery, activities of daily living, and balance, after stroke when compared to Gait Training with Conventional Support.
- Gait training with Insoles may be beneficial for improving biomechanical balance measures and gait speed, but not biomechanical gait measures and gait endurance, after stroke when compared to Gait training with Conventional Shoes.
- Accurate Adaptability Walking may be beneficial for improving motor recovery, but not gait speed, functional mobility, balance, and falls and fear of falling, after stroke when compared to Steady State Walking.
- Implicit Motor Learning with Walking may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Explicit Motor Learning with Walking.
- Curved Gait Training may be beneficial for improving functional mobility, but not biomechanical gait measures, neurophysiological measures, and gait speed, after stroke when compared to Straight Gait Training.
- Outward curved gait training may not be beneficial for improving biomechanical gait measures, neurophysiological measures, gait speed, and functional mobility after stroke when compared to Inward curved gait training.
- Gait Training on Sand may be beneficial for improving gait speed, but not functional mobility and balance, after stroke when compared to Gait Training on Firm Surface.
- Step activity monitoring behavioural intervention may not be beneficial for improving aerobic measures, gait speed, and gait endurance after stroke when compared to High-intensity Walking intervention with Step activity monitoring behavioural intervention.
- High-intensity Walking intervention may not be beneficial for improving aerobic measures, gait speed, and gait endurance after stroke when compared to Step activity monitoring behavioural intervention.
- High-intensity Walking intervention may not be beneficial for improving aerobic measures, gait speed, and gait endurance after stroke when compared to High-intensity Walking intervention with Step activity monitoring behavioural intervention.
- Conventional gait training therapy + Conductive (Petho) methods education may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, activities of daily living, gait speed, gait endurance, and functional mobility after stroke when compared to Conventional gait training.
- Robot-assisted overground gait training may be beneficial for improving motor recovery, activities of daily living, functional mobility, and balance after stroke when compared to Conventional rehab.
- Overground gait training with Rhythmic auditory stimulation may not be beneficial for improving motor recovery, activities of daily living, gait endurance, and balance after stroke when compared to Overground gait training; the literature is mixed regarding biomechanical gait measures and gait speed.
- Inclined treadmill training with overground walking may be beneficial for improving biomechanical gait measures, but not muscle strength, spasticity, and gait speed, after stroke when compared to Regular

treadmill training with overground walking; the literature is mixed regarding range of motion and functional mobility.

- Backward walking observational training & Conventional therapy may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility, and falls and fear of falling after stroke when compared to Landscape observational training (sham) & Conventional therapy.
- Action observation of backward walking may be beneficial for improving functional mobility after stroke when compared to Landscape video with Backward walking training.
- Gait training program (treadmill + overground walking) wearing a hip-assist robot may be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, gait speed, and falls and fear of falling, but not balance, after stroke when compared to Gait training (treadmill training + over ground walking).
- Error Augmentation treadmill training with Overground walking may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Conventional treadmill training with Overground walking.
- Overground walking with body weight supported may not be beneficial for improving motor recovery, biomechanical gait measures, activities of daily living, gait speed, and gait endurance after stroke when compared to Treadmill training with body weight supported.
- Overground walking training with i-Walker robotic assistive device may be beneficial for improving gait speed, gait endurance, and functional mobility, but not motor recovery, spasticity, and activities of daily living, after stroke when compared to Conventional overground walking training.
- Overground gait training may not be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to Treadmill gait training.
- Long-term Treadmill and Overground Walking may be beneficial for improving gait speed, gait endurance, and quality of life, but not activities of daily living, functional mobility, and falls and fear of falling, after stroke when compared to No Intervention; the literature is mixed regarding biomechanical gait measures.
- Long-term Treadmill and Overground Walking may be beneficial for improving gait endurance, but not biomechanical gait measures, activities of daily living, gait speed, and falls and fear of falling, after stroke when compared to Short-term Treadmill and Overground Walking; the literature is mixed regarding functional mobility and quality of life.
- Home-based cycle ergometer exercise may not be beneficial for improving gait speed, gait endurance, balance, and quality of life after stroke when compared to Home-based overground walking exercise.
- Treadmill training with Rehabilitation program may be beneficial for improving gait speed and gait endurance after stroke when compared to Overground gait training with Rehabilitation program; the literature is mixed regarding biomechanical gait measures.
- Intensive locomotor training (body weight supported treadmill with overground walking) may be beneficial for improving gait speed, but not aerobic measures, functional mobility, and balance, after stroke when compared to No training.
- Functional electrical stimulation of Dorsiflexors and Plantar Flexors with Overground Walking program may be beneficial for improving gait endurance and quality of life, but not muscle strength, spasticity, and functional mobility, after stroke when compared to Overground Walking program.
- Gait Trainer GT I (Rehastim) may not be beneficial for improving motor recovery, gait speed, gait endurance, and functional mobility after stroke when compared to Conventional physiotherapy.
- Gait Trainer GT I (Rehastim) may not be beneficial for improving motor recovery, gait speed, gait endurance, and functional mobility after stroke when compared to Overground gait training.
- Treadmill training with overground gait training may be beneficial for improving gait speed and gait endurance, but not quality of life, after stroke when compared to Placebo program of low- intensity home exercise program with Telerehabilitation; the literature is mixed regarding biomechanical gait measures.
- Overground gait training using E-Go device with Standard Physiotherapy may not be beneficial for improving motor recovery, activities of daily living, gait endurance, functional mobility, and balance after stroke when compared to Overground walking training with Standard Physiotherapy.

A.8 Cycle Ergometer Training (Table 8)

Key Points

- Cycle Ergometer Training may be beneficial for improving motor recovery, muscle strength, range of motion, gait speed, gait endurance, functional mobility, and balance, but not spasticity, aerobic measures, and activities of daily living, after stroke when compared to Conventional Therapy.
- Cycle Ergometer Training may be beneficial for improving functional mobility and balance, but not motor recovery, muscle strength, and quality of life, after stroke when compared to Sham or No Treatment; the literature is mixed regarding aerobic measures, gait speed, and gait endurance.
- Cycle Ergometer may be beneficial for improving aerobic measures and functional mobility, but not motor recovery and balance, after stroke when compared to Stretching.
- In-Bed Cycling may not be beneficial for improving activities of daily living and gait endurance after stroke when compared to Usual Care.
- Active Cycling with Education and Coaching may not be beneficial for improving muscle strength, aerobic measures, gait speed, and functional mobility after stroke when compared to Active Cycling with Education or Passive Mobilization.
- Cycle Ergometer and Treadmill Training may not be beneficial for improving aerobic measures, gait endurance, functional mobility, and balance after stroke when compared to Conventional Therapy.
- Cycle Ergometer Training may be beneficial for improving gait speed, but not biomechanical gait measures, after stroke when compared to Overground Walking; Cycle Ergometer Training may result in lesser improvements in range of motion when compared to Overground Walking.
- Aerobic training (Ergometer bicycle training) may be beneficial for improving biomechanical balance measures, but not gait speed, after stroke when compared to Aerobic training (sliding machine).
- Sham progressive resistance training with Cycling may be beneficial for improving gait endurance after stroke when compared to Sham progressive resistance training with Sham cycling.
- Progressive Resistance Training and Cycling may be beneficial for improving muscle strength and gait endurance, but not quality of life, after stroke when compared to Sham Progressive Resistance Training and Cycling; the literature is mixed regarding aerobic measures, gait speed, and functional mobility.
- Interlimb Coupling Training may be beneficial for improving motor recovery and functional mobility, but not activities of daily living, after stroke when compared to Conventional Therapy.
- Cycle Ergometry with virtual reality may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and balance after stroke when compared to Cycle Ergometry.
- Electromyography-triggered Pedalling Training may be beneficial for improving motor recovery, biomechanical gait measures, and gait speed after stroke when compared to Pedalling Training; the literature is mixed regarding neurophysiological measures.
- Aerobic cycling exercise training may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Computerized cognitive training or Aerobic exercise with computerized cognitive training.
- Therapist-supervised in home Cycle ergometer with 30min pedaling may not be beneficial for improving neurophysiological measures after stroke when compared to No treatment.
- Repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and balance after stroke when compared to Sham repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise.
- Circuit walking, balance, cycling and strength training (CBCS) may be beneficial for improving motor recovery, gait endurance, balance, and quality of life, but not gait speed, after stroke when compared to Sociocultural intervention (board games, cultural discourse and drama).
- Brain-computer interface- controlled pedaling training may be beneficial for improving motor recovery after stroke when compared to Sham brain-computer interface-controlled pedaling training.
- ExoAtlet exoskeleton exercises with rehabilitation may be beneficial for improving muscle strength, activities of daily living, gait speed, and functional mobility, but not spasticity, after stroke when compared to Ortorent MOTO pedal trainer for active-passive training with rehabilitation; the literature is mixed regarding balance.

- Leg cycling with functional electrical stimulation with interval patterns timing may be beneficial for improving spasticity and range of motion, but not gait speed and balance, after stroke when compared to Leg cycling with functional electrical stimulation with linear patterns timing; the literature is mixed regarding functional mobility.
- High-frequency repetitive transcranial magnetic stimulation with Hesed coil during active cycling may be beneficial for improving motor recovery, spasticity, and neurophysiological measures, but not gait speed and gait endurance, after stroke when compared to Sham repetitive transcranial magnetic stimulation during cycling.
- Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not be beneficial for improving gait speed, gait endurance, functional mobility, and quality of life after stroke when compared to Sham Combined aerobic and resistance training with Sham Cognitive training.
- Protein supplement with Cycle ergometer exercise may be beneficial for improving motor recovery, neurophysiological measures, aerobic measures, gait endurance, functional mobility, and balance after stroke when compared to Carbohydrate supplement with Cycle ergometer exercise.
- Aerobic training on cycle ergometer may not be beneficial for improving muscle strength, aerobic measures, gait speed, gait endurance, and balance after stroke when compared to Sham training of upper extremities.
- Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer) may be beneficial for improving motor recovery, but not gait speed, gait endurance, and functional mobility, after stroke when compared to Conventional Care.
- Cycling with functional electrical stimulation and conventional care may not be beneficial for improving muscle strength, spasticity, and activities of daily living after stroke when compared to Conventional care.
- Active cycling with functional electrical stimulation may be beneficial for improving aerobic measures, but not biomechanical gait measures, activities of daily living, gait speed, and gait endurance, after stroke when compared to Physiotherapy.
- Active Leg Cycling with functional electrical stimulation (unilaterally on the paretic lower limb) may be beneficial for improving functional mobility, but not muscle strength and spasticity, after stroke when compared to Active Leg Cycling; Active Leg Cycling with functional electrical stimulation (unilaterally on the paretic lower limb) may result in lesser improvements in gait speed when compared to Active Leg Cycling.
- Conventional Rehabilitation with Cycling training and biofeedback may be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Conventional Rehabilitation (CR).
- Home-based cycle ergometer exercise may not be beneficial for improving gait speed, gait endurance, balance, and quality of life after stroke when compared to Home-based overground walking exercise.
- Functional electrical stimulation with cycling may not be beneficial for improving biomechanical balance measures, spasticity, and gait speed after stroke when compared to Cycling.
- Cycling induced by functional electrical stimulation with Conventional Rehabilitation may be beneficial for improving muscle strength, but not gait speed, after stroke when compared to Cycling placebo functional electrical stimulation with Conventional Rehabilitation.
- Cycling with functional electrical stimulation may be beneficial for improving motor recovery and gait speed, but not aerobic measures, gait endurance, and functional mobility, after stroke when compared to Cycling with Sham functional electrical stimulation; the literature is mixed regarding muscle strength and balance.
- Aerobic cycling with progressive resistance training (PRT) may not be beneficial for improving aerobic measures, gait speed, gait endurance, and quality of life after stroke when compared to Sham cycling with Sham PRT.
- Functional electrical stimulation with Cycling Ergometer and Conventional Care may not be beneficial for improving motor recovery, gait speed, and balance after stroke when compared to Conventional Care; the literature is mixed regarding muscle strength.
- Body weight supported treadmill with upper extremity ergometry training may be beneficial for improving gait speed, but not muscle strength and gait endurance, after stroke when compared to Resistive leg cycling with upper extremity ergometry training.

- Body weight supported treadmill with upper extremity ergometry training may not be beneficial for improving muscle strength, gait speed, and gait endurance after stroke when compared to body weight supported treadmill with resistive leg cycling training or body weight supported treadmill with lower extremity progressive resistive exercise.

A.9 Treadmill Training (Table 9)

Key Points

- Treadmill Training may be beneficial for improving aerobic measures and gait endurance, but not biomechanical gait measures, activities of daily living, gait speed, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy.
- Treadmill Training may not be beneficial for improving biomechanical gait measures, range of motion, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Overground Training.
- Treadmill training with Rehabilitation program may be beneficial for improving gait speed and gait endurance after stroke when compared to Overground gait training with Rehabilitation program; the literature is mixed regarding biomechanical gait measures.
- Body weight supported Treadmill Training may be beneficial for improving motor recovery, gait speed, and falls and fear of falling, but not biomechanical gait measures, muscle strength, aerobic measures, activities of daily living, functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy; the literature is mixed regarding neurophysiological measures and gait endurance.
- Body weight supported treadmill training may not be beneficial for improving gait speed after stroke when compared to body weight supported treadmill training with Conventional care; Body weight supported treadmill training may result in lesser improvements in functional mobility, balance, and falls and fear of falling when compared to body weight supported treadmill training with Conventional care.
- Body weight supported Treadmill Training may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, aerobic measures, sensory and proprioceptive function, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Overground Walking.
- Body weight supported Treadmill Training may be beneficial for improving biomechanical gait measures, neurophysiological measures, and functional mobility, but not motor recovery and gait endurance, after stroke when compared to Treadmill Training; the literature is mixed regarding gait speed and balance.
- Body weight supported Treadmill Training with Mobility Skills may not be beneficial for improving gait speed, gait endurance, balance, and falls and fear of falling after stroke when compared to body weight supported Treadmill Training.
- Body weight supported treadmill with upper extremity ergometry training may be beneficial for improving gait speed, but not muscle strength and gait endurance, after stroke when compared to Resistive leg cycling with upper extremity ergometry training.
- Body weight supported treadmill with upper extremity ergometry training may not be beneficial for improving muscle strength, gait speed, and gait endurance after stroke when compared to body weight supported treadmill with resistive leg cycling training or body weight supported treadmill with lower extremity progressive resistive exercise.
- Body weight supported Treadmill Training with Facilitation Technique may not be beneficial for improving motor recovery, biomechanical gait measures, activities of daily living, and gait speed after stroke when compared to body weight supported Training with Mechanical Assistance.
- Body weight supported Treadmill Training for Different Durations may not be beneficial for improving motor recovery, gait speed, gait endurance, balance, falls and fear of falling, and quality of life after stroke when compared to Home Exercise.
- Treadmill Training with Nordic Poles may be beneficial for improving activities of daily living, gait endurance, functional mobility, and balance, but not gait speed, after stroke when compared to Treadmill Training.
- Treadmill Training with Load may not be beneficial for improving motor recovery, biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, activities of daily living, gait

speed, and falls and fear of falling after stroke when compared to Treadmill Training without Load or Conventional Therapy; the literature is mixed regarding functional mobility.

- Treadmill Training with Incline may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, spasticity, activities of daily living, functional mobility, and balance after stroke when compared to Treadmill Training with Decline or Level Treadmill Training; Treadmill Training with Incline may result in lesser improvements in gait endurance when compared to Treadmill Training with Decline or Level Treadmill Training; the literature is mixed regarding range of motion and gait speed.
- Treadmill Training with Increased Speed may be beneficial for improving biomechanical gait measures, gait speed, and gait endurance, but not balance, after stroke when compared to Treadmill Training with Increased Incline.
- Constraint Induced Movement with Home Exercise may not be beneficial for improving biomechanical gait measures, functional mobility, and balance after stroke when compared to Treadmill Training.
- Treadmill Training with Foot Drop Stimulator may be beneficial for improving biomechanical gait measures, spasticity, range of motion, neurophysiological measures, and functional mobility after stroke when compared to Foot Drop Stimulator.
- Perturbation Treadmill Training may be beneficial for improving balance, but not muscle strength, activities of daily living, gait speed, and falls and fear of falling, after stroke when compared to Treadmill Training.
- Turning Treadmill Training may be beneficial for improving muscle strength, gait speed, and balance, but not biomechanical gait measures and biomechanical balance measures, after stroke when compared to Treadmill Training.
- Treadmill Training with Mirror Therapy may not be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Treadmill Training.
- Treadmill Training with Proprioceptive Neuromuscular Facilitation may be beneficial for improving gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill Training.
- Body weight supported Treadmill Training may not be beneficial for improving biomechanical gait measures, range of motion, activities of daily living, and gait speed after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Treadmill Training with Obstacles may be beneficial for improving gait endurance and balance, but not gait speed, functional mobility, and falls and fear of falling, after stroke when compared to Treadmill Training.
- Treadmill Training on Unstable Surface may be beneficial for improving gait endurance and functional mobility, but not gait speed, after stroke when compared to Treadmill Training.
- Treadmill Training with Handrails may be beneficial for improving biomechanical gait measures after stroke when compared to Treadmill Training.
- Treadmill Training with Horizontal Force may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Treadmill Training; the literature is mixed regarding balance.
- Treadmill-based C-Mill (using gait-dependent augmented reality) may not be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Overground walking therapy (walking-adaptability exercises with physical obstacles).
- Treadmill Training with virtual reality may be beneficial for improving biomechanical gait measures, gait speed, functional mobility, and balance, but not biomechanical balance measures, after stroke when compared to Other Training.
- Treadmill Training with Smartphone Application may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Treadmill Training.
- Treadmill Training with Visual Deprivation may be beneficial for improving gait speed, but not gait endurance and functional mobility, after stroke when compared to Treadmill Training; the literature is mixed regarding biomechanical gait measures.
- Backward Treadmill Training may be beneficial for improving biomechanical balance measures and functional mobility, but not motor recovery, biomechanical gait measures, spasticity, gait speed, balance, and falls and fear of falling, after stroke when compared to Treadmill or Conventional Rehabilitation; the literature is mixed regarding aerobic measures and gait endurance.

- Body weight supported, backward and forward treadmill training may not be beneficial for improving biomechanical gait measures after stroke when compared to body weight supported, forward treadmill training or body weight supported, backward treadmill training.
- Backward treadmill with partial body weight supported may be beneficial for improving functional mobility, but not biomechanical gait measures, gait speed, and balance, after stroke when compared to Forward treadmill with partial body weight supported treadmill.
- Treadmill Training with Overground Training may be beneficial for improving gait speed and gait endurance, but not biomechanical gait measures, aerobic measures, activities of daily living, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Home Exercise/ no treatment.
- Long-term Treadmill and Overground Walking may be beneficial for improving gait endurance, functional mobility, and quality of life, but not biomechanical gait measures, activities of daily living, and gait speed, after stroke when compared to Short-term Treadmill and Overground Walking.
- High Intensity Treadmill Training may be beneficial for improving biomechanical gait measures, but not aerobic measures, gait speed, gait endurance, functional mobility, and quality of life, after stroke when compared to Low Intensity Treadmill Training.
- Fast Speed Treadmill Training with functional electrical stimulation may be beneficial for improving gait speed, but not gait endurance, after stroke when compared to Self-selected or Fast Speed Treadmill Training.
- Speed Dependent Treadmill Training may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility, but not balance, after stroke when compared to Other Treadmill Training.
- Body weight supported treadmill training (fast speed) may result in lesser improvements in gait speed when compared to body weight supported treadmill training (slow speed) or body weight supported treadmill training (variable speed).
- Speed-dependent Treadmill Training may not be beneficial for improving functional mobility and balance after stroke when compared to Task-oriented Training.
- Error Augmentation Treadmill Training may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Treadmill Training.
- Treadmill Training may be beneficial for improving aerobic measures and balance, but not neurophysiological measures, gait speed, and functional mobility, after stroke when compared to Stretching; the literature is mixed regarding gait endurance.
- Treadmill Training with Orthotic Devices may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Treadmill Training; the literature is mixed regarding balance.
- Electromechanical gait trainer therapy with Conventional rehabilitation may be beneficial for improving functional mobility, but not motor recovery, spasticity, and gait speed, after stroke when compared to Body weight-supported treadmill training with Conventional rehabilitation.
- Treadmill Training with Action Observation may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill Training.
- Circular treadmill training with ambulation training may be beneficial for improving biomechanical gait measures, neurophysiological measures, and gait speed after stroke when compared to Regular treadmill training+ ambulation training.
- Overground gait training + visual cue feedback may not be beneficial for improving motor recovery, biomechanical gait measures, gait speed, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Standard physiotherapy.
- Treadmill walking training + conventional PT may not be beneficial for improving gait speed and gait endurance after stroke when compared to conventional PT.
- Augmented reality treadmill-based gait adaptation training may be beneficial for improving functional mobility and balance after stroke when compared to Treadmill training with overground walking; the literature is mixed regarding gait speed.
- Rhythmic Auditory Stimulation with Custom Physiotherapy program and Treadmill gait training may be beneficial for improving gait speed and functional mobility after stroke when compared to Custom

physiotherapy program with Treadmill gait training; the literature is mixed regarding biomechanical gait measures.

- Treadmill training with HEALBOT exoskeleton may be beneficial for improving neurophysiological measures and functional mobility, but not balance, after stroke when compared to Treadmill training; the literature is mixed regarding biomechanical gait measures and gait speed.
- Functional electrical stimulation with treadmill training may be beneficial for improving gait endurance and functional mobility, but not gait speed, after stroke when compared to Treadmill training.
- Anodal transcranial direct current stimulation with Treadmill training may not be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to Sham transcranial direct current stimulation with Treadmill training.
- Bilateral transcranial direct current stimulation and Treadmill may not be beneficial for improving motor recovery, biomechanical gait measures, neurophysiological measures, gait speed, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with Treadmill.
- Bilateral transcranial direct current stimulation and Treadmill may be beneficial for improving motor recovery, biomechanical gait measures, neurophysiological measures, and gait speed, but not functional mobility, after stroke when compared to Cathodal transcranial direct current stimulation and Treadmill.
- Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, balance, and falls and fear of falling after stroke when compared to Sham taping with exercise training.
- Underwater Treadmill gait training with conventional rehabilitation may not be beneficial for improving biomechanical gait measures after stroke when compared to Overground gait training with conventional rehabilitation; the literature is mixed regarding gait speed.
- Functional electrical stimulation with treadmill gait training may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Sham Functional electrical stimulation with treadmill gait training.
- Bicephalic Transcranial direct-current stimulation with Footdrop stimulator and Treadmill gait training may not be beneficial for improving spasticity, gait endurance, functional mobility, and quality of life after stroke when compared to Sham transcranial direct-current stimulation with Footdrop stimulator and treadmill gait training.
- Body weight supported treadmill training (BWST) with conventional rehabilitation may be beneficial for improving biomechanical gait measures, gait speed, functional mobility, and balance after stroke when compared to Overground gait training with conventional rehabilitation.
- Dual-task gait training with treadmill may be beneficial for improving gait speed, but not biomechanical gait measures, functional mobility, and falls and fear of falling, after stroke when compared to Single-task gait training with treadmill.
- Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not be beneficial for improving gait speed, gait endurance, functional mobility, and quality of life after stroke when compared to Sham Combined aerobic and resistance training with Sham Cognitive training.
- Treadmill training using insole on less affected side may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill training.
- Gait training with Gait Exercise Assist Robot (GEAR) may be beneficial for improving functional mobility, but not biomechanical gait measures, gait speed, and quality of life, after stroke when compared to Gait training with treadmill; the literature is mixed regarding gait endurance.
- High frequency repetitive transcranial magnetic stimulation with Treadmill Training may be beneficial for improving gait speed, gait endurance, and functional mobility after stroke when compared to Sham repetitive transcranial magnetic stimulation with Treadmill Training.
- Cerebellar transcranial direct current stimulation with split-belt treadmill training may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Sham cerebellar transcranial direct current stimulation with split-belt treadmill training.
- Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to AMT priming only (Ankle motor tracking with

Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training).

- Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may be beneficial for improving quality of life, but not motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, after stroke when compared to 15min rest with High- intensity speed-based treadmill training.
- Backward treadmill training with botulinum toxin type A therapy may be beneficial for improving biomechanical balance measures and gait speed, but not biomechanical gait measures and spasticity, after stroke when compared to forward treadmill training with botulinum toxin type A therapy.
- High-Intensity Interval Training – Treadmill may be beneficial for improving neurophysiological measures after stroke when compared to Moderate-intensity Continuous Exercise - Treadmill; the literature is mixed regarding gait speed.
- Dual-task (virtual reality-based UL training while walking on treadmill) may be beneficial for improving gait speed, balance, and falls and fear of falling, but not functional mobility, after stroke when compared to Single task treadmill walking.
- Treadmill Training with Mirror Therapy may not be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Treadmill Training with Sham.
- Gait training program (treadmill + overground walking) wearing a hip-assist robot may be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, gait speed, and falls and fear of falling, but not balance, after stroke when compared to Gait training (treadmill training + over ground walking).
- Hybrid Assistive Limb (HAL) exoskeleton with Bodyweight supported treadmill training may not be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Conventional Physical therapy.
- High Frequency repetitive transcranial magnetic stimulation (5Hz) with Treadmill Training may be beneficial for improving motor recovery and gait speed, but not neurophysiological measures, after stroke when compared to Sham repetitive transcranial magnetic stimulation with Treadmill Training.
- Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may be beneficial for improving gait endurance and functional mobility after stroke when compared to Sham taping with treadmill training.
- Body weight support treadmill training with visual biofeedback may be beneficial for improving gait endurance, but not biomechanical gait measures and functional mobility, after stroke when compared to Body weight support treadmill training; the literature is mixed regarding gait speed.
- Water-based aerobic exercise on a motorized aquatic treadmill with Conventional rehabilitation therapy may not be beneficial for improving motor recovery, aerobic measures, activities of daily living, balance, and quality of life after stroke when compared to Aerobic Exercise (by upper and lower body ergometers) with Conventional rehabilitation therapy; the literature is mixed regarding muscle strength.
- Aquatic-based treadmill aerobic training with conventional care may be beneficial for improving aerobic measures, but not activities of daily living and gait endurance, after stroke when compared to Land-based aerobic exercises on cycle ergometer with conventional care.
- Rhythmic auditory stimulation with treadmill training and conventional physical therapy may be beneficial for improving gait endurance, but not biomechanical gait measures and biomechanical balance measures, after stroke when compared to Treadmill training with conventional physical therapy; the literature is mixed regarding gait speed.
- Rhythmic auditory stimulation with treadmill training and conventional physical therapy may not be beneficial for improving biomechanical balance measures and gait endurance after stroke when compared to Neurodevelopmental treatment with conventional physical therapy; the literature is mixed regarding biomechanical gait measures and gait speed.
- Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may be beneficial for improving motor recovery and muscle strength, but not activities of daily living, gait speed, functional mobility, and balance, after stroke when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.

- Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may be beneficial for improving motor recovery, gait speed, and muscle strength, but not activities of daily living, after stroke when compared to Conventional physical therapy with treadmill training.
- Body weight supported treadmill training with anodal transcranial direct current stimulation may be beneficial for improving gait speed, but not motor recovery and balance, after stroke when compared to Body weight supported treadmill training with sham transcranial direct current stimulation; the literature is mixed regarding functional mobility.
- Whole body vibration with Treadmill training may be beneficial for improving biomechanical gait measures and gait speed, but not gait endurance, after stroke when compared to Exercises on platform without vibration with Treadmill training.
- High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc) may be beneficial for improving gait speed and quality of life, but not functional mobility, balance, and falls and fear of falling, after stroke when compared to Conventional physical therapy care; the literature is mixed regarding biomechanical gait measures and gait endurance.
- Treadmill training with visual biofeedback and physiotherapy exercises may not be beneficial for improving biomechanical gait measures and range of motion after stroke when compared to Treadmill training with physiotherapy exercises.
- Treadmill training with Gait Trainer 2 Biodex biofeedback (30-45min/d) with Conventional individual exercises may not be beneficial for improving biomechanical balance measures, functional mobility, and balance after stroke when compared to Treadmill training without biofeedback with Conventional individual exercises.
- Aquatic therapy (physical therapy exercises) with aquatic treadmill may be beneficial for improving activities of daily living and functional mobility, but not spasticity and neurophysiological measures, after stroke when compared to Conventional physical therapy exercise with land-based treadmill; the literature is mixed regarding muscle strength and range of motion.
- Treadmill training with Rhythmic auditory stimulation may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Treadmill training.
- Treadmill training with Rhythmic auditory feedback may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Treadmill training.
- Inclined treadmill training with Rhythmic auditory stimulation may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Treadmill training.
- Virtual reality treadmill training-based community ambulation may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and falls and fear of falling after stroke when compared to Community ambulation training.
- Virtual reality treadmill training-based community ambulation may be beneficial for improving functional mobility and falls and fear of falling, but not biomechanical gait measures, gait speed, and gait endurance, after stroke when compared to Conventional rehabilitation.
- Treadmill training with Virtual reality and Ankle robotics may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, range of motion, and gait speed after stroke when compared to Seated training with Virtual reality and Ankle robotics.
- Task-oriented treadmill training with conventional therapy may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill training with conventional therapy.
- Partial body-weight support treadmill training with Visual biofeedback may not be beneficial for improving biomechanical gait measures and range of motion after stroke when compared to Partial body-weight support treadmill training.
- Treadmill training with visual biofeedback and basic physiotherapy may not be beneficial for improving biomechanical gait measures, activities of daily living, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill training with basic physiotherapy.
- Cognitive-motor dual task training while treadmill walking with Conventional rehabilitation may be beneficial for improving gait speed, but not functional mobility, after stroke when compared to Single task training on Treadmill walking with Conventional rehabilitation.

- Treadmill training with Rhythmic auditory stimulation may be beneficial for improving gait speed, gait endurance, and functional mobility after stroke when compared to Overground training with Rhythmic auditory stimulation; the literature is mixed regarding biomechanical gait measures.
- Treadmill training with Virtual reality may be beneficial for improving biomechanical balance measures after stroke when compared to Conventional rehabilitation.
- Treadmill training with functional electrical stimulation on gluteus medius and tibialis anterior may be beneficial for improving gait speed, but not gait endurance and balance, after stroke when compared to Treadmill training; the literature is mixed regarding biomechanical gait measures and muscle strength.
- Treadmill training with Tilt sensor functional electrical stimulation with conventional physical therapy may be beneficial for improving gait speed, functional mobility, and balance, but not muscle strength, after stroke when compared to Treadmill training with Placebo Tilt sensor functional electrical stimulation with conventional physical therapy.
- Overground gait training with ankle mass may not be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to Overground gait training without mass or Treadmill gait training without mass.
- Body Weight-Supported Treadmill Training with functional electrical stimulation may be beneficial for improving biomechanical gait measures, gait speed, functional mobility, and balance after stroke when compared to Body Weight Supported Treadmill Training.
- Underwater treadmill walking may be beneficial for improving biomechanical gait measures and neurophysiological measures, but not functional mobility, after stroke when compared to Overground treadmill walking.
- Treadmill training with Virtual reality may be beneficial for improving gait speed after stroke when compared to Treadmill training; the literature is mixed regarding functional mobility and falls and fear of falling.
- Treadmill with optic flow with conventional physical therapy may be beneficial for improving gait speed, gait endurance, and functional mobility, but not balance, after stroke when compared to Treadmill with conventional physical therapy.
- Treadmill with optic flow with conventional physical therapy may be beneficial for improving balance after stroke when compared to Conventional therapy; the literature is mixed regarding gait speed, gait endurance, and functional mobility.
- Aerobic training (treadmill and cycle ergometer) may not be beneficial for improving aerobic measures, gait endurance, functional mobility, and balance after stroke when compared to Conventional rehabilitation.
- Treadmill training with Virtual reality and Conventional rehabilitation may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, and functional mobility after stroke when compared to Treadmill training with Conventional rehabilitation.
- Aerobic training (cycle ergometer, treadmill, balance) may be beneficial for improving aerobic measures and activities of daily living after stroke when compared to Conventional rehabilitation.
- Specialized task oriented locomotor training (includes using Tilt table, limb-load monitor, isokinetic device and treadmill training) with Conventional physiotherapy may not be beneficial for improving motor recovery, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Conventional physiotherapy.
- Treadmill training with Virtual reality may not be beneficial for improving motor recovery, biomechanical gait measures, gait endurance, and functional mobility after stroke when compared to Stepping over real objects on 10m walkway.
- Treadmill training and overground gait training may be beneficial for improving gait speed and gait endurance, but not quality of life, after stroke when compared to Placebo program of low- intensity home exercise program with Telerehabilitation; the literature is mixed regarding biomechanical gait measures.
- Baseline conventional therapy with Treadmill training with partial body weight supported and Individual physical therapy may be beneficial for improving functional mobility, but not motor recovery and gait speed, after stroke when compared to Baseline conventional therapy with Treadmill training with partial body weight supported.
- Early, intensive, gait- oriented Task specific training (isokinetic device, treadmill, tilt table) with conventional hospital care may not be beneficial for improving activities of daily living, gait speed, and

balance after stroke when compared to Early, intensive traditional physical therapy approach with conventional hospital care or Conventional physical therapy and conventional hospital care or 60min/d, 5d/wk, 5wks.

- BWS treadmill training with Conventional care may be beneficial for improving gait speed, functional mobility, balance, and falls and fear of falling after stroke when compared to Conventional training.
- Forward treadmill with partial BWS treadmill may be beneficial for improving functional mobility, but not biomechanical gait measures, gait speed, and balance, after stroke when compared to Conventional rehabilitation.
- Auditory stimulation with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to 15min rest with High- intensity speed-based treadmill training.
- AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training).
- Inclined treadmill training may be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Treadmill training; the literature is mixed regarding biomechanical gait measures.
- Inclined treadmill training with Rhythmic auditory stimulation may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Inclined treadmill training.
- Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to 15min rest with High- intensity speed-based treadmill training.
- Treadmill training with BWS via overhead harness may not be beneficial for improving functional mobility after stroke when compared to Overground gait training.
- Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.

A.10 Physiotherapy and Exercise Programs (Table 10)

Key Points

- Body Weight Shift Technique may be beneficial for improving biomechanical balance measures, gait speed, and balance, but not motor recovery, after stroke when compared to Conventional Therapy.
- Neurorestoration Protocol Physiotherapy may be beneficial for improving activities of daily living and balance, but not neurophysiological measures, after stroke when compared to Conventional Physiotherapy.
- Leisure-time Physical Activity may not be beneficial for improving activities of daily living, gait endurance, and functional mobility after stroke when compared to Nonleisure-time Physical Activity.
- Self-regulation Rehabilitation may not be beneficial for improving motor recovery after stroke when compared to Conventional Therapy; the literature is mixed regarding activities of daily living.
- Range of Motion exercise program by themselves may not be beneficial for improving range of motion, pain, and activities of daily living after stroke when compared to Range of Motion exercise program with physical help.

- Agility Exercise may be beneficial for improving biomechanical gait measures, but not neurophysiological measures, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Stretching.
- Physio equipment may be beneficial for improving balance, but not aerobic measures, after stroke when compared to Conventional Therapy.
- Early Rehabilitation Programs may be beneficial for improving motor recovery, but not functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke; the literature is mixed regarding activities of daily living.
- Early Conventional therapy (after 24-48 hours) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Late Conventional therapy (72-96 hours post stroke).
- Physical Therapy may be beneficial for improving spasticity, activities of daily living, and balance, but not motor recovery, gait speed, and functional mobility, after stroke when compared to No Treatment.
- Occupational Therapy may be beneficial for improving activities of daily living, but not quality of life, after stroke when compared to No Treatment.
- Custom Exercise Programs may be beneficial for improving sensory and proprioceptive function, but not motor recovery, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy.
- Aerobic and Resistance Training may not be beneficial for improving range of motion, neurophysiological measures, aerobic measures, gait endurance, and functional mobility after stroke when compared to Aerobic Training.
- Aerobic and Resistance Training may be beneficial for improving gait speed and gait endurance, but not aerobic measures, functional mobility, and balance, after stroke when compared to Conventional Care.
- Closed Chain Exercise may be beneficial for improving neurophysiological measures, but not motor recovery, biomechanical gait measures, range of motion, functional mobility, and balance, after stroke when compared to Open Chain Exercise or Rehabilitation; the literature is mixed regarding gait speed.
- Sling Exercise Therapy may be beneficial for improving biomechanical gait measures, pain, gait speed, functional mobility, and balance after stroke when compared to Conventional Therapy; the literature is mixed regarding motor recovery and activities of daily living.
- Muscle energy technique with conventional therapy may result in lesser improvements in motor recovery, pain, activities of daily living, functional mobility, balance, and quality of life when compared to Neurac with conventional therapy or Muscle energy technique, Neurac and conventional therapy.
- Aerobic Exercise with Cognitive Training may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Nonaerobic Exercise with Unstructured Mental Activities or Sham; the literature is mixed regarding gait endurance.
- Virtual Reality Exercise Program may not be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to Customized Physiotherapy or Conventional Physiotherapy.
- High-intensity Functional Exercise Program may be beneficial for improving falls and fear of falling, but not activities of daily living and balance, after stroke when compared to Education.
- Repetitive weight bearing exercises repeated 40 times may be beneficial for improving biomechanical gait measures after stroke when compared to Repetitive weight bearing exercises repeated 20 times.
- Higher Intensity Training may be beneficial for improving motor recovery and neurophysiological measures, but not muscle strength, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Lower Intensity Training or Conventional Care; the literature is mixed regarding biomechanical gait measures.
- Low-to-Moderate Intensity Continuous Training may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Moderate Intensity Interval Training.
- Low-to-Moderate Intensity Continuous Training may not be beneficial for improving motor recovery after stroke when compared to Reduced-Exertion High-Intensity Interval Training; Low-to-Moderate Intensity Continuous Training may result in lesser improvements in activities of daily living when compared to Reduced-Exertion High-Intensity Interval Training.

- Increased Duration of Exercise may not be beneficial for improving motor recovery, muscle strength, spasticity, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Conventional Care/Exercise.
- Community-based Physical Activity may be beneficial for improving range of motion, aerobic measures, and gait speed, but not activities of daily living, gait endurance, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to No Intervention; the literature is mixed regarding muscle strength.
- Community-based Exercise Program may be beneficial for improving motor recovery, but not muscle strength, spasticity, aerobic measures, activities of daily living, gait speed, functional mobility, balance, and quality of life, after stroke when compared to Other Care; the literature is mixed regarding gait endurance.
- Community-based Exercise Program may be beneficial for improving activities of daily living and gait endurance, but not muscle strength, functional mobility, balance, and falls and fear of falling, after stroke when compared to Upper Extremity Exercise Program; the literature is mixed regarding aerobic measures and gait speed.
- Non-Paretic Side Training may be beneficial for improving activities of daily living after stroke when compared to Conventional Therapy; the literature is mixed regarding balance.
- Falls Prevention Program may not be beneficial for improving activities of daily living, functional mobility, and falls and fear of falling after stroke when compared to Usual Care.
- Skating Exercise may be beneficial for improving functional mobility, balance, and quality of life, but not aerobic measures, after stroke when compared to Treadmill Training.
- High-Intensity Training with Acute Intermittent Hypoxia may be beneficial for improving gait speed, but not aerobic measures, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to High-Intensity Training Alone; the literature is mixed regarding biomechanical gait measures.
- Aerobic Exercise with Task-Specific Training may be beneficial for improving aerobic measures and gait endurance after stroke when compared to Task-Specific Training Alone.
- Motivational Interviewing with Occupational Therapy may be beneficial for improving activities of daily living, but not quality of life, after stroke when compared to Occupational Therapy Alone; the literature is mixed regarding motor recovery.
- Specific PT protocol (Techniques aimed to strengthen sensitivity, movement dissociation and balance. Were added based on patients functional level) may not be beneficial for improving biomechanical balance measures and balance after stroke when compared to Conventional PT protocol.
- If-Then goal setting for exercise may not be beneficial for improving gait speed, functional mobility, and quality of life after stroke when compared to Goal setting.
- Cognitive therapy with graded activity training may be beneficial for improving gait endurance and quality of life, but not pain, after stroke when compared to Cognitive therapy.
- Team Care may not be beneficial for improving activities of daily living after stroke when compared to conventional care.
- Cross-training Physiotherapy may not be beneficial for improving biomechanical balance measures, gait speed, and functional mobility after stroke when compared to Conventional Physiotherapy.
- Range of Motion exercise program by themselves may be beneficial for improving pain after stroke when compared to Usual care.
- Range of Motion exercise program with physical help may be beneficial for improving pain after stroke when compared to Usual care.
- Muscle energy technique with conventional therapy may be beneficial for improving pain after stroke when compared to Conventional therapy.
- Neurac with conventional therapy may be beneficial for improving pain after stroke when compared to Conventional therapy.
- Moderate Intensity Interval Training may not be beneficial for improving motor recovery after stroke when compared to Reduced-Exertion High-Intensity Interval Training; Moderate Intensity Interval Training may result in lesser improvements in activities of daily living when compared to Reduced-Exertion High-Intensity Interval Training.

- High-intensity forward stepping training may be beneficial for improving gait speed and gait endurance, but not aerobic measures, functional mobility, and falls and fear of falling, after stroke when compared to Low-intensity variable stepping training; the literature is mixed regarding biomechanical gait measures.
- High-intensity variable stepping training may be beneficial for improving gait speed and gait endurance, but not aerobic measures, functional mobility, and falls and fear of falling, after stroke when compared to Low-intensity variable stepping training; the literature is mixed regarding biomechanical gait measures.
- Muscle energy technique with Neurac with conventional therapy may be beneficial for improving pain after stroke when compared to Conventional therapy.
- Low-to-Moderate Intensity Continuous Training or Moderate Intensity Interval Training may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional rehab.
- Reduced-Exertion High-Intensity Interval Training may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional rehab.

A.11 Balance Training (Table 11)

Key Points

- Balance-Focused Exercise Programs may be beneficial for improving motor recovery, biomechanical balance measures, functional mobility, and balance, but not sensory and proprioceptive function and activities of daily living, after stroke when compared to Conventional Rehabilitation; the literature is mixed regarding falls and fear of falling.
- Task Specific Balance Training may not be beneficial for improving biomechanical gait measures, activities of daily living, falls and fear of falling, and quality of life after stroke when compared to Upper Limb Exercise; the literature is mixed regarding functional mobility.
- Balance Training with Posture Changes may be beneficial for improving neurophysiological measures, but not activities of daily living, after stroke when compared to Balance Training; the literature is mixed regarding motor recovery and gait speed.
- Shoulder elevation posture change with balance training and Conventional training may be beneficial for improving motor recovery, neurophysiological measures, and gait speed, but not activities of daily living, after stroke when compared to Back posture change with balance training and Conventional training.
- Wobble Board Training may be beneficial for improving biomechanical balance measures, functional mobility, and balance after stroke when compared to Conventional Physiotherapy.
- Balance-Focused Exercise Programs may be beneficial for improving biomechanical balance measures, but not balance and falls and fear of falling, after stroke when compared to At-home Exercises.
- Balance Training Using SMART Balance Master may not be beneficial for improving motor recovery, biomechanical balance measures, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Conventional Rehabilitation.
- Non-Supportive Balance Trainers with Feedback may be beneficial for improving activities of daily living, gait endurance, functional mobility, and balance, but not muscle strength and falls and fear of falling, after stroke when compared to Conventional Therapy or Balance Training; the literature is mixed regarding biomechanical balance measures and sensory and proprioceptive function.
- Balance Training with Visual Biofeedback may be beneficial for improving motor recovery and falls and fear of falling, but not biomechanical gait measures, biomechanical balance measures, spasticity, activities of daily living, functional mobility, and balance, after stroke when compared to Conventional Therapy or Balance Training; the literature is mixed regarding range of motion and gait speed.
- Balance training with self- controlled postural control visual biofeedback may be beneficial for improving biomechanical balance measures after stroke when compared to Balance training with no control over postural control visual biofeedback.
- Standing Practice may be beneficial for improving biomechanical gait measures and functional mobility, but not motor recovery, activities of daily living, and balance, after stroke when compared to Conventional Therapy.

- Perturbation Balance Trainers with Feedback may be beneficial for improving muscle strength and balance, but not spasticity, activities of daily living, gait endurance, and functional mobility, after stroke when compared to Conventional Therapy or Balance Training; the literature is mixed regarding motor recovery and gait speed.
- Perturbation Balance Trainers may be beneficial for improving muscle strength and quality of life, but not biomechanical gait measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, after stroke when compared to Conventional Therapy or Balance Training; the literature is mixed regarding motor recovery, spasticity, and sensory and proprioceptive function.
- Visual Deprivation Group Balance Training Group with Conventional Therapy may be beneficial for improving biomechanical balance measures, but not balance, after stroke when compared to Visual Feedback Balance Training Group with Conventional Therapy.
- Balance Training with Visual Deprivation may be beneficial for improving biomechanical balance measures and activities of daily living, but not biomechanical gait measures, gait speed, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Balance Training with Visual Cues; the literature is mixed regarding balance.
- Visual cue deprivation with balance training and head control may be beneficial for improving balance, but not biomechanical gait measures and biomechanical balance measures, after stroke when compared to Visual cue deprivation with Balance training.
- Balance Training with Kinesthetic Ability Training Device may be beneficial for improving motor recovery and biomechanical balance measures, but not activities of daily living, after stroke when compared to Conventional Rehabilitation.
- Balance Training with Full Rest Periods may not be beneficial for improving balance after stroke when compared to Balance Training with Short Rest Periods.
- Balance Training with Muscle Vibration may not be beneficial for improving functional mobility and balance after stroke when compared to Conventional Rehabilitation; the literature is mixed regarding activities of daily living.
- Balance Training with Biofeedback may be beneficial for improving biomechanical balance measures, gait speed, and quality of life, but not motor recovery, activities of daily living, functional mobility, and balance, after stroke when compared to Balance Training.
- Vestibular Training may be beneficial for improving biomechanical balance measures, gait speed, functional mobility, and balance, but not biomechanical gait measures, muscle strength, activities of daily living, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy.
- Gaze stabilization exercises with balance exercises and neurodevelopmental treatment may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and functional mobility, but not balance and falls and fear of falling, after stroke when compared to gaze stabilization exercises with neurodevelopmental treatment.
- Robotic Balance Training may be beneficial for improving sensory and proprioceptive function and quality of life, but not motor recovery, biomechanical balance measures, muscle strength, activities of daily living, functional mobility, balance, and falls and fear of falling, after stroke when compared to Conventional Therapy.
- Trampoline Balance Training may be beneficial for improving balance, but not activities of daily living, gait endurance, and functional mobility, after stroke when compared to Stable Surface Balance Training.
- Ankle-Foot orthosis with Balance Training Shoes may be beneficial for improving aerobic measures and gait speed, but not functional mobility, after stroke when compared to Ankle-Foot Orthosis with Regular Shoes.
- Balance Training with transcutaneous electrical nerve stimulation may be beneficial for improving neurophysiological measures and balance after stroke when compared to Balance Training with Conventional Care.
- Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care may be beneficial for improving neurophysiological measures after stroke when compared to Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care; the literature is mixed regarding balance.

- Balance Training with Shoe Lift may be beneficial for improving biomechanical balance measures, but not balance and falls and fear of falling, after stroke when compared to Balance Training.
- Strength or Resistance Training with Balance Training may be beneficial for improving muscle strength, gait speed, gait endurance, and balance, but not motor recovery, neurophysiological measures, activities of daily living, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy.
- Structured Balance Awareness may be beneficial for improving balance and falls and fear of falling after stroke when compared to Health Awareness Program.
- Balance Training with Fresnel Prism Glasses may be beneficial for improving gait speed, gait endurance, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Balance and Walking Training.
- Sensory Balance Training may be beneficial for improving gait endurance, but not biomechanical balance measures, gait speed, functional mobility, and balance, after stroke when compared to Robot-assisted Stair Climbing.
- Sitting Balance Training with Sensory Input may be beneficial for improving functional mobility, balance, and quality of life after stroke when compared to Sitting Balance.
- External focus on balance board task may be beneficial for improving biomechanical balance measures, but not functional mobility, after stroke when compared to Internal focus on balance board task.
- Balance Training may be beneficial for improving gait speed, but not motor recovery, after stroke when compared to No Training; the literature is mixed regarding biomechanical gait measures.
- Vestibular rehabilitation may not be beneficial for improving biomechanical balance measures, activities of daily living, gait speed, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Convectional treatment.
- Progressive Balance Training may be beneficial for improving balance after stroke when compared to Balance Training.
- Perturbation Balance Training may not be beneficial for improving biomechanical gait measures and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation; the literature is mixed regarding functional mobility.
- Class-Based Body Awareness Training may not be beneficial for improving sensory and proprioceptive function, gait speed, and quality of life after stroke when compared to Home-Based Body Awareness Training; the literature is mixed regarding motor recovery.
- Visual Scanning Training with Task-Specific Activities may be beneficial for improving balance, but not activities of daily living, after stroke when compared to Task-Specific Activities Alone.
- Vestibular Training may be beneficial for improving functional mobility and quality of life after stroke when compared to Virtual Reality Training.
- Vestibular rehabilitation therapy + Conventional physical therapy may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Conventional care.
- Cognitive behaviour therapy + task-oriented balance training may be beneficial for improving activities of daily living, balance, and falls and fear of falling after stroke when compared to General health education + task-oriented balance training.
- Visual-spatial training exercises using specular vision training, mirror training, and target identification while walking + Conventional rehabilitation may be beneficial for improving activities of daily living and functional mobility, but not biomechanical balance measures and balance, after stroke when compared to Trunk stabilization and weight transfer exercises + Conventional rehabilitation.
- Vestibular rehabilitation + conventional PT may not be beneficial for improving functional mobility and balance after stroke when compared to conventional PT.
- Pro-Kin system with weight loss system (body-weight support) with balance training may be beneficial for improving functional mobility and balance after stroke when compared to Conventional balance training.
- Metronome training with core strengthening and general balance exercises may be beneficial for improving functional mobility after stroke when compared to Core strengthening with general balance exercises.

- Robot assisted gait training with Traditional balance training may not be beneficial for improving functional mobility, balance, and falls and fear of falling after stroke when compared to Traditonal balance training; the literature is mixed regarding motor recovery.
- Gait-slip perturbation with FES to paretic quadriceps muscle may be beneficial for improving biomechanical gait measures and falls and fear of falling after stroke when compared to Gait-slip perturbations.
- Treadmill gait and balance training with Traditional gait and balance training may not be beneficial for improving gait speed, functional mobility, and falls and fear of falling after stroke when compared to Traditional gait with balance training.
- Visual feedback with Unstable surface balance training may be beneficial for improving gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Conventional physical therapy; the literature is mixed regarding range of motion.
- Visual feedback with Unstable surface balance training may be beneficial for improving gait speed and balance, but not biomechanical gait measures and functional mobility, after stroke when compared to Unstable surface balance training; the literature is mixed regarding range of motion.
- Virtual balance training (VBT) with Conservative training may not be beneficial for improving motor recovery, spasticity, activities of daily living, balance, and quality of life after stroke when compared to Conservative training (traditional rehab techniques).
- The literature is mixed regarding the effect of Foot Mobilization with Intrinsic Foor Muscles Facilitation and (Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations) on biomechanical balance measures after stroke when compared to Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations.
- Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, balance, and falls and fear of falling after stroke when compared to Sham taping with exercise training.
- Visual feedback via Mirror with Verbal feedback and Conventional treatment (static and dynamic balance training) may be beneficial for improving balance after stroke when compared to Visual feedback via Mirror with Conventional treatment (static and dynamic balance training).
- Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may be beneficial for improving motor recovery, biomechanical balance measures, spasticity, and range of motion, but not balance, after stroke when compared to Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy; the literature is mixed regarding functional mobility.
- Virtual reality balance training with Nintendo Wii with conventional physical therapy may be beneficial for improving activities of daily living, functional mobility, and balance, but not motor recovery, after stroke when compared to Conventional physical therapy.
- Perturbation treadmill training group may be beneficial for improving balance, but not muscle strength, activities of daily living, gait speed, and falls and fear of falling, after stroke when compared to Non-perturbation treadmill training group.
- Balance Training with electromyography- triggered functional electrical stimulation and General Rehabilitation may be beneficial for improving neurophysiological measures, functional mobility, and balance after stroke when compared to Balance Training without functional electrical stimulation with General Rehabilitation.
- Trunk balance training on rocker board with conventional therapy may be beneficial for improving gait endurance and balance after stroke when compared to Trunk balance training on plain surface with conventional therapy.
- Modified PC Balance Training Gaming Platform may be beneficial for improving biomechanical balance measures, gait speed, and functional mobility after stroke when compared to PC gaming with Mouse; the literature is mixed regarding balance.
- Rehabilitation with Balance training and Visual biofeedback may not be beneficial for improving functional mobility and balance after stroke when compared to rehabilitation program with lateral wedge insole.

- Wii Fit-based balance exercise with conventional rehabilitation may be beneficial for improving biomechanical balance measures and balance, but not functional mobility, after stroke when compared to Conventional rehabilitation; the literature is mixed regarding activities of daily living.
- Progressive resistance with balance training and motivational session may not be beneficial for improving motor recovery, neurophysiological measures, and balance after stroke when compared to Usual activity; the literature is mixed regarding activities of daily living.
- Virtual reality balance training with treatment may not be beneficial for improving activities of daily living, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to treatment.
- Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy may be beneficial for improving balance, but not gait endurance and quality of life, after stroke when compared to C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy; the literature is mixed regarding functional mobility.
- Tetrax biofeedback balance training with Conventional care may be beneficial for improving sensory and proprioceptive function after stroke when compared to Conventional care; the literature is mixed regarding biomechanical balance measures, muscle strength, and functional mobility.
- Dynamic balance training with Balance Trainer may be beneficial for improving activities of daily living, functional mobility, and balance after stroke when compared to Static balance training with a conventional standing frame.
- Computer-generated interactive visual feedback balance training with Physical therapy may be beneficial for improving motor recovery and balance after stroke when compared to Mirror visual feedback balance training with Physical therapy.
- Balance training with cognitive training may not be beneficial for improving motor recovery, activities of daily living, and balance after stroke when compared to Balance training with balance board.
- Wii-based balance training may not be beneficial for improving activities of daily living, functional mobility, balance, and falls and fear of falling after stroke when compared to Progressive balance training.
- Contemporary Bobath Concept Approach with early sitting, standing, and walking strategies with balance training may be beneficial for improving functional mobility and balance after stroke when compared to Contemporary Bobath Concept Approach.
- Ankle Foot Orthosis (Joint type) with Balance Training may not be beneficial for improving biomechanical balance measures after stroke when compared to No Orthotic with Balance Training; the literature is mixed regarding neurophysiological measures.
- Video Game-Based Balance Training with conventional physical therapy may be beneficial for improving activities of daily living and balance, but not gait speed and functional mobility, after stroke when compared to Conventional physical therapy with Balance Training.
- Wii Fit Plus video game (Balance training) may be beneficial for improving biomechanical balance measures, but not functional mobility, balance, and falls and fear of falling, after stroke when compared to Wii Sports video game (Upper limb training).
- Wii-based balance training may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, and activities of daily living after stroke when compared to Conventional rehabilitation; the literature is mixed regarding functional mobility and balance.
- Standing balance exercises with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Usual care.
- The literature is mixed regarding the effect of Balance training with cognitive training on biomechanical balance measures after stroke when compared to Balance training.
- Dual-task balance training may be beneficial for improving gait speed after stroke when compared to Single-task balance training; the literature is mixed regarding biomechanical balance measures.
- Wii-based balance training may be beneficial for improving functional mobility and balance, but not activities of daily living, after stroke when compared to Control group.
- Balance training with Balance Control Trainer may be beneficial for improving functional mobility and balance, but not muscle strength and activities of daily living, after stroke when compared to Conventional rehabilitation.

- 3D balance exercises (3D Thera-Balance) with visual feedback may be beneficial for improving balance, but not gait speed, after stroke when compared to Weight shifting exercises.
- Virtual reality-based balance training may be beneficial for improving functional mobility and balance, but not biomechanical gait measures and biomechanical balance measures, after stroke when compared to Conventional therapy; the literature is mixed regarding gait speed.
- Visual biofeedback providing posture information may be beneficial for improving biomechanical balance measures after stroke when compared to Standing without biofeedback.
- Pressure sensor-based vibrotactile biofeedback may be beneficial for improving biomechanical balance measures after stroke when compared to Visual biofeedback providing posture information.

A.12 Stretching or Mobilization Exercises (Table 12)

Key Points

- Functional Stretching may be beneficial for improving gait speed, but not muscle strength, spasticity, range of motion, and neurophysiological measures, after stroke when compared to Conventional Therapy.
- Mobilization Therapy or Placebo may be beneficial for improving motor recovery, biomechanical gait measures, biomechanical balance measures, muscle strength, range of motion, activities of daily living, functional mobility, balance, and quality of life, but not pain, after stroke when compared to Conventional Therapy or Placebo; the literature is mixed regarding spasticity, neurophysiological measures, and gait speed.
- Manual therapy with task oriented training and home exercise program may be beneficial for improving range of motion, but not gait speed, functional mobility, balance, and quality of life, after stroke when compared to task oriented training with home exercise program.
- Sustained natural apophyseal glides with neurodevelopmental techniques may not be beneficial for improving biomechanical balance measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Maitland mobilization with neurodevelopmental techniques.
- Joint mobilization with acupuncture may not be beneficial for improving range of motion, pain, activities of daily living, and gait speed after stroke when compared to Joint mobilization.
- Early and Intense Mobilization may not be beneficial for improving motor recovery, aerobic measures, activities of daily living, functional mobility, and balance after stroke when compared to Care.
- Joint mobilization may result in lesser improvements in biomechanical gait measures and gait speed when compared to Joint mobilization with active stretching; the literature is mixed regarding range of motion.
- Active Stretching may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Joint mobilization with active stretching; the literature is mixed regarding range of motion.
- Mobilization With Movement may be beneficial for improving biomechanical gait measures, balance, and falls and fear of falling after stroke when compared to Muscle Stretching; the literature is mixed regarding range of motion and gait speed.
- Self-ankle mobilization with rehabilitation may not be beneficial for improving activities of daily living after stroke when compared to Self-ankle mobilization with 10-degree inclined board with rehabilitation; Self-ankle mobilization with rehabilitation may result in lesser improvements in range of motion and gait speed when compared to Self-ankle mobilization with 10-degree inclined board with rehabilitation; the literature is mixed regarding biomechanical gait measures and balance.
- Dynamic Stretching (Tai Chi, Yoga, Pilates) may be beneficial for improving motor recovery, activities of daily living, and balance, but not muscle strength, range of motion, gait endurance, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Conventional or No Therapy; the literature is mixed regarding biomechanical balance measures and gait speed.
- Daoyin with Conventional rehab may not be beneficial for improving motor recovery and balance after stroke when compared to Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab; the literature is mixed regarding activities of daily living.

- Dynamic Stretching may be beneficial for improving falls and fear of falling, but not muscle strength, functional mobility, balance, and quality of life, after stroke when compared to SilverSneaker exercises or Usual care.
- Tai Chi may not be beneficial for improving muscle strength, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to SilverSneakers exercises.
- Body Weight Supported Dynamic Stretching may be beneficial for improving motor recovery and falls and fear of falling, but not biomechanical gait measures, biomechanical balance measures, gait speed, and balance, after stroke when compared to Conventional Therapy.
- Early Proprioceptive Neuromuscular Facilitation may not be beneficial for improving muscle strength, activities of daily living, and gait endurance after stroke when compared to late Proprioceptive Neuromuscular Facilitation.
- Baduanjin Training may be beneficial for improving functional mobility and balance, but not activities of daily living, falls and fear of falling, and quality of life, after stroke when compared to Conventional Exercise; the literature is mixed regarding biomechanical balance measures.
- Proprioceptive Neuromuscular Facilitation may be beneficial for improving balance, but not muscle strength, after stroke when compared to Conventional Therapy; the literature is mixed regarding range of motion.
- Proprioceptive Neuromuscular Facilitation with Custom Exercises may not be beneficial for improving muscle strength and activities of daily living after stroke when compared to Custom Exercises Alone.
- Proprioceptive Neuromuscular Facilitation with virtual reality may not be beneficial for improving motor recovery, sensory and proprioceptive function, and balance after stroke when compared to proprioceptive neuromuscular facilitation or virtual reality Alone.
- Proprioceptive Neuromuscular Facilitation with Electrical Stimulation may not be beneficial for improving functional mobility and balance after stroke when compared to proprioceptive neuromuscular facilitation Alone.
- Technology-Assisted Ankle Stretcher may be beneficial for improving biomechanical balance measures and range of motion, but not biomechanical gait measures and gait speed, after stroke when compared to Stretching Board.
- Isotonic muscle stretch with weight bearing may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Healthy isotonic muscle stretch with weight bearing or Healthy isotonic stretch without weight bearing or Healthy isokinetic stretch.
- Ankle Range of Motion Training may not be beneficial for improving muscle strength, spasticity, activities of daily living, gait endurance, functional mobility, balance, and quality of life after stroke when compared to No Treatment; the literature is mixed regarding gait speed.
- Stretching in a Supine Position may be beneficial for improving spasticity and neurophysiological measures after stroke when compared to Stretching in a Seated Position.
- Proprioceptive neuromuscular facilitation-Based Gait Training may be beneficial for improving balance, but not biomechanical gait measures, gait speed, and functional mobility, after stroke when compared to Conventional Gait Training.
- Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques may be beneficial for improving muscle strength, gait speed, functional mobility, and balance after stroke when compared to Talocrural joint only mobilization with neurodevelopmental techniques.
- Peripheral Nerve Mobilization with virtual reality-Based Gait Training may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Conventional Exercises.
- Chiropractic spinal adjustments + Physical Therapy may be beneficial for improving motor recovery, but not activities of daily living, functional mobility, and quality of life, after stroke when compared to Sham chiropractic + physical therapy.
- Tai Chi Yunshou may be beneficial for improving motor recovery, but not activities of daily living, functional mobility, and balance, after stroke when compared to Common Balance Rehabilitation Therapy; the literature is mixed regarding falls and fear of falling.
- Tai Chi Chuan exercises may not be beneficial for improving functional mobility, balance, and quality of life after stroke when compared to Conventional care physiotherapy.

- Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises may be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to Sham Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises.
- Ankle Kinesio taping may result in lesser improvements in biomechanical gait measures, range of motion, and gait speed when compared to Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (proprioceptive neuromuscular facilitation-KT).
- Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may be beneficial for improving balance and quality of life, but not gait speed, after stroke when compared to Convetional physiotherapy.
- Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may be beneficial for improving balance and quality of life, but not gait speed, after stroke when compared to Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy.
- Baduanjin exercise training with Health education program may be beneficial for improving motor recovery, muscle strength, gait speed, and balance, but not biomechanical gait measures and spasticity, after stroke when compared to Health education program.
- Robot assisted ankle stretching device (Beijing LTK Science and Technology Co., Ltd., Beijing, China) may not be beneficial for improving motor recovery, muscle strength, spasticity, range of motion, activities of daily living, and balance after stroke when compared to Manual stretching by the appointed physiotherapist.
- Task-specific training may be beneficial for improving spasticity, functional mobility, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Virtual Reality (Nintendo Wii) may not be beneficial for improving motor recovery, sensory and proprioceptive function, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Virtual Reality (Nintendo Wii) may not be beneficial for improving motor recovery after stroke when compared to Virtual Reality with Proprioceptive Neuromuscular Facilitation.
- Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may be beneficial for improving gait speed, gait endurance, and functional mobility after stroke when compared to Sham taping with treadmill training.
- Robotic ankle stretching exercises may be beneficial for improving biomechanical balance measures and range of motion, but not biomechanical gait measures and gait speed, after stroke when compared to Conventional stretching board 2d/wk, for 3.5wks (7 sessions total).
- Whole Body Vibration (40 hz,4 mm) with Exercise (Stretching and active ROM exercise) may be beneficial for improving gait speed, but not spasticity and activities of daily living, after stroke when compared to Sham Vibration with Exercise (Stretching and active ROM exercise).
- Extracorporeal Shock Wave Therapy with stretching and Oral anti-spastic drugs may not be beneficial for improving spasticity, range of motion, pain, and gait speed after stroke when compared to stretching with Oral anti-spastic drugs.
- Neurodevelopmental Bobath Concept Approach may be beneficial for improving biomechanical gait measures after stroke when compared to proprioceptive neuromuscular facilitation method (proprioceptive neuromuscular facilitation).
- Aquatic therapy (based on proprioceptive neuromuscular facilitation) may be beneficial for improving activities of daily living, functional mobility, and balance after stroke when compared to Proprioceptive neuromuscular facilitation on the ground.
- Aquatic therapy (based on proprioceptive neuromuscular facilitation) may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to Conventional therapy.
- Performance-based training with Anklebot stretching may be beneficial for improving gait speed, but not muscle strength, range of motion, activities of daily living, and balance, after stroke when compared to Manual stretching of ankle; the literature is mixed regarding biomechanical gait measures.
- Stretching exercise with wearing toe spreader may not be beneficial for improving biomechanical gait measures, spasticity, gait speed, and balance after stroke when compared to No Orthotic (conventional care).

- Robot assisted passive stretching and active movement training may be beneficial for improving biomechanical gait measures, muscle strength, spasticity, functional mobility, and balance, but not gait endurance, after stroke when compared to At-home passive ankle stretching; the literature is mixed regarding range of motion.
- Therapeutic ultrasound with passive stretching exercise may not be beneficial for improving motor recovery, spasticity, range of motion, and neurophysiological measures after stroke when compared to Passive stretching exercise.
- Botulinum toxin A (100U) with Serial casting and stretching and gait training may be beneficial for improving spasticity and range of motion, but not muscle strength, gait speed, gait endurance, and functional mobility, after stroke when compared to Botulinum toxin A (100U) with Taping and stretching and gait training.
- Task-specific training with Ankle joint mobilizations may be beneficial for improving range of motion, but not biomechanical gait measures, after stroke when compared to Task-specific training; the literature is mixed regarding biomechanical balance measures and functional mobility.
- Botulinum toxin A (500U) with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, spasticity, and range of motion after stroke when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching.
- Lower Limb Robot with Conventional rehab may not be beneficial for improving motor recovery, activities of daily living, and balance after stroke when compared to Daoyin with Lower Limb Robot with Conventional rehab.
- Conventional exercises may not be beneficial for improving biomechanical balance measures after stroke when compared to No treatment.
- Tai Chi may be beneficial for improving falls and fear of falling, but not muscle strength, balance, and quality of life, after stroke when compared to Usual care.
- SilverSneakers exercises may not be beneficial for improving falls and fear of falling, muscle strength, balance, and quality of life after stroke when compared to Usual care.
- Ankle Kinesio taping may be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to No Taping.
- Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (PNF-KT) may be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to No Taping.

A.13 Orthotic Devices (Table 13)

Key Points

- Anterior Kinesio Taping may be beneficial for improving balance, but not functional mobility, after stroke when compared to Posterior Kinesio Taping.
- Taping may be beneficial for improving muscle strength and neurophysiological measures, but not falls and fear of falling, activities of daily living, and spasticity, after stroke when compared to no taping, sham taping, or conventional therapy; the literature is mixed regarding biomechanical balance measures, gait speed, balance, biomechanical gait measures, range of motion, functional mobility, and gait endurance.
- Extensor Digitorum Longus Taping may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Tibialis Anterior Taping.
- Pelvic stability training with posterior and lateral taping may be beneficial for improving muscle strength, but not gait speed, after stroke when compared to Pelvic stability training with posterior taping only; the literature is mixed regarding biomechanical gait measures.
- Posterior pelvic tilt taping with functional movements (sitting-to- standing, indoor walking and stair walking training) may be beneficial for improving biomechanical gait measures, muscle strength, and gait speed after stroke when compared to Functional movements (sitting-to-standing with indoor walking and stair walking training).

- Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT) may be beneficial for improving gait endurance, functional mobility, and gait speed after stroke when compared to Sham taping with treadmill training.
- Walking with TheraTogs may be beneficial for improving neurophysiological measures, but not gait speed, after stroke when compared to Walking with cane at normal height.
- Walking with hip abductor taping may not be beneficial for improving gait speed after stroke when compared to Walking with cane at normal height; the literature is mixed regarding neurophysiological measures.
- Ankle Kinesio taping may result in lesser improvements in biomechanical gait measures, range of motion, and gait speed when compared to Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (proprioceptive neuromuscular facilitation-KT).
- Taping With Electrical Stimulation may be beneficial for improving muscle strength, spasticity, and gait speed after stroke when compared to Electrical Stimulation or Taping Alone or No Taping.
- New Body Orthosis may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to No Orthosis.
- Shoe Insole Orthotics During Walking may be beneficial for improving functional mobility and balance, but not biomechanical gait measures, biomechanical balance measures, range of motion, and gait speed, after stroke when compared to Overground Walking or Conventional Therapy or Sham.
- Rehabilitation with Balance training and Visual biofeedback may not be beneficial for improving functional mobility and balance after stroke when compared to rehabilitation program with lateral wedge insole.
- Weight-Shift Therapy Using Shoe Insert may be beneficial for improving biomechanical balance measures, but not motor recovery, biomechanical gait measures, gait speed, and balance, after stroke when compared to Conventional Treatment.
- Ankle-Foot Orthosis may be beneficial for improving motor recovery and functional mobility, but not biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, gait speed, gait endurance, and balance, after stroke when compared to No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis; the literature is mixed regarding neurophysiological measures and aerobic measures.
- Ankle-Foot Orthosis with Botulinum Toxin may be beneficial for improving biomechanical gait measures and spasticity, but not gait speed, after stroke when compared to Botulinum Toxin.
- Taping with Botulinum Toxin may not be beneficial for improving biomechanical gait measures, spasticity, range of motion, and gait speed after stroke when compared to Botulinum Toxin.
- Early Ankle Foot Orthosis may be beneficial for improving activities of daily living and balance, but not gait speed, gait endurance, and functional mobility, after stroke when compared to Late Ankle Foot Orthosis.
- High PFR DAFO may not be beneficial for improving biomechanical gait measures and biomechanical balance measures after stroke when compared to Medium PFR DAFO or Low PFR Dynamic Ankle-Foot Orthosis (DAFO); High PFR DAFO may result in lesser improvements in range of motion and gait speed when compared to Medium PFR DAFO or Low PFR Dynamic Ankle-Foot Orthosis (DAFO).
- Low PFR Dynamic Ankle-Foot Orthosis (DAFO) may not be beneficial for improving biomechanical gait measures and biomechanical balance measures after stroke when compared to Medium PFR DAFO; Low PFR Dynamic Ankle-Foot Orthosis (DAFO) may result in lesser improvements in range of motion and gait speed when compared to Medium PFR DAFO.
- Carbon composite ankle-foot orthosis may not be beneficial for improving gait speed and functional mobility after stroke when compared to Posterior leaf spring ankle-foot orthosis.
- A Comparison of Orthoses may not be beneficial for improving biomechanical balance measures, muscle strength, spasticity, pain, activities of daily living, gait endurance, functional mobility, balance, and falls and fear of falling after stroke when compared to Oil Damper ankle-foot orthosis with Gait training; the literature is mixed regarding biomechanical gait measures, range of motion, and gait speed.
- Ankle-foot orthosis-PlfS with shoe (SSh) may not be beneficial for improving biomechanical gait measures and range of motion after stroke when compared to SSh only.
- AFO-plfR may be beneficial for improving biomechanical gait measures, but not range of motion, after stroke when compared to SSh only.

- AFO-PlfS with Standard shoe (SSh) may not be beneficial for improving biomechanical gait measures and range of motion after stroke when compared to AFO-plfR.
- The literature is mixed regarding the effect of Ankle-foot orthosis with mechanical plantar flexion stops (ankle-foot orthosis-PlfS) with Rocker shoe (RSh) on biomechanical gait measures after stroke when compared to ankle-foot orthosis-PlfS with shoe (SSh).
- Solid Ankle Foot Orthosis may not be beneficial for improving biomechanical gait measures after stroke when compared to Dynamic Ankle Foot Orthosis.
- Plastic ankle foot orthosis made with polypropylene may not be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to Hybrid ankle foot orthosis made with polypropylene covered with canvas fabric.
- Using an off-the-shelf carbon ankle-foot orthosis (C- ankle-foot orthosis) may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Using a custom plastic ankle-foot orthosis (P-ankle-foot orthosis).
- 5-degree lateral wedge orthotic in both shoes may not be beneficial for improving muscle strength and gait speed after stroke when compared to 8.5-degree lateral wedge orthotic in both shoes.
- Anterior ankle foot orthosis may be beneficial for improving neurophysiological measures, but not range of motion, after stroke when compared to Posterior ankle foot orthosis; the literature is mixed regarding gait speed and biomechanical gait measures.
- Bivalve Cast may not be beneficial for improving spasticity, range of motion, and activities of daily living after stroke when compared to Pressure-Relieving Ankle-Foot Orthosis or Conventional Care.
- Toe Spreader may not be beneficial for improving biomechanical gait measures, spasticity, gait speed, and balance after stroke when compared to Conventional Care.
- Comparing Types of Canes may not be beneficial for improving biomechanical gait measures, activities of daily living, gait speed, functional mobility, balance, gait endurance, and quality of life after stroke when compared to Ambulation therapy with cane with Conventional therapy.
- Single-point cane may be beneficial for improving aerobic measures, gait speed, and gait endurance after stroke when compared to Quad cane.
- Neuromuscular electrical stimulation Orthosis may be beneficial for improving gait speed, but not motor recovery, muscle strength, spasticity, and activities of daily living, after stroke when compared to Ankle-Foot Orthosis; the literature is mixed regarding functional mobility.
- Ankle-Foot Orthosis with Balance Training Shoes may be beneficial for improving aerobic measures and gait speed, but not functional mobility, after stroke when compared to Ankle-Foot Orthosis with Regular Shoes.
- Nighttime splint wearing with Inpatient rehabilitation may not be beneficial for improving range of motion and functional mobility after stroke when compared to Standing on a tilt table with Inpatient rehabilitation.
- Arm Sling may be beneficial for improving balance, but not biomechanical gait measures, muscle strength, aerobic measures, pain, and gait speed, after stroke when compared to No Therapy; the literature is mixed regarding gait endurance.
- Wearable Devices may be beneficial for improving activities of daily living and balance, but not biomechanical gait measures, after stroke when compared to Conventional Care or No Therapy; the literature is mixed regarding gait speed.
- Oswestry standing frame treatment may not be beneficial for improving motor recovery, activities of daily living, and functional mobility after stroke when compared to Usual treatment.
- Treadmill Training with Orthotic Devices may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and motor recovery after stroke when compared to Treadmill Training Alone; the literature is mixed regarding balance.
- Visual Biofeedback with Orthotic Devices may be beneficial for improving spasticity, but not range of motion, after stroke when compared to Sham Feedback; the literature is mixed regarding gait speed.
- Regent Suit may be beneficial for improving neurophysiological measures, but not motor recovery, activities of daily living, and balance, after stroke when compared to Conventional Therapy.
- Knee immobilizer brace may result in lesser improvements in balance when compared to Knee immobilizer brace with Foot lifter orthosis.

- Knee immobilizer brace may not be beneficial for improving balance after stroke when compared to Knee immobilizer brace with Rigid taping.
- Knee immobilizer brace with Foot lifter orthosis may be beneficial for improving balance after stroke when compared to Knee immobilizer brace with Rigid taping.
- Knee Orthosis with Gait Training may be beneficial for improving biomechanical gait measures, but not gait speed, after stroke when compared to Gait Training Alone.
- Physical Therapy Wearing Insole (unaffected side) may not be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and falls and fear of falling after stroke when compared to Physical Therapy.
- Arm sling may be beneficial for improving aerobic measures and gait speed after stroke when compared to No Treatment.
- Wearing an Inhibitor Hand Splint during ambulation may not be beneficial for improving balance after stroke when compared to no treatment; the literature is mixed regarding functional mobility.
- Gait training (with insole on non-paretic foot) may be beneficial for improving biomechanical gait measures and gait speed, but not gait endurance, after stroke when compared to Gait training (without insole).
- Shoulder brace during treadmill training may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to conventional treadmill training.
- Unstable board intervention (using AIREX Balance-pad) under non-paralyzed lower leg with Knee ankle foot orthosis (KAFO) on paralyzed leg and Usual physical therapy may be beneficial for improving biomechanical balance measures after stroke when compared to Usual Physical Therapy.
- Robot-assisted gait training (Welwalk orthosis-type robotic leg) with Conventional rehab may not be beneficial for improving motor recovery, activities of daily living, gait speed, gait endurance, and functional mobility after stroke when compared to Conventional rehab.
- Bicephalic transcranial direct current stimulation with gait training and foot drop stimulator (Walkaide orthosis) may not be beneficial for improving motor recovery, neurophysiological measures, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with gait training and foot drop stimulator.
- Ankle foot orthosis with gait training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility, but not aerobic measures, after stroke when compared to functional electrical stimulation with gait training.
- Cryo-airflow therapy for calf muscle with Physical therapy and Ankle foot orthosis at night may be beneficial for improving spasticity and range of motion, but not neurophysiological measures, after stroke when compared to Physical therapy with Ankle foot orthosis.
- Solid Ankle-foot orthosis, then Rocker shoes may be beneficial for improving aerobic measures and gait speed, but not functional mobility, after stroke when compared to Solid Ankle-foot orthosis, then Regular shoes.
- The literature is mixed regarding the effect of Botulinum toxin A under ultrasound guidance with ankle foot orthosis (ankle-foot orthosis) and Conventional rehabilitation on motor recovery, spasticity, activities of daily living, and balance after stroke when compared to Conventional rehabilitation.
- Gait training with robotic leg brace may not be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Group exercise without robotic leg brace.
- 6wk of Peroneal nerve functional electrical stimulation (WalkAide Foot-Drop Stimulator) followed by 6wk of Ankle Foot Orthosis ; (ankle-foot orthosis) may not be beneficial for improving aerobic measures, gait speed, and functional mobility after stroke when compared to Ankle Foot Orthosis only or 12wk ankle-foot orthosis.
- Botulinum toxin A (100U) with Serial casting and stretching and gait training may be beneficial for improving spasticity and range of motion, but not muscle strength, gait speed, gait endurance, and functional mobility, after stroke when compared to Botulinum toxin A (100U) with Taping and stretching and gait training.
- Botulinum toxin A (75- 100U) with Kinesio Taping and home exercises may not be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to Botulinum toxin A (75- 100U) with Sham taping and home exercises.

- Botulinum toxin A (500U) with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, spasticity, and range of motion after stroke when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching.
- Odstock Dropped-foot Stimulator (peroneal nerve functional electrical stimulation) may not be beneficial for improving functional mobility after stroke when compared to No Intervention.
- Tibial nerve block through thermocoagulation with ankle-foot orthosis may not be beneficial for improving motor recovery, spasticity, gait speed, and quality of life after stroke when compared to Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis.
- Ankle Kinesio taping may be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to No Taping.
- Lower-leg KT using the concept of Proprioceptive neuromuscular facilitation Kinesio taping (PNF-KT) may be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to No Taping.
- Anterior Kinesio Taping may be beneficial for improving balance after stroke when compared to Standard physiotherapy.
- Posterior Kinesio Taping may be beneficial for improving balance after stroke when compared to Standard physiotherapy.
- Plastic ankle foot orthosis made with polypropylene may be beneficial for improving gait speed, but not biomechanical gait measures, after stroke when compared to Barefoot.
- Hybrid ankle foot orthosis made with polypropylene covered with canvas fabric may not be beneficial for improving gait speed and biomechanical gait measures after stroke when compared to Barefoot.
- Using an off-the-shelf carbon ankle-foot orthosis (C- AFO) may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to No ankle-foot orthosis.
- Using a custom plastic ankle-foot orthosis (P-AFO) may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to No ankle-foot orthosis.
- 5-degree lateral wedge orthotic in both shoes may not be beneficial for improving muscle strength and gait speed after stroke when compared to Overground walking with no wedge.
- Pressure-relieving Ankle- foot Orthosis with Physical Therapy may not be beneficial for improving spasticity, range of motion, and activities of daily living after stroke when compared to Physical Therapy.
- Customized unilateral ankle-foot orthosis may be beneficial for improving functional mobility after stroke when compared to No Intervention.
- 8.5-degree lateral wedge orthotic in both shoes may be beneficial for improving muscle strength, but not gait speed, after stroke when compared to Overground walking with no wedge.
- Walking with hip abductor taping may not be beneficial for improving neurophysiological measures after stroke when compared to Walking with TheraTogs.
- C-AFO ("off the shelf" composite AFO) or P-AFO (custom made plastic AFO) may be beneficial for improving biomechanical gait measures, range of motion, aerobic measures, gait speed, and gait endurance after stroke when compared to No treatment (No AFO, shoes only).
- C-AFO ("off the shelf" composite AFO) may not be beneficial for improving biomechanical gait measures, range of motion, aerobic measures, gait speed, and gait endurance after stroke when compared to P-AFO (custom made plastic AFO).

A.14 Hippotherapy (Table 14)

Key Points

- Hippotherapy Therapy or No Treatment may be beneficial for improving neurophysiological measures, gait speed, gait endurance, and balance, but not functional mobility, after stroke when compared to Conventional Therapy or No Treatment; the literature is mixed regarding biomechanical gait measures and activities of daily living.

- Hippotherapy Training Therapy may not be beneficial for improving motor recovery, biomechanical balance measures, muscle strength, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Trunk Training Therapy.
- Hippotherapy Training may be beneficial for improving biomechanical gait measures and gait speed, but not balance, after stroke when compared to Treadmill Training.
- Horse riding therapy may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility, but not gait endurance, after stroke when compared to Wait list control.
- Rhythm-and music based therapy may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Wait list control.

A.15 Biofeedback (Table 15)

Key Points

- Gait Training with Visual Feedback may be beneficial for improving biomechanical gait measures and activities of daily living, but not motor recovery, muscle strength, range of motion, gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, after stroke when compared to Gait Training or Conventional Therapy.
- Treadmill Training with Visual Biofeedback may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, range of motion, activities of daily living, gait speed, and functional mobility after stroke when compared to Treadmill Training; the literature is mixed regarding gait endurance and balance.
- Gait Training with Activity Feedback may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and quality of life after stroke when compared to Gait Training or Conventional Therapy; the literature is mixed regarding functional mobility.
- Gait Training with Postural Control Visual Feedback may be beneficial for improving biomechanical gait measures, but not biomechanical balance measures, muscle strength, aerobic measures, functional mobility, balance, and quality of life, after stroke when compared to Gait Training or electromyography Biofeedback; the literature is mixed regarding gait speed.
- Trunk Training with Visual Biofeedback may be beneficial for improving gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Conventional Therapy; the literature is mixed regarding muscle strength.
- Rehabilitation with electromyography biofeedback may be beneficial for improving neurophysiological measures, but not motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, sensory and proprioceptive function, activities of daily living, gait speed, and gait endurance, after stroke when compared to Conventional Therapy; the literature is mixed regarding biomechanical balance measures and functional mobility.
- Constant-force electromyography- biofeedback Tibalis anterior training with general Physiotherapy may not be beneficial for improving muscle strength, gait speed, gait endurance, and functional mobility after stroke when compared to Variable-force electromyography- biofeedback Tibalis anterior training with general Physiotherapy; the literature is mixed regarding biomechanical balance measures.
- Galvanic vestibular stimulation may not be beneficial for improving balance after stroke when compared to Lokomat gait training or Physiotherapy with visual feedback.
- The literature is mixed regarding the effect of Lokomat gait training on balance after stroke when compared to Physiotherapy with visual feedback.
- Balance Training with Computer-based Visual Feedback may be beneficial for improving motor recovery and balance after stroke when compared to Mirror Feedback.
- Cycling Training with Biofeedback may be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Conventional Rehabilitation.
- Overground Gait Training with Auditory Feedback may be beneficial for improving biomechanical gait measures, neurophysiological measures, and gait speed, but not gait endurance, functional mobility, and balance, after stroke when compared to Gait Training.

- Gait training with auditory feedback caused by active weight bearing on their paralyzed foot may be beneficial for improving biomechanical balance measures, gait speed, and functional mobility after stroke when compared to General gait training over the ground.
- Verbal Cues and Feedback During Walking may be beneficial for improving gait speed, but not biomechanical gait measures and neurophysiological measures, after stroke when compared to Tactile Cues and Feedback During Walking.
- Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy may be beneficial for improving muscle strength, gait speed, functional mobility, balance, and quality of life after stroke when compared to Sit-to-stand Training with physiotherapy.
- Standing postural symmetry training with a visual and auditory biofeedback trainer with repetitive sit-to-stand training and conventional rehabilitation may not be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Conventional rehabilitation.
- Balance Training with Biofeedback may be beneficial for improving biomechanical balance measures, range of motion, sensory and proprioceptive function, gait speed, functional mobility, and balance, but not biomechanical gait measures and activities of daily living, after stroke when compared to Balance Training or Conventional Therapy; the literature is mixed regarding motor recovery and muscle strength.
- Visual feedback with Unstable surface balance training may be beneficial for improving functional mobility and balance, but not biomechanical gait measures and gait speed, after stroke when compared to Unstable surface balance training; the literature is mixed regarding range of motion.
- Rehabilitation with Balance training and Visual biofeedback may not be beneficial for improving functional mobility and balance after stroke when compared to rehabilitation program with lateral wedge insole.
- Target or Reach Visual Feedback Training may be beneficial for improving biomechanical balance measures and neurophysiological measures, but not gait speed and balance, after stroke when compared to Conventional Rehabilitation.
- Strength Training with Visual Feedback may be beneficial for improving motor recovery and muscle strength, but not gait speed and balance, after stroke when compared to Physical Therapy; the literature is mixed regarding sensory and proprioceptive function.
- Perceptual Feedback may be beneficial for improving balance, but not biomechanical balance measures, after stroke when compared to Conventional Treatment.
- Robot-Assisted Gait Training with Biofeedback may be beneficial for improving neurophysiological measures, but not biomechanical gait measures, spasticity, pain, activities of daily living, functional mobility, balance, and quality of life, after stroke when compared to No Biofeedback or Conventional Biofeedback; the literature is mixed regarding motor recovery.
- Visual Biofeedback with Orthotic Devices may be beneficial for improving spasticity, but not range of motion, after stroke when compared to Sham Feedback; the literature is mixed regarding gait speed.
- Neurofeedback may be beneficial for improving biomechanical gait measures, sensory and proprioceptive function, gait speed, and functional mobility after stroke when compared to Sham.
- Knowledge of Results (Real-time visual feedback) may not be beneficial for improving motor recovery, gait speed, balance, and falls and fear of falling after stroke when compared to Knowledge of Performance (Real-time feedback with instructions on how to adjust/ direct cues); the literature is mixed regarding biomechanical balance measures.
- Electromyography Biofeedback During Single Support Phase may be beneficial for improving activities of daily living, functional mobility, and balance after stroke when compared to Stance Phase.
- Weight support feedback cane (WSFC) gait training + conventional care may be beneficial for improving biomechanical gait measures and neurophysiological measures, but not gait speed, after stroke when compared to Regular cane gait training + conventional care.
- 100% performance feedback and scatter plot visual feedback may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to No performance feedback.
- Multimodal training: Biofeedback FES +cycling training + biofeedback platform-based balance training + conventional rehabilitation may not be beneficial for improving biomechanical gait measures, muscle strength, activities of daily living, gait speed, gait endurance, balance, and falls and fear of falling after stroke when compared to Conventional rehabilitation.

- EMG biofeedback from the affected-side soleus muscle (EMG) may not be beneficial for improving biomechanical gait measures, range of motion, and gait speed after stroke when compared to Physical therapy (PT).
- Visual Deprivation Group Balance Training Group with Conventional Therapy may be beneficial for improving biomechanical balance measures, but not balance, after stroke when compared to Conventional Therapy.
- Visual Deprivation Group Balance Training Group with Conventional Therapy may be beneficial for improving biomechanical balance measures and functional mobility after stroke when compared to Visual Feedback Balance Training Group with Conventional Therapy.
- Dynamic sitting excercises in the mediolateral and anteroposterior directions with computer visual feedback with 500 (ms) delay may not be beneficial for improving motor recovery, neurophysiological measures, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Dynamic sitting excercises in the mediolateral and anteroposterior directions with computer visual feedback in real time.
- Pressure sensor-based vibrotactile biofeedback may be beneficial for improving biomechanical balance measures and gait speed after stroke when compared to Standing without biofeedback.
- Visual feedback via Mirror with Verbal feedback and Conventional treatment (static and dynamic balance training) may be beneficial for improving balance after stroke when compared to Visual feedback via Mirror with Conventional treatment (static and dynamic balance training).
- Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy may be beneficial for improving motor recovery, biomechanical balance measures, spasticity, and range of motion, but not balance, after stroke when compared to Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy; the literature is mixed regarding functional mobility.
- Whole-Body Tilting Postural Training (Visual feedback monitor with Trunk sensor, 8- direction body tilt and Spine balance 3D) may be beneficial for improving motor recovery, activities of daily living, and balance after stroke when compared to General Postural Training.
- Neurofeedback facilitation with motor imagery may be beneficial for improving functional mobility and balance, but not motor recovery, activities of daily living, and gait speed, after stroke when compared to Sham neurofeedback with motor imagery.
- 3D balance training using visual feedback with Conventional therapy may be beneficial for improving biomechanical gait measures, gait speed, balance, and falls and fear of falling after stroke when compared to Conventional therapy.
- Posturographic platform biofeedback training may be beneficial for improving functional mobility and balance after stroke when compared to hospital treatment.
- Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit) may be beneficial for improving balance, but not biomechanical gait measures, after stroke when compared to Trunk stabilization exercises; the literature is mixed regarding muscle strength.
- Gaming Assisted Visual feedback for balance training with Conventional therapy may be beneficial for improving biomechanical gait measures after stroke when compared to Balance training exercises with Conventional therapy; the literature is mixed regarding biomechanical balance measures, range of motion, and balance.
- Wii Fit balance training may not be beneficial for improving balance after stroke when compared to Tetrax biofeedback balance training.
- Smartphone visual feedback for trunk control training with Conventional care may be beneficial for improving functional mobility and balance after stroke when compared to Conventional care.
- Balance training using Biodex stability system with visual biofeedback may not be beneficial for improving biomechanical balance measures and balance after stroke when compared to Balance training.
- Treadmill training with Rhythmic auditory feedback may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Treadmill training.
- Balance training with postural control visual biofeedback and conventional rehabilitation may be beneficial for improving functional mobility and balance, but not activities of daily living, after stroke when compared to Conventional rehabilitation.

- Space balance 3D training using visual feedback program with Conventional rehabilitation may not be beneficial for improving functional mobility and balance after stroke when compared to Conventional rehabilitation.
- Stepper Exercise with Visual Feedback (with mirror) may be beneficial for improving gait speed, but not functional mobility, after stroke when compared to Stepper Exercise; the literature is mixed regarding muscle strength.
- Botulinum Toxin A injection (under ultrasound guidance) with electromyography biofeedback treatment and conventional care may not be beneficial for improving biomechanical gait measures, spasticity, and gait speed after stroke when compared to Botulinum Toxin A injection (under ultrasound guidance) with conventional care.
- Balance Platform Training with Audio-visual Feedback with Rehabilitation program may not be beneficial for improving biomechanical balance measures, activities of daily living, functional mobility, and balance after stroke when compared to Rehabilitation program with postural training with physiotherapy.
- Balance training with postural control visual biofeedback (SMART Balance master) may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional physical therapy with balance training.
- Balance training with postural control visual biofeedback may be beneficial for improving balance after stroke when compared to Conventional physiotherapy.
- Balance training with self- controlled postural control visual biofeedback may be beneficial for improving biomechanical balance measures after stroke when compared to Balance training with no control over postural control visual biofeedback.
- Balance training with postural control visual biofeedback from unaffected side and physiotherapy may not be beneficial for improving motor recovery, spasticity, functional mobility, and balance after stroke when compared to Stand-up task with physiotherapy.
- 3D balance exercises (3D Thera-Balance) with visual feedback may be beneficial for improving balance, but not gait speed, after stroke when compared to Weight shifting exercises.
- Usual rehabilitation with Sit-to- Stand training and visual feedback may not be beneficial for improving functional mobility after stroke when compared to Usual rehabilitation with Arm task training; the literature is mixed regarding biomechanical balance measures.
- Balance Training with a kinaesthetic ability training (KAT) device (postural control visual biofeedback) may be beneficial for improving biomechanical balance measures, but not motor recovery and activities of daily living, after stroke when compared to Conventional rehabilitation.
- Balance training with force platform biofeedback and Conventional rehabilitation may not be beneficial for improving motor recovery, activities of daily living, and functional mobility after stroke when compared to Conventional rehabilitation.
- Force platform biofeedback balance training with Conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Conventional rehabilitation.
- Balance training with postural control visual biofeedback (SMART Balance master) may not be beneficial for improving biomechanical balance measures, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Conventional rehabilitation.
- Trunk postural control training with visual and auditory feedback with Conventional neurorehabilitation may be beneficial for improving functional mobility and balance, but not muscle strength, spasticity, and activities of daily living, after stroke when compared to Conventional neurorehabilitation.
- Physical therapy with visual biofeedback (SMART Balance master forceplate) may not be beneficial for improving functional mobility and balance after stroke when compared to Physical therapy.
- Balance training with Visual feedback may not be beneficial for improving biomechanical balance measures, gait speed, functional mobility, and balance after stroke when compared to Balance training with Verbal and tactile cues.
- Visual feedback with Nottingham Balance Platform training and physical therapy may be beneficial for improving motor recovery, biomechanical gait measures, biomechanical balance measures, and balance after stroke when compared to Sham visual feedback with Nottingham Balance Platform training and physical therapy.

- Standing practice with Force platform biofeedback may be beneficial for improving biomechanical gait measures after stroke when compared to Standing training table.
- Continuous Auditory Feedback During Sit-to-Stand Training may be beneficial for improving motor recovery, biomechanical balance measures, and functional mobility, but not activities of daily living, after stroke when compared to No Feedback During Sit-to- stand Training.
- Gait training with functional electrical stimulation may be beneficial for improving range of motion after stroke when compared to care; the literature is mixed regarding biomechanical gait measures.
- Visual biofeedback providing posture information may be beneficial for improving biomechanical balance measures after stroke when compared to Standing without biofeedback.
- Pressure sensor-based vibrotactile biofeedback may be beneficial for improving biomechanical balance measures after stroke when compared to Visual biofeedback providing posture information.
- Constant-force EMG- biofeedback Tibalis anterior training with general Physiotherapy may be beneficial for improving muscle strength after stroke when compared to Upper extremity exercise with general Physiotherapy.
- Visual biofeedback training with Conventional rehabilitation may be beneficial for improving biomechanical balance measures after stroke when compared to Conventional rehabilitation.
- Variable-force EMG- biofeedback Tibalis anterior training with general Physiotherapy may be beneficial for improving muscle strength after stroke when compared to Upper extremity exercise with general Physiotherapy.

A.16 Dual-Task Training (Table 16)

Key Points

- Cognitive Dual Motor Task may be beneficial for improving biomechanical gait measures and biomechanical balance measures, but not motor recovery, gait endurance, and balance, after stroke when compared to Conventional Therapy or No Treatment; the literature is mixed regarding gait speed and functional mobility.
- Dual Task may be beneficial for improving gait speed and balance, but not motor recovery, biomechanical gait measures, neurophysiological measures, activities of daily living, gait endurance, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Single Task Training or Control.
- Dual Cognitive-Motor Task may be beneficial for improving functional mobility, but not motor recovery, biomechanical gait measures, activities of daily living, and balance, after stroke when compared to Balance Training; the literature is mixed regarding biomechanical balance measures and gait speed.
- Dual-Task and Resistance Exercise may not be beneficial for improving muscle strength, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Aerobic and Resistance Exercise.
- Dual-task training with variable priority instructional sets may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Dual-task training with fixed priority instructional sets.
- Motor dual task training with Conventional care may be beneficial for improving functional mobility, but not balance, after stroke when compared to Cognitive dual task training with Conventional care or Motor imagery and Conventional care.
- Dual-Task Training may be beneficial for improving functional mobility and balance after stroke when compared to Vestibular Rehabilitation.
- Cognitive Task may not be beneficial for improving biomechanical gait measures and gait endurance after stroke when compared to Motor Task or No Task in Various Settings.
- Cognitive Therapeutic Exercise Combined with Goal-Directed Training may be beneficial for improving functional mobility, balance, and falls and fear of falling after stroke when compared to Goal-Directed Training Alone.
- Cognitive Training may be beneficial for improving biomechanical gait measures, but not gait speed, after stroke when compared to Conventional Therapy.

- Dual-Task Training with Motor Imagery may be beneficial for improving functional mobility and balance after stroke when compared to Dual-Task Training Alone.
- High-intensity multiplanar trunk training with dual-task training and conventional rehabilitation may be beneficial for improving gait speed, functional mobility, balance, and quality of life after stroke when compared to Trunk training with conventional rehabilitation.
- Aquatic-based Dual-task Motor Training may be beneficial for improving biomechanical gait measures, biomechanical balance measures, and gait speed after stroke when compared to Land-based Dual-task Motor Training.
- Aquatic therapy (Dual-task training with upper extremity tasks) may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to Neurodevelopmental techniques.

A.17 Mental Practice (Table 17)

Key Points

- Gait Training with Motor Imagery or Mental Practice may be beneficial for improving motor recovery, gait speed, functional mobility, and balance after stroke when compared to Gait Training.
- Task-Specific Training with Mental Practice may be beneficial for improving muscle strength and gait speed after stroke when compared to Task-Specific Training.
- Task-Specific Training with Mental Practice may be beneficial for improving biomechanical balance measures, gait endurance, and functional mobility, but not motor recovery, biomechanical gait measures, and gait speed, after stroke when compared to Conventional Training or No Treatment.
- Proprioception Training with Motor Imagery may be beneficial for improving biomechanical balance measures, sensory and proprioceptive function, and balance, but not functional mobility, after stroke when compared to Proprioception Training.
- Action Observation may not be beneficial for improving biomechanical gait measures, functional mobility, and balance after stroke when compared to Motor Imagery or Conventional Therapy; the literature is mixed regarding gait speed.
- Neurofeedback Facilitation with Motor Imagery may be beneficial for improving functional mobility, but not motor recovery, activities of daily living, and gait speed, after stroke when compared to Sham; the literature is mixed regarding balance.
- Mental Practice may be beneficial for improving gait speed, but not motor recovery and activities of daily living, after stroke when compared to Muscle Relaxation.
- Circuit Training with Mental Practice may be beneficial for improving functional mobility, but not biomechanical gait measures, muscle strength, gait speed, and gait endurance, after stroke when compared to Circuit Training with Education.
- Visual Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training.
- Visual Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Visual Locomotor Training with Auditory Step Rhythm.
- Visual Locomotor Imagery Training may result in lesser improvements in neurophysiological measures and functional mobility when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.
- Kinesthetic Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Visual Locomotor Training with Auditory Step Rhythm.
- Kinesthetic Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.
- Visual Locomotor Training with Auditory Step Rhythm may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.
- Mental Imagery may be beneficial for improving balance and quality of life, but not motor recovery, biomechanical gait measures, muscle strength, activities of daily living, functional mobility, and falls and

fear of falling, after stroke when compared to Conventional Training or Sham; the literature is mixed regarding gait speed.

- Body Awareness Therapy may not be beneficial for improving gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Continuing Usual Daily Activities.
- Motor dual task training with Conventional care may be beneficial for improving functional mobility, but not balance, after stroke when compared to Cognitive dual task training with Conventional care or Motor imagery and Conventional care.
- Cognitive Sensory Motor Training may be beneficial for improving biomechanical balance measures, muscle strength, gait speed, and balance after stroke when compared to Conventional Therapy.
- Mental Practice may not be beneficial for improving muscle strength, gait speed, functional mobility, and quality of life after stroke when compared to Cognitive Training.
- Motor Imagery with Virtual Reality may be beneficial for improving motor recovery, gait speed, functional mobility, and balance after stroke when compared to Virtual Reality Alone.
- Dual-task training with motor imagery may be beneficial for improving functional mobility and balance after stroke when compared to Dual-task training.
- Modified sit-to-stand training with mental practice with conventional therapy may be beneficial for improving functional mobility and balance after stroke when compared to Conventional Treatment.
- Task-oriented circuit class training with Motor imagery may be beneficial for improving gait endurance and functional mobility, but not biomechanical gait measures, after stroke when compared to rehabilitation (Bobath); the literature is mixed regarding gait speed.

A.18 Action Observation (Table 18)

Key Points

- Backward Walking Action Observation may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility, and falls and fear of falling after stroke when compared to Sham or Conventional therapy.
- Action Observation Physical Training may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and functional mobility after stroke when compared to Sham Action Observation Training.
- Functional Action Observation may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to General Action Observation.
- Action Observation Training with Gait Training may be beneficial for improving biomechanical balance measures, gait speed, and falls and fear of falling, but not biomechanical gait measures, functional mobility, and balance, after stroke when compared to Gait Training.
- Action Observation with Treadmill Training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Treadmill Training.
- Action Observation with functional electrical stimulation and Gait Training may be beneficial for improving biomechanical balance measures and gait speed, but not neurophysiological measures and balance, after stroke when compared to Gait Training and functional electrical stimulation.
- Action observation training with Rhythmic auditory stimulation and physical therapy may be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Action observation with physical therapy.

A.19 Mirror Therapy (Table 19)

Key Points

- Mirror Therapy may be beneficial for improving motor recovery, biomechanical gait measures, biomechanical balance measures, range of motion, neurophysiological measures, activities of daily living,

gait endurance, functional mobility, and balance, but not muscle strength, spasticity, gait speed, and quality of life, after stroke when compared to Conventional Therapy or Sham Therapy.

- Treadmill Training Combined with Mirror Therapy may not be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Treadmill Training.
- Mirror Therapy with Task Oriented Training may be beneficial for improving biomechanical balance measures, gait speed, and balance after stroke when compared to Task Oriented Training; the literature is mixed regarding muscle strength and functional mobility.
- Mirror therapy may not be beneficial for improving motor recovery, sensory and proprioceptive function, and gait speed after stroke when compared to Mirror therapy with Mesh glove (afferent stimulation); the literature is mixed regarding spasticity; Mirror therapy may result in lesser improvements in activities of daily living when compared to Mirror therapy with Mesh glove (afferent stimulation).
- Mirror Therapy with Stimulation may not be beneficial for improving motor recovery, spasticity, sensory and proprioceptive function, and activities of daily living after stroke when compared to Mirror Therapy or Task Oriented Training; the literature is mixed regarding biomechanical gait measures, range of motion, and gait speed.
- Mirror Therapy combined with neuromuscular electrical stimulation may be beneficial for improving muscle strength, gait speed, and balance, but not motor recovery, spasticity, range of motion, gait endurance, and functional mobility, after stroke when compared to Mirror Therapy with Sham neuromuscular electrical stimulation or Conventional Therapy.
- Mirror Therapy combined with functional electrical stimulation may be beneficial for improving motor recovery, biomechanical gait measures, range of motion, gait speed, balance, and falls and fear of falling after stroke when compared to Conventional Therapy.
- Mirror Therapy with repetitive transcranial magnetic stimulation may be beneficial for improving biomechanical balance measures, but not functional mobility and balance, after stroke when compared to Mirror Therapy with Sham Stimulation.
- Mirror Therapy with Virtual Reality may be beneficial for improving motor recovery and range of motion, but not spasticity and activities of daily living, after stroke when compared to Conventional therapy; the literature is mixed regarding balance.
- Mirror Therapy with Verbal Feedback may be beneficial for improving balance after stroke when compared to Mirror Therapy Alone.
- At home Mirror therapy + Usual care may not be beneficial for improving muscle strength, spasticity, sensory and proprioceptive function, functional mobility, and balance after stroke when compared to At home Lower limb exercises + Usual care.
- Treadmill Training with Mirror Therapy may not be beneficial for improving motor recovery, spasticity, gait speed, and gait endurance after stroke when compared to Treadmill Training with Sham.
- Home based Isometric Unilateral Strength Training with Mirror Therapy may not be beneficial for improving muscle strength, spasticity, gait speed, functional mobility, and quality of life after stroke when compared to Home based Isometric Unilateral Strength Training.
- Electrical stimulation with mirror therapy may be beneficial for improving muscle strength, gait speed, and balance, but not biomechanical gait measures and spasticity, after stroke when compared to Sham electrical stimulation with sham mirror therapy.
- Home rehabilitation, then Clinic rehabilitation may be beneficial for improving functional mobility, but not activities of daily living and gait speed, after stroke when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice; the literature is mixed regarding quality of life.
- Low frequency (1Hz) Repetitive Transcranial Magnetic Stimulation with mirror therapy may be beneficial for improving biomechanical balance measures, gait endurance, and functional mobility after stroke when compared to Sham repetitive transcranial magnetic stimulation with mirror therapy.
- Mirror therapy with Functional electrical stimulation may be beneficial for improving motor recovery, range of motion, and gait speed after stroke when compared to Conventional therapy.
- Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy may be beneficial for improving muscle strength and balance, but not spasticity, gait endurance, and functional mobility, after stroke when compared to Conventional therapy.

- Mirror therapy may not be beneficial for improving motor recovery, spasticity, sensory and proprioceptive function, and gait speed after stroke when compared to Mirror therapy with Sham mesh glove; Mirror therapy may result in lesser improvements in activities of daily living when compared to Mirror therapy with Sham mesh glove.
- Mirror therapy with Mesh glove (afferent stimulation) may not be beneficial for improving motor recovery, sensory and proprioceptive function, activities of daily living, and gait speed after stroke when compared to Mirror therapy with Sham mesh glove; the literature is mixed regarding spasticity.
- Mirror Therapy with Conventional care may result in lesser improvements in gait speed when compared to Task-oriented training with Conventional care; the literature is mixed regarding biomechanical gait measures.

A.20 Aquatic Therapy (Table 20)

Key Points

- Aquatic Therapy may be beneficial for improving motor recovery, neurophysiological measures, sensory and proprioceptive function, and activities of daily living, but not biomechanical balance measures, muscle strength, pain, gait speed, functional mobility, and balance, after stroke when compared to Conventional Therapy; the literature is mixed regarding biomechanical gait measures and gait endurance.
- Aquatic Therapy may be beneficial for improving aerobic measures and gait speed, but not balance, after stroke when compared to Land-Based Upper Extremity Exercises; the literature is mixed regarding muscle strength.
- Aquatic Treadmill Walking or Aerobic Therapy may not be beneficial for improving motor recovery, biomechanical gait measures, biomechanical balance measures, spasticity, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Overground or Treadmill Walking or Cycle Ergometer; the literature is mixed regarding muscle strength, range of motion, and neurophysiological measures.
- Aquatic Ai Chi Therapy with Dry Land Therapy may not be beneficial for improving pain after stroke when compared to Aquatic Ai Chi Therapy; the literature is mixed regarding biomechanical gait measures and functional mobility; Aquatic Ai Chi Therapy with Dry Land Therapy may result in lesser improvements in balance when compared to Aquatic Ai Chi Therapy.
- Dual-Task Aquatic Training may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, functional mobility, and balance after stroke when compared to Neurodevelopmental Techniques or Land-Based Dual Motor Task.
- Aquatic Therapy with Strength Training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Aquatic Therapy.
- Sequential Preparatory Approach Aquatic Therapy may be beneficial for improving spasticity, balance, and quality of life, but not activities of daily living and functional mobility, after stroke when compared to Aquatic Therapy.
- Anti gravity treadmill may be beneficial for improving aerobic measures and gait endurance, but not activities of daily living and balance, after stroke when compared to Conventional therapy.
- Land-based and aquatic trunk exercises with conventional physiotherapy may be beneficial for improving activities of daily living and balance after stroke when compared to Conventional physiotherapy or 60min/d, 5d/wk, 4wks conventional physiotherapy.
- Aquatic Ai Chi therapy with Dry land therapy may be beneficial for improving functional mobility and pain, but not balance, after stroke when compared to Training on dry land.
- Aquatic Ai Chi therapy may be beneficial for improving balance and pain, but not functional mobility, after stroke when compared to Training on dry land.
- Waterjet resistance aquatic treadmill training with conventional PT may be beneficial for improving biomechanical gait measures, gait speed, and balance after stroke when compared to Ankle weight aquatic treadmill training with conventional PT.

A.21 Strength and Resistance Training (Table 21)

Key Points

- Strength or Resistance Training may be beneficial for improving biomechanical gait measures, muscle strength, aerobic measures, gait speed, functional mobility, and balance, but not spasticity, neurophysiological measures, pain, activities of daily living, gait endurance, and quality of life, after stroke when compared to Conventional Therapy or Educational Classes; the literature is mixed regarding motor recovery, biomechanical balance measures, and range of motion.
- Lower limb resistance training with Abdominal draw-in maneuver (abdominal drawing-in maneuver) and Conventional tailored physical therapy may be beneficial for improving activities of daily living and balance after stroke when compared to lower limb exercise with abdominal drawing-in maneuver and Conventional tailored physical therapy.
- Task oriented circuit gait training may be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Strength training of lower extremities.
- Functional strength training - upper limb may not be beneficial for improving functional mobility after stroke when compared to Functional strength training - lower limb.
- Rehabilitation program with leg training may not be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Rehabilitation program with Arm training.
- Strength or Resistance Training may be beneficial for improving muscle strength, aerobic measures, and gait endurance, but not activities of daily living, gait speed, functional mobility, and quality of life, after stroke when compared to Stretching or Relaxation; the literature is mixed regarding balance.
- Aerobic and Resistance Training may be beneficial for improving spasticity, activities of daily living, gait speed, and quality of life, but not muscle strength, range of motion, neurophysiological measures, aerobic measures, gait endurance, functional mobility, and balance, after stroke when compared to Conventional Therapy or Aerobic Training.
- Aerobic training may be beneficial for improving aerobic measures, but not gait speed, gait endurance, and quality of life, after stroke when compared to Progressive resistance training; Aerobic training may result in lesser improvements in muscle strength when compared to Progressive resistance training.
- Sham progressive resistance training with Cycling may be beneficial for improving gait endurance after stroke when compared to Sham progressive resistance training with Sham cycling.
- Strength and Resistance Training Modalities may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, quality of life, and motor recovery, but not functional mobility, after stroke when compared to Limb overloading resistance training; the literature is mixed regarding muscle strength.
- Eccentric resistance training with Gait training may result in lesser improvements in muscle strength and gait speed when compared to Concentric resistance training with Gait training.
- Strength and Resistance Training Intensity may not be beneficial for improving biomechanical gait measures, activities of daily living, gait speed, gait endurance, and functional mobility after stroke when compared to High intensity resistance training (HIRT).
- Low intensity walking and resistance training program may be beneficial for improving gait endurance and quality of life, but not muscle strength, gait speed, functional mobility, and balance, after stroke when compared to High intensity walking and resistance training program.
- Home based Isometric Unilateral Strength Training with Mirror Therapy may not be beneficial for improving muscle strength, spasticity, gait speed, functional mobility, and quality of life after stroke when compared to Home based Isometric Unilateral Strength Training.
- Strength Training with Visual Feedback may be beneficial for improving motor recovery and muscle strength, but not gait speed and balance, after stroke when compared to Physical Therapy; the literature is mixed regarding sensory and proprioceptive function.
- Resistance Training with Balance Training may be beneficial for improving gait speed and gait endurance, but not motor recovery, neurophysiological measures, activities of daily living, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy; the literature is mixed regarding balance.

- Resistance Training with and without repetitive transcranial magnetic stimulation may be beneficial for improving neurophysiological measures and gait speed after stroke when compared to Resistance Training or repetitive transcranial magnetic stimulation Alone.
- Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation may be beneficial for improving muscle strength, neurophysiological measures, and gait speed after stroke when compared to Ankle Strengthening.
- Dietary Supplements with Resistance training may be beneficial for improving muscle strength, but not neurophysiological measures, after stroke when compared to Resistance Training Alone; the literature is mixed regarding activities of daily living.
- Muscle Strength Training to Paralytic Muscles may not be beneficial for improving neurophysiological measures, gait speed, and functional mobility after stroke when compared to Muscle Strength Training to Non-paralytic Muscles.
- Strength Training with Neurodevelopmental Techniques may be beneficial for improving biomechanical gait measures after stroke when compared to Neurodevelopmental Techniques Alone.
- Resistance-based, reciprocal, affected leg locomotor training protocol using the NuStep apparatus may not be beneficial for improving motor recovery and balance after stroke when compared to Home exercise program.
- Core strengthening exercises with Conventional rehab may be beneficial for improving functional mobility and balance after stroke when compared to Conventional rehab.
- Metronome training with core strengthening and general balance exercises may be beneficial for improving functional mobility after stroke when compared to Core strengthening with general balance exercises.
- 120g Nutritional supplement (Reha-Time Jelly BCAA enriched nutritional supplement) with resistance exercise training program may not be beneficial for improving muscle strength, neurophysiological measures, aerobic measures, activities of daily living, gait speed, and gait endurance after stroke when compared to Resistance training exercise program.
- Acupuncture with trunk strengthening training and conventional rehab may be beneficial for improving biomechanical gait measures, gait speed, functional mobility, and balance after stroke when compared to Conventional rehab with trunk strengthening training.
- Individualized cardio rehabilitation (aerobic & resistance training) with Conventional stroke rehab may not be beneficial for improving aerobic measures, functional mobility, and balance after stroke when compared to Conventional Stroke Rehabilitation.
- Circuit walking, balance, cycling and strength training (CBCS) may be beneficial for improving motor recovery, gait endurance, balance, and quality of life, but not gait speed, after stroke when compared to Sociocultural intervention (board games, cultural discourse and drama).
- The literature is mixed regarding the effect of Extracorpeal shockwave therapy on spasticity and neurophysiological measures after stroke when compared to conventional rehab.
- Extracorpeal shockwave therapy may be beneficial for improving spasticity after stroke when compared to extracorporeal shockwave therapy with Isokinetic strength training; the literature is mixed regarding neurophysiological measures.
- The literature is mixed regarding the effect of Foot Mobilization with Intrinsic Foor Muscles Facilitation and (Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations) on biomechanical balance measures after stroke when compared to Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations.
- Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training) may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, balance, and falls and fear of falling after stroke when compared to Sham taping with exercise training.
- Dual Task (Consisting aerobic and resistance exercises while performing cognitive task) may not be beneficial for improving muscle strength, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Aerobic and Resistance Exercises, without Performing Cognitive Task.

- Aquatic training with under water strength training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Aquatic training.
- Early conventional physical therapy with intensive strength exercises may be beneficial for improving motor recovery, but not activities of daily living and balance, after stroke when compared to Conventional physiotherapy.
- Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training may not be beneficial for improving gait speed, gait endurance, functional mobility, and quality of life after stroke when compared to Sham Combined aerobic and resistance training with Sham Cognitive training.
- Ankle strengthening training with brain-computer interface-based functional electrical stimulation on TA may be beneficial for improving gait speed, but not biomechanical gait measures and balance, after stroke when compared to Ankle strengthening training with functional electrical stimulation on TA.
- Leucine enriched amino acid with resistant training may be beneficial for improving muscle strength, but not neurophysiological measures, after stroke when compared to Resistant training; the literature is mixed regarding activities of daily living.
- Task oriented circuit gait training may be beneficial for improving gait speed, functional mobility, balance, and gait endurance after stroke when compared to Educational session on stroke management.
- Aerobic training on cycle ergometer may not be beneficial for improving muscle strength, aerobic measures, gait speed, gait endurance, and balance after stroke when compared to Sham training of upper extremities.
- Aerobic training (over ground walking) with Resistance training may not be beneficial for improving range of motion, neurophysiological measures, aerobic measures, gait endurance, and functional mobility after stroke when compared to Aerobic Training.
- Aerobic Training (fast walking and walking up-stairs) with Resistance Training may be beneficial for improving gait speed, gait endurance, and functional mobility, but not balance, after stroke when compared to Conventional care; the literature is mixed regarding aerobic measures.
- Task Oriented circuit LE strength training with physiotherapy may be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Conventional physiotherapy.
- Aerobic cycling with progressive resistance training (PRT) may be beneficial for improving muscle strength after stroke when compared to Sham cycling with Sham PRT; the literature is mixed regarding gait speed, aerobic measures, gait endurance, quality of life, and functional mobility.
- Task-oriented progressive resistance strength training may be beneficial for improving biomechanical gait measures, muscle strength, gait speed, gait endurance, and functional mobility after stroke when compared to No treatment.
- Strength training of lower extremities may be beneficial for improving gait endurance after stroke when compared to Educational session on stroke management.
- Rehabilitation program with leg training may be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Rehabilitation program with arm & leg immobilized.
- Rehabilitation program with Arm training may not be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Rehabilitation program with arm & leg immobilized.
- Progressive resistance training may not be beneficial for improving muscle strength, aerobic measures, gait speed, gait endurance, and quality of life after stroke when compared to Resistance training of the arms (sham).
- Aerobic training may be beneficial for improving aerobic measures, but not gait speed, gait endurance, and quality of life, after stroke when compared to Resistance training of the arms (sham).
- Progressive resistive training with Open-kinetic chain may not be beneficial for improving biomechanical gait measures after stroke when compared to No training.
- The literature is mixed regarding the effect of Progressive resistive training with closed-kinetic chain on biomechanical gait measures after stroke when compared to Progressive resistive training with Open-kinetic chain or No training.

A.22 Rhythmic Auditory Stimulation (Table 22)

Key Points

- Treadmill Training with Rhythmic Auditory Stimulation may be beneficial for improving gait endurance, functional mobility, and balance, but not biomechanical balance measures, after stroke when compared to Treadmill Training; the literature is mixed regarding biomechanical gait measures and gait speed.
- Overground Gait Training with Rhythmic Auditory Stimulation may be beneficial for improving biomechanical balance measures, neurophysiological measures, gait speed, and quality of life, but not motor recovery, activities of daily living, gait endurance, functional mobility, and balance, after stroke when compared to Overground Gait Training; the literature is mixed regarding biomechanical gait measures.
- Physical Therapy with Rhythmic Auditory Feedback may not be beneficial for improving motor recovery, activities of daily living, gait endurance, functional mobility, and quality of life after stroke when compared to Physical Therapy or Conventional Therapy; the literature is mixed regarding range of motion.
- Treadmill Training with Rhythmic Auditory Stimulation may be beneficial for improving gait speed, gait endurance, and functional mobility after stroke when compared to Overground Gait with Rhythmic Auditory Stimulation; the literature is mixed regarding biomechanical gait measures.
- Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may be beneficial for improving motor recovery and muscle strength, but not activities of daily living, gait speed, functional mobility, and balance, after stroke when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.
- Auditory Stimulation with Robot Training may be beneficial for improving motor recovery and gait speed, but not activities of daily living, after stroke when compared to Virtual Reality with Robot Training or Conventional Training.
- Visual Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training.
- Visual Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Visual Locomotor Training with Auditory Step Rhythm.
- Kinesthetic Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.
- Kinesthetic Locomotor Imagery Training may not be beneficial for improving functional mobility after stroke when compared to Visual Locomotor Training with Auditory Step Rhythm.
- Visual Locomotor Training with Auditory Step Rhythm may not be beneficial for improving functional mobility after stroke when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.
- Action observation training with Rhythmic auditory stimulation and physical therapy may be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Action observation with physical therapy.
- Music-movement therapy (MMT) may not be beneficial for improving muscle strength and range of motion after stroke when compared to Conventional care.
- Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- Auditory stimulation with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- Inclined treadmill training may be beneficial for improving gait speed, gait endurance, functional mobility, and balance after stroke when compared to Treadmill training; the literature is mixed regarding biomechanical gait measures.
- Inclined treadmill training with Rhythmic auditory stimulation may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Inclined treadmill training.

- Rhythmic auditory stimulation with conventional treatment may not be beneficial for improving motor recovery after stroke when compared to Visual cueing with conventional treatment; Rhythmic auditory stimulation with conventional treatment may result in lesser improvements in functional mobility when compared to Visual cueing with conventional treatment.
- Rhythmic auditory stimulation with conventional treatment may be beneficial for improving motor recovery and functional mobility after stroke when compared to Conventional treatment.
- Visual cueing with conventional treatment may be beneficial for improving motor recovery and functional mobility after stroke when compared to Conventional treatment.
- Visual Locomotor Imagery Training may result in lesser improvements in neurophysiological measures and functional mobility when compared to Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm.

A.23 Respiratory Training and Devices (Table 23)

Key Points

- 4 week inspiratory muscle training may not be beneficial for improving activities of daily living after stroke when compared to 8 week inspiratory muscle training; 4 week inspiratory muscle training may result in lesser improvements in aerobic measures and gait endurance when compared to 8 week inspiratory muscle training.
- Respiratory Muscle Training may be beneficial for improving aerobic measures and gait endurance, but not motor recovery, activities of daily living, functional mobility, balance, and quality of life, after stroke when compared to Conventional Rehabilitation or Sham Respiratory Muscle Training; the literature is mixed regarding muscle strength.
- Respiratory Training may be beneficial for improving activities of daily living and balance, but not aerobic measures, after stroke when compared to Conventional Rehabilitation with Liuzijue Qigong.
- Continuous Positive Airway Pressure may not be beneficial for improving activities of daily living, gait endurance, and balance after stroke when compared to Conventional Rehabilitation.
- Respiratory Muscle Training may be beneficial for improving aerobic measures, but not gait endurance, after stroke when compared to Cycle Ergometer Training.
- Inspiratory muscle training (IMT) may be beneficial for improving aerobic measures and functional mobility, but not pain, after stroke when compared to Conventional rehabilitation; the literature is mixed regarding activities of daily living.
- Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT) may be beneficial for improving pain, but not aerobic measures, activities of daily living, and functional mobility, after stroke when compared to Conventional rehabilitation.
- Inspiratory muscle training (IMT) may be beneficial for improving aerobic measures after stroke when compared to Breathing retraining, diaphragmatic breathing and pursed-lips breathing (BRT).

A.24 Home-Based and Caregiver-Mediated Exercise Programs (Table 24)

Key Points

- Home-Based Physiotherapy and Exercise Programs may be beneficial for improving motor recovery, but not biomechanical gait measures, muscle strength, neurophysiological measures, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy or No Therapy; the literature is mixed regarding spasticity.
- Home rehabilitation, then Clinic rehabilitation may be beneficial for improving functional mobility, but not activities of daily living and gait speed, after stroke when compared to Clinic rehabilitation, then home rehabilitation. Both settings involved mirror therapy and functional task practice; the literature is mixed regarding quality of life.

- Home-based Oculomotor/Gaze Stability Exercises may be beneficial for improving functional mobility, but not falls and fear of falling, after stroke when compared to Conventional Rehabilitation.
- Caregiver-Mediated Programs may be beneficial for improving motor recovery, spasticity, activities of daily living, gait endurance, balance, and quality of life, but not gait speed and functional mobility, after stroke when compared to Conventional Care.
- Nursing Mediated Program may be beneficial for improving motor recovery, spasticity, activities of daily living, gait speed, and quality of life, but not muscle strength and functional mobility, after stroke when compared to Conventional Care.
- Home-based cycle ergometer exercise may not be beneficial for improving gait speed, gait endurance, balance, and quality of life after stroke when compared to Home-based overground walking exercise.
- Early Discharged At-Home Supported Training may not be beneficial for improving gait speed and balance after stroke when compared to Conventional Post-Discharge Rehabilitation.
- Outpatient Clinic Care Follow-up may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional Control.
- Specialist Community Rehabilitation may not be beneficial for improving muscle strength, activities of daily living, and quality of life after stroke when compared to Conventional Rehabilitation.
- Rapid rehabilitation nursing with continuous nursing after discharge may be beneficial for improving activities of daily living, functional mobility, and quality of life after stroke when compared to Routine nursing.
- Programmed Nursing Intervention (Including health education, personalized functional exercise plans, restoration function training) may be beneficial for improving motor recovery, activities of daily living, and quality of life after stroke when compared to routine rehabilitation training.
- Home based physical activity and walking training program may not be beneficial for improving activities of daily living, functional mobility, and quality of life after stroke when compared to Conventional care.
- Augmented reality with home based exercise program may be beneficial for improving falls and fear of falling, but not balance and quality of life, after stroke when compared to Home based exercise program; the literature is mixed regarding functional mobility.
- Active dual-hemispheric transcranial direct current stimulation with Home-based exercise may not be beneficial for improving motor recovery, muscle strength, gait endurance, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with Home-based exercise.
- Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care may be beneficial for improving gait endurance, functional mobility, and balance, but not aerobic measures and activities of daily living, after stroke when compared to Physical Activity with Usual physiotherapy.
- BASNEF model motivational training with home-based rehabilitation may be beneficial for improving motor recovery after stroke when compared to Conventional Care.
- Home-based isometric unilateral strength training with mirror therapy may not be beneficial for improving muscle strength, spasticity, gait speed, functional mobility, and quality of life after stroke when compared to Home-based isometric unilateral strength training.
- Caregiver-mediated exercise program with e-health support with telerehabilitation may not be beneficial for improving motor recovery, muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Conventional therapy.
- Nurse-organized, family caregiver delivered rehabilitation (supported by a custom- designed smartphone application) may not be beneficial for improving activities of daily living and quality of life after stroke when compared to Usual care; the literature is mixed regarding functional mobility.
- Caregiver-mediated iPad exercise program with FitBit activity monitor (real-time feedback) may not be beneficial for improving motor recovery, muscle strength, activities of daily living, functional mobility, balance, and quality of life after stroke when compared to Usual care.
- Custom Occupational therapy with Caregiver training workshop may not be beneficial for improving activities of daily living, functional mobility, and quality of life after stroke when compared to Usual care alone.
- Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may be beneficial for improving gait speed, but not spasticity, gait endurance, and functional mobility, after stroke when compared to Botulinum Toxin A Injection.

A.25 Telerehabilitation and Technology-Based Home Exercise Programs (Table 25)

Key Points

- Home Based Therapy Using Technology and Telerehabilitation may be beneficial for improving motor recovery, biomechanical gait measures, spasticity, neurophysiological measures, and gait endurance, but not muscle strength, range of motion, pain, activities of daily living, gait speed, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy or No Therapy.
- Telerehabilitation Computerized Complex Repetitive Ankle Movement Training may not be beneficial for improving biomechanical gait measures, neurophysiological measures, and gait speed after stroke when compared to Simple Ankle Movement Training.
- Telerehabilitation Physiotherapy Combined with electromyography-neuromuscular electrical stimulation may be beneficial for improving motor recovery, but not activities of daily living, balance, and quality of life, after stroke when compared to Conventional Therapy Combined with electromyography-neuromuscular electrical stimulation.
- Caregiver-Mediated Programs using Telerehabilitation or Technology may not be beneficial for improving muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Conventional Care; the literature is mixed regarding motor recovery.
- Video-Based Home Exercise Training may be beneficial for improving activities of daily living after stroke when compared to Paper-Based Home Exercise Training; the literature is mixed regarding falls and fear of falling.
- Home based Multimodal rehabilitation program by mHealth app may be beneficial for improving activities of daily living, gait speed, gait endurance, and quality of life, but not functional mobility, after stroke when compared to Conventional care.
- Smart-watch feedback on daily activity level may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to local routine treatment.
- Virtual reality-based telerehabilitation in Home with conventional physical therapy may not be beneficial for improving functional mobility and balance after stroke when compared to Virtual reality-based rehabilitation in clinic with conventional physical therapy.

A.26 Virtual Reality (Table 26)

Key Points

- Virtual Reality may be beneficial for improving sensory and proprioceptive function, gait speed, and functional mobility, but not motor recovery, biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, neurophysiological measures, pain, activities of daily living, gait endurance, balance, falls and fear of falling, and quality of life, after stroke when compared to Conventional Therapy or No Treatment; the literature is mixed regarding range of motion.
- Game-based constraint-induced movement therapy with Traditional physical therapy may be beneficial for improving biomechanical gait measures and biomechanical balance measures, but not gait speed, functional mobility, and balance, after stroke when compared to General game-based training with Traditional physical therapy.
- Virtual Reality may be beneficial for improving activities of daily living and functional mobility, but not gait speed, balance, and falls and fear of falling, after stroke when compared to Balance Training.
- Virtual Reality Exercise Program may be beneficial for improving falls and fear of falling, but not motor recovery, biomechanical gait measures, functional mobility, balance, and quality of life, after stroke when compared to Exercise Program; the literature is mixed regarding gait speed.
- Virtual Reality Training may not be beneficial for improving biomechanical gait measures after stroke when compared to Treadmill Training; the literature is mixed regarding biomechanical balance measures.

- Virtual Reality with Treadmill Training may be beneficial for improving gait speed, balance, and falls and fear of falling, but not biomechanical gait measures, biomechanical balance measures, gait endurance, functional mobility, and quality of life, after stroke when compared to Conventional Therapy or Treadmill Training.
- Virtual reality treadmill training-based community ambulation may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, functional mobility, and falls and fear of falling after stroke when compared to Community ambulation training.
- Treadmill with optic flow with conventional physical therapy may be beneficial for improving gait speed, gait endurance, and functional mobility, but not balance, after stroke when compared to Treadmill with conventional physical therapy.
- Virtual Reality with Treadmill Training may be beneficial for improving gait speed, but not motor recovery, biomechanical gait measures, biomechanical balance measures, activities of daily living, gait endurance, and functional mobility, after stroke when compared to Overground Gait Training.
- Virtual Reality Robotic Training may be beneficial for improving neurophysiological measures, but not biomechanical gait measures, muscle strength, spasticity, activities of daily living, gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, after stroke when compared to Robotic Training and Conventional Therapy.
- Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may be beneficial for improving muscle strength, but not activities of daily living, functional mobility, and balance, after stroke when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy; the literature is mixed regarding gait speed.
- Virtual Reality Robotic Training may be beneficial for improving gait speed, but not activities of daily living, after stroke when compared to Robotic Training, Auditory Stimulation, and Conventional Therapy.
- Virtual Reality with Other Modalities may be beneficial for improving biomechanical gait measures, spasticity, and gait speed, but not aerobic measures, activities of daily living, and falls and fear of falling, after stroke when compared to Task-specific training; the literature is mixed regarding biomechanical balance measures, gait endurance, functional mobility, and balance.
- Task-oriented training with Virtual reality training may be beneficial for improving motor recovery and balance after stroke when compared to Task-oriented training; the literature is mixed regarding functional mobility.
- Virtual reality therapy and mirror therapy (MT) exercises may be beneficial for improving motor recovery and range of motion, but not spasticity and activities of daily living, after stroke when compared to lower extremity rehabilitation; the literature is mixed regarding balance.
- One session daily high intensity Videogame exercises with medical massage may result in lesser improvements in aerobic measures when compared to two sessions daily high intensity Videogame exercises with medical massage; the literature is mixed regarding biomechanical balance measures.
- Virtual Reality may not be beneficial for improving motor recovery, sensory and proprioceptive function, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Virtual Reality (Nintendo Wii) may not be beneficial for improving motor recovery after stroke when compared to Virtual Reality with Proprioceptive Neuromuscular Facilitation.
- Treadmill training with Virtual reality and Ankle robotics may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, range of motion, and gait speed after stroke when compared to Seated training with Virtual reality and Ankle robotics.
- Brain-Computer Interface Controlled Training may be beneficial for improving motor recovery, but not neurophysiological measures, activities of daily living, functional mobility, and balance, after stroke when compared to Sham.
- Virtual Reality Training may be beneficial for improving activities of daily living and functional mobility after stroke when compared to Strength and Resistance Training; the literature is mixed regarding balance.
- Adaptive foot switch Videogame with Regular physiotherapy may be beneficial for improving biomechanical balance measures after stroke when compared to Regular physiotherapy.
- Wii Balance Intervention may not be beneficial for improving functional mobility, balance, and falls and fear of falling after stroke when compared to Conventional Balance Intervention.

- Group Video game therapy may not be beneficial for improving gait speed after stroke when compared to Conventional care.
- Peripheral nerve mobilization with virtual reality-based gait training may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Conventional exercises.
- Motor imagery with virtual reality training may be beneficial for improving motor recovery, gait speed, functional mobility, and balance after stroke when compared to virtual reality training with Conventional therapy.
- Repetitive transcranial magnetic stimulation with Augmented reality gait adaptive training may be beneficial for improving motor recovery, gait speed, and balance, but not biomechanical gait measures, muscle strength, and neurophysiological measures, after stroke when compared to Augmented reality gait adaptive training.
- Selfpaced treadmill walking in virtual reality environment may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Self Placed Overground Platform walking.
- Lokomat endurance video games may not be beneficial for improving biomechanical gait measures after stroke when compared to Conventional Physiotherapy; the literature is mixed regarding gait speed, gait endurance, biomechanical balance measures, and balance.
- Xbox training during anodal tDCS stimulation to cerebellum may be beneficial for improving gait speed, functional mobility, and balance, but not gait endurance and falls and fear of falling, after stroke when compared to Sham tDCS with xbox training.
- Xbox training during anodal tDCS stimulation to cerebellum may not be beneficial for improving gait speed, gait endurance, functional mobility, and falls and fear of falling after stroke when compared to Xbox training during nodal tDCS stimulation to motor cortex; Xbox training during anodal tDCS stimulation to cerebellum may result in lesser improvements in balance when compared to Xbox training during nodal tDCS stimulation to motor cortex.
- Self paced treadmill walking in virtual reality environment may be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Fixed speed treadmill walking in virtual reality environment.
- Telerehabilitation video games may not be beneficial for improving range of motion, pain, activities of daily living, balance, and quality of life after stroke when compared to Conventional rehab.
- Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy may be beneficial for improving muscle strength, gait speed, functional mobility, balance, and quality of life after stroke when compared to Sit-to-stand Training with physiotherapy.
- Treadmill-based with augmented reality may not be beneficial for improving activities of daily living, gait speed, and functional mobility after stroke when compared to Overground walking with physical obstacles.
- Telerehabilitation using a Kinect camera-based interactive telerehabilitation system may not be beneficial for improving muscle strength, functional mobility, balance, and falls and fear of falling after stroke when compared to Conventional physiotherapy.
- Virtual reality augmented robot-assisted gait training with conventional care may not be beneficial for improving activities of daily living, gait speed, functional mobility, balance, and falls and fear of falling after stroke when compared to Robot-assisted gait training with conventional care.
- Speed-Interactive Pedaling Training with Virtual Reality may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and balance after stroke when compared to Pedaling Training.
- Virtual Reality or Virtual Reality with Proprioceptive Neuromuscular Facilitation may not be beneficial for improving motor recovery, sensory and proprioceptive function, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Virtual Reality may not be beneficial for improving motor recovery after stroke when compared to Virtual Reality with Proprioceptive Neuromuscular Facilitation.
- Cognitive motor exergaming training may be beneficial for improving biomechanical balance measures, but not gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Conventional training (stretching, strengthening, balance and endurance training).

- Dual-task (virtual reality-based UL training while walking on treadmill) may be beneficial for improving gait speed, balance, and falls and fear of falling, but not functional mobility, after stroke when compared to Single task treadmill walking.
- Robotic-assisted gait training (Lokomat-Pro) with VR may be beneficial for improving neurophysiological measures and functional mobility, but not spasticity, after stroke when compared to Robotic-assisted gait training (Lokomat-Nanos).
- The literature is mixed regarding the effect of Virtual reality with cognitive load with conventional rehabilitation on biomechanical gait measures and gait speed after stroke when compared to Treadmill walking with virtual environment with conventional rehabilitation.
- Virtual walking training (virtual reality) with rehabilitation program may be beneficial for improving gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Treadmill gait training with rehabilitation.
- One session daily high intensity Videogame exercises with medical massage may be beneficial for improving activities of daily living after stroke when compared to Standard physical therapy with medical massage.
- Two sessions daily high intensity Videogame exercises with medical massage may not be beneficial for improving activities of daily living after stroke when compared to Standard physical therapy with medical massage.
- Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- Auditory stimulation with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- Virtual Reality with Proprioceptive Neuromuscular Facilitation may not be beneficial for improving motor recovery, sensory and proprioceptive function, and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Anodal Cerebellar tDCS with Xbox Kinect games may be beneficial for improving falls and fear of falling, but not sensory and proprioceptive function, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Anodal M1 tDCS with Xbox Kinect games.
- Anodal Cerebellar tDCS with Xbox Kinect games may be beneficial for improving sensory and proprioceptive function, functional mobility, balance, and falls and fear of falling, but not gait speed and gait endurance, after stroke when compared to Sham Stimulation Group with Xbox Kinect games.
- Anodal M1 tDCS with Xbox Kinect games may be beneficial for improving sensory and proprioceptive function, functional mobility, and balance, but not gait speed, gait endurance, and falls and fear of falling, after stroke when compared to Sham Stimulation Group with Xbox Kinect games.
- Xbox training during nodal tDCS stimulation to motor cortex may be beneficial for improving balance, but not gait speed, gait endurance, functional mobility, and falls and fear of falling, after stroke when compared to Sham tDCS with xbox training.

A.27 Electromechanical and Robotic Devices (Table 27)

Key Points

- Robot Assisted Gait Training may be beneficial for improving muscle strength and falls and fear of falling, but not motor recovery, biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy and Overground Gait Training; the literature is mixed regarding neurophysiological measures.
- Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not be beneficial for improving biomechanical gait measures, muscle strength, spasticity, gait endurance, and functional mobility after stroke when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2.5mA).

- Gait Trainer GT I (Rehastim) may not be beneficial for improving motor recovery, gait speed, gait endurance, and functional mobility after stroke when compared to Overground gait training.
- Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation may not be beneficial for improving muscle strength, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Gait Trainer GT II (Rehastim) with Regular rehabilitation.
- Early Robot Assisted Gait Training may be beneficial for improving neurophysiological measures after stroke when compared to Late Start Robot Assisted Gait Training.
- Robot Assisted Gait Training may be beneficial for improving gait endurance, but not biomechanical balance measures, gait speed, functional mobility, and balance, after stroke when compared to Balance Training.
- Electromechanical Gait Training may be beneficial for improving gait speed and functional mobility, but not biomechanical balance measures, activities of daily living, and balance, after stroke when compared to Conventional Treatment or No Treatment; the literature is mixed regarding muscle strength and gait endurance.
- Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy may not be beneficial for improving muscle strength, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Electromechanical gait trainer with Conventional physical therapy.
- Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy may not be beneficial for improving biomechanical balance measures, muscle strength, activities of daily living, gait endurance, functional mobility, and balance after stroke when compared to Electromechanical gait trainer with Conventional therapy.
- End-Effector Gait Training may be beneficial for improving motor recovery, but not neurophysiological measures, gait speed, and functional mobility, after stroke when compared to Body Weight Supported Treadmill.
- Electromechanical gait trainer therapy with Conventional rehabilitation may be beneficial for improving functional mobility, but not motor recovery, spasticity, and gait speed, after stroke when compared to Body weight-supported treadmill training with Conventional rehabilitation.
- Exoskeleton Systems may be beneficial for improving neurophysiological measures and falls and fear of falling, but not motor recovery, biomechanical gait measures, muscle strength, spasticity, range of motion, aerobic measures, sensory and proprioceptive function, activities of daily living, gait speed, gait endurance, functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy or Overground Gait Training; the literature is mixed regarding biomechanical balance measures.
- ExoAtlet exoskeleton exercises with rehabilitation may be beneficial for improving muscle strength, activities of daily living, gait speed, and functional mobility, but not spasticity, after stroke when compared to Ortorent MOTO pedal trainer for active-passive training with rehabilitation; the literature is mixed regarding balance.
- Robot Assisted Gait Training (Lokomat) with Conventional Therapy may be beneficial for improving activities of daily living, gait endurance, functional mobility, and quality of life, but not motor recovery and aerobic measures, after stroke when compared to Robot Assisted Gait Training (Lokomat); the literature is mixed regarding gait speed.
- Resistance load Robotic gait system training may not be beneficial for improving gait speed, gait endurance, and balance after stroke when compared to Assistance Robotic gait system training.
- Therapist-assisted locomotor training may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Robotic-assisted locomotor training.
- Exoskeleton Systems may be beneficial for improving biomechanical gait measures, neurophysiological measures, gait speed, and falls and fear of falling, but not motor recovery, gait endurance, and balance, after stroke when compared to Treadmill Training; the literature is mixed regarding functional mobility.
- 30% weight robot gait training with general physical therapy may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to 50% weight robot gait training with general physical therapy.
- 30% weight robot gait training with general physical therapy may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to 70% weight robot gait training with general physical therapy.

- Home-based overground Robot-assisted gait training (AlterG Bionic Leg) with Usual care may be beneficial for improving gait speed, gait endurance, functional mobility, and balance, but not aerobic measures and activities of daily living, after stroke when compared to Physical Activity with Usual physiotherapy.
- Exoskeleton Gait Training may be beneficial for improving gait speed, gait endurance, and balance, but not motor recovery, neurophysiological measures, pain, functional mobility, falls and fear of falling, and quality of life, after stroke when compared to Functional Task-Specific Training.
- Exoskeleton Systems Administration Method may be beneficial for improving motor recovery and biomechanical gait measures, but not activities of daily living, functional mobility, and balance, after stroke when compared to Therapist controlled robot-assisted gait training; the literature is mixed regarding gait speed.
- Exoskeleton Portable Devices may be beneficial for improving muscle strength, spasticity, and neurophysiological measures, but not motor recovery, biomechanical gait measures, gait speed, gait endurance, and balance, after stroke when compared to Overground Gait Training or Stretching or Sham Ankle Foot Orthosis; the literature is mixed regarding range of motion and functional mobility.
- Robot-assisted training with Power-assisted ankle robot with Conventional training may be beneficial for improving gait speed, but not functional mobility and balance, after stroke when compared to Robot-assisted training with Swing-controlled ankle robot with Conventional training.
- Exoskeleton Portable Devices may be beneficial for improving gait speed, but not motor recovery, muscle strength, spasticity, range of motion, activities of daily living, and balance, after stroke when compared to Stretching; the literature is mixed regarding biomechanical gait measures.
- Exoskeleton Portable Devices with Ankle Foot Orthosis may be beneficial for improving motor recovery, gait speed, and functional mobility, but not biomechanical gait measures, spasticity, gait endurance, and balance, after stroke when compared to Sham Ankle Foot Orthosis.
- Robotic-Assisted Gait Training and Restraint may be beneficial for improving motor recovery, activities of daily living, balance, and range of motion, but not gait speed, functional mobility, falls and fear of falling, and biomechanical gait measures, after stroke when compared to Robot-assisted (Lokomat) walking training with arm fixation with conventional care.
- Robotics Combined with Virtual Reality may be beneficial for improving motor recovery and neurophysiological measures, but not spasticity, activities of daily living, gait speed, balance, and falls and fear of falling, after stroke when compared to Robotics, Robotics Combined with Auditory Stimulation or Conventional Training; the literature is mixed regarding functional mobility.
- Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy may be beneficial for improving motor recovery and muscle strength, but not activities of daily living, gait speed, functional mobility, and balance, after stroke when compared to Auditory stimulation with robot- assisted gait training (Treadmill) and conventional physical therapy.
- Galvanic vestibular stimulation may not be beneficial for improving balance after stroke when compared to Gait training (Lokomat) or Physiotherapy with visual feedback.
- The literature is mixed regarding the effect of Gait training (Lokomat) on balance after stroke when compared to Physiotherapy with visual feedback.
- Assist-as-needed robot- assisted gait training for unaffected limb with fully-assisted robot-assisted training for affected limb may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, range of motion, gait speed, functional mobility, and balance after stroke when compared to Assist-as-needed robot- assisted gait training for affected limb with fully-assisted robot-assisted training for unaffected limb.
- Robot-assisted Trunk Training may be beneficial for improving biomechanical balance measures and balance after stroke when compared to Conventional Therapy.
- Gait training with Gait Exercise Assist Robot (GEAR) may be beneficial for improving functional mobility, but not biomechanical gait measures, gait speed, and quality of life, after stroke when compared to Gait training with treadmill; the literature is mixed regarding gait endurance.
- Gait Training with Gait Exercise Assist Robot (GEAR) may be beneficial for improving activities of daily living, but not motor recovery, after stroke when compared to Overground Gait Training.
- Robotic Verticalization with functional electrical stimulation may be beneficial for improving motor recovery, muscle strength, neurophysiological measures, and balance after stroke when compared to

Conventional therapy; the literature is mixed regarding aerobic measures and sensory and proprioceptive function.

- Robotic-assisted Stretching may be beneficial for improving biomechanical balance measures and range of motion, but not biomechanical gait measures and gait speed, after stroke when compared to Conventional Therapy.
- Regent Suit with Neuromotor rehabilitation may be beneficial for improving activities of daily living, gait speed, and balance, but not biomechanical gait measures and aerobic measures, after stroke when compared to Neuromotor rehabilitation.
- Vibration on sole of foot may be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Contact on Sole of Foot with No Vibration.
- Robot-Assisted Gait Training with Visuomotor feedback may be beneficial for improving neurophysiological measures, but not quality of life, after stroke when compared to Robot-Assisted Gait Training; the literature is mixed regarding motor recovery.
- Robotics with Treadmill Training and Virtual Reality may be beneficial for improving motor recovery, but not biomechanical gait measures, biomechanical balance measures, spasticity, range of motion, pain, activities of daily living, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Seated Training.
- Robotic gait training with Exoskeleton ExoAthlet with Conventional physiotherapy may be beneficial for improving quality of life, but not activities of daily living and gait endurance, after stroke when compared to Robotic gait training with Lokomat Free-D with Conventional physiotherapy.
- Ankle robot training low frequency, low intensity may not be beneficial for improving motor recovery and range of motion after stroke when compared to ankle robot training high frequency, low intensity or ankle robot training low frequency, high intensity or ankle robot training high frequency, high intensity.
- Robot-Guided Ankle Proprioceptive Training with Thermal Stimulation may be beneficial for improving motor recovery, range of motion, gait speed, and balance after stroke when compared to Conventional Therapy.
- Robot-Assisted Gait Training with Robotic Balance Platform may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, muscle strength, pain, activities of daily living, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Robot-Assisted Gait Training Alone.
- Robot-Assisted Gait Training may be beneficial for improving motor recovery, but not activities of daily living, after stroke when compared to Upper Limb Therapy.
- Robot-Assisted Gait Training with Balance Training may not be beneficial for improving functional mobility, balance, and falls and fear of falling after stroke when compared to Balance Training Alone; the literature is mixed regarding motor recovery.
- Robot-Assisted Gait Training may be beneficial for improving motor recovery and aerobic measures, but not muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Home-Based Exercise Program.
- Ankle-knee-hip Interlimb coordinated humanoid robot + Conventional Physical therapy may not be beneficial for improving motor recovery, biomechanical gait measures, and spasticity after stroke when compared to Gait training + Conventional PT.
- Healbot T (Exoskeleton) with pelvic motion on may be beneficial for improving neurophysiological measures, but not biomechanical gait measures and gait speed, after stroke when compared to Healbot T (Exoskeleton) with pelvic motion off.
- Progressive reducing assistance force during robot-assisted gait training + conventional PT may be beneficial for improving muscle strength, activities of daily living, functional mobility, and balance after stroke when compared to Full assistance force during robot-assisted gait training + conventional PT.
- Gait trainer device (REHA-STIM) may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, activities of daily living, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Conventional rehabilitation (Bobath).
- 2x Lokomat gait training + 1x Conventional PT may not be beneficial for improving motor recovery, muscle strength, spasticity, gait speed, gait endurance, and functional mobility after stroke when compared to 2x Conventional PT + 1x Lokomat gait training.

- Daoyin with Conventional rehab may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional rehab.
- Daoyin with Conventional rehab may not be beneficial for improving motor recovery and balance after stroke when compared to Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab; the literature is mixed regarding activities of daily living.
- High definition transcranial direct current stimulation (dual) with Robot assisted gait training may be beneficial for improving activities of daily living, but not gait speed, functional mobility, and balance, after stroke when compared to Sham High definition transcranial direct current stimulation with Robot assisted gait training; the literature is mixed regarding motor recovery.
- Robotic Gait Training (Lokomat robotic exoskeleton) with Botulinum toxin injection may be beneficial for improving gait speed and gait endurance, but not spasticity, functional mobility, and balance, after stroke when compared to Botulinum toxin injection with Conventional physiotherapy.
- Acupuncture with Gait rehab robot training (AiWalker-I) and Conventional rehab may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Acupuncture with Conventional rehab.
- Robotic balance training with conventional rehabilitation may be beneficial for improving balance, but not motor recovery, biomechanical balance measures, muscle strength, activities of daily living, functional mobility, and falls and fear of falling, after stroke when compared to Conventional training.
- Brain-computer interface- controlled training robot with Conventional Physiotherapy may not be beneficial for improving motor recovery, neurophysiological measures, activities of daily living, and functional mobility after stroke when compared to Sham brain-computer interface-controlled training robot with Conventional Physiotherapy.
- Dynamic tilt table with robotic leg movement with functional electrical stimulation may be beneficial for improving gait speed, but not motor recovery, biomechanical gait measures, and range of motion, after stroke when compared to dynamic tilt table with robotic leg movement.
- Virtual reality augmented robot- assisted gait training with conventional care may not be beneficial for improving activities of daily living, gait speed, functional mobility, balance, and falls and fear of falling after stroke when compared to Robot-assisted gait training with conventional care.
- Brain-computer interface- operated lower limb rehabilitation robot may be beneficial for improving motor recovery, but not functional mobility and balance, after stroke when compared to Sham (Lower limb pedal training without image, video, sound hint); the literature is mixed regarding neurophysiological measures.
- Interactive Dynamic Scalp Acupuncture with lower-limb robot training (SA & LLRT simultaneously) and Basic Treatment may be beneficial for improving motor recovery, biomechanical gait measures, activities of daily living, gait endurance, and balance after stroke when compared to Scalp Acupuncture with Basic Treatment.
- Trunk stability robot training (3DBT-33) with conventional physical therapy may be beneficial for improving motor recovery and balance, but not functional mobility, after stroke when compared to Conventional Physical Therapy.
- Robot-assisted balance exercises may be beneficial for improving sensory and proprioceptive function, but not functional mobility and balance, after stroke when compared to Conventional care.
- Robotic tilt table (Erigo) therapy may be beneficial for improving muscle strength and quality of life after stroke when compared to Conventional physiotherapy.
- The literature is mixed regarding the effect of Haemorrhagic Stroke Erigo Robotic Tilt Table on motor recovery, muscle strength, spasticity, and quality of life after stroke when compared to Haemorrhagic Stroke Conventional Care or Ischemic Stroke Conventional Care.
- Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training may not be beneficial for improving biomechanical gait measures, muscle strength, spasticity, gait speed, and functional mobility after stroke when compared to Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training.
- Robotic Tilt table with Upper extremity exercises may be beneficial for improving muscle strength and quality of life after stroke when compared to Conventional therapy.

- Robotic ankle stretching exercises may be beneficial for improving biomechanical balance measures and range of motion, but not biomechanical gait measures and gait speed, after stroke when compared to Conventional stretching board.
- Robot-assisted gait training with Virtual reality may not be beneficial for improving muscle strength, gait speed, gait endurance, and functional mobility after stroke when compared to Robot-assisted gait training.
- Botulinum toxin A with Robot assisted Gait Training (RoboGait) and Conventional Physiotherapy may be beneficial for improving functional mobility and balance, but not spasticity and range of motion, after stroke when compared to Botulinum toxin A with Conventional Physiotherapy or 90min physical therapy 1session/d, 5d/wk, for 3wks.
- Robot-assisted gait training (Lokomat) with Virtual reality may be beneficial for improving neurophysiological measures and functional mobility, but not spasticity, after stroke when compared to Robot-assisted gait training (Lokomat).
- Robot-assisted gait training and anodal transcranial direct current stimulation over the leg motor cortex area may not be beneficial for improving gait speed and functional mobility after stroke when compared to Robot-assisted gait training only.
- Robot-assisted gait training and anodal transcranial direct current stimulation may not be beneficial for improving motor recovery, muscle strength, neurophysiological measures, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Robot-assisted gait training and sham stimulation.
- Botox (250U) With Robot- Assisted Gait Therapy may be beneficial for improving gait endurance, but not spasticity, after stroke when compared to Botox Alone.
- Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not be beneficial for improving muscle strength, spasticity, and functional mobility after stroke when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA); Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may result in lesser improvements in biomechanical gait measures and gait endurance when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA).
- Robot-assisted (Lokomat) gait training with functional electrical stimulation on the ankle dorsiflexor of affected side may not be beneficial for improving biomechanical gait measures, range of motion, gait speed, functional mobility, and balance after stroke when compared to Robot-assisted (Lokomat) gait training.
- Anodal transcranial direct current stimulation with Robot- assisted gait training may not be beneficial for improving gait speed, balance, quality of life, biomechanical gait measures, and gait endurance after stroke when compared to Sham transcranial direct current stimulation with Robot- assisted gait training; the literature is mixed regarding functional mobility.
- Anodal transcranial direct current stimulation with Robot- assisted gait training may be beneficial for improving biomechanical gait measures and functional mobility after stroke when compared to Gait training.
- Virtual reality robotic training (computer) may not be beneficial for improving biomechanical gait measures, gait speed, and gait endurance after stroke when compared to Robotic training.
- Lower Limb Robot with Conventional rehab may not be beneficial for improving motor recovery, activities of daily living, and balance after stroke when compared to Daoyin with Lower Limb Robot with Conventional rehab.
- 30% weight robot gait training with general physical therapy may be beneficial for improving gait speed, functional mobility, and balance after stroke when compared to Treadmill training with general physical therapy.

- Virtual reality with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- Auditory stimulation with robot- assisted gait training (Treadmill) with conventional physical therapy may be beneficial for improving muscle strength after stroke when compared to Conventional physical therapy with treadmill training.
- Robot-assisted gait training with Conventional care may not be beneficial for improving motor recovery, muscle strength, spasticity, activities of daily living, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Conventional gait training with Conventional care in patients with high motricity.
- Robot-assisted gait training with Conventional care may be beneficial for improving activities of daily living, gait endurance, functional mobility, and balance, but not muscle strength, spasticity, and gait speed, after stroke when compared to Conventional gait training with Conventional care in patients with low motricity.
- Overground gait training using E-Go device with Standard Physiotherapy may not be beneficial for improving motor recovery, activities of daily living, gait endurance, functional mobility, and balance after stroke when compared to Overground walking training with Standard Physiotherapy.
- 50% weight robot gait training with general physical therapy may be beneficial for improving gait speed, but not functional mobility and balance, after stroke when compared to Treadmill training with general physical therapy.
- 70% weight robot gait training with general physical therapy may be beneficial for improving gait speed, but not functional mobility and balance, after stroke when compared to Treadmill training with general physical therapy.

A.28 Functional Electrical Stimulation (Table 28)

Key Points

- Functional electrical stimulation Therapy or Sham Stimulation may be beneficial for improving biomechanical gait measures, muscle strength, spasticity, neurophysiological measures, aerobic measures, and gait speed, but not motor recovery, activities of daily living, gait endurance, functional mobility, balance, and quality of life, after stroke when compared to Conventional Therapy or Sham Stimulation.
- Rehabilitation with functional electrical stimulation may be beneficial for improving muscle strength, spasticity, neurophysiological measures, and functional mobility after stroke when compared to rehabilitation with Placebo stimulation.
- Functional electrical stimulation Combined with Gait Training may be beneficial for improving range of motion, aerobic measures, activities of daily living, and quality of life, but not biomechanical gait measures, spasticity, neurophysiological measures, gait speed, functional mobility, and balance, after stroke when compared to Gait Training or Conventional Therapy; the literature is mixed regarding motor recovery, muscle strength, and gait endurance.
- Cycling with functional electrical stimulation may be beneficial for improving motor recovery, but not biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, aerobic measures, activities of daily living, gait speed, gait endurance, and balance, after stroke when compared to Cycling with or without Sham functional electrical stimulation or Conventional Therapy; the literature is mixed regarding functional mobility.
- Interval Cycling with functional electrical stimulation may be beneficial for improving spasticity and range of motion, but not gait speed and balance, after stroke when compared to Linear Cycling with functional electrical stimulation; the literature is mixed regarding functional mobility.
- Treadmill Training with functional electrical stimulation may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, functional mobility, and balance after stroke when compared to Treadmill Training with or without Sham functional electrical stimulation; the literature is mixed regarding muscle strength and gait endurance.

- Robot-assisted Gait Training with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, biomechanical balance measures, muscle strength, range of motion, activities of daily living, gait speed, gait endurance, functional mobility, and balance after stroke when compared to Gait Training or Robot-assisted Gait Training.
- Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy may not be beneficial for improving muscle strength, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Electromechanical gait trainer with Conventional physical therapy.
- Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy may not be beneficial for improving biomechanical balance measures, muscle strength, activities of daily living, gait endurance, functional mobility, and balance after stroke when compared to Electromechanical gait trainer with Conventional therapy.
- Balance Training with functional electrical stimulation may be beneficial for improving neurophysiological measures and balance, but not biomechanical gait measures and gait speed, after stroke when compared to Balance Training or Conventional Care; the literature is mixed regarding functional mobility.
- Functional electrical stimulation with Proprioceptive Neuromuscular Facilitation may not be beneficial for improving functional mobility and balance after stroke when compared to Proprioceptive Neuromuscular Facilitation.
- Ankle Training with brain-computer interface-based functional electrical stimulation may be beneficial for improving gait speed, but not biomechanical gait measures, balance, and functional mobility, after stroke when compared to Ankle Training with functional electrical stimulation.
- Functional electrical stimulation with Tilt Table may be beneficial for improving motor recovery, muscle strength, neurophysiological measures, activities of daily living, gait speed, and balance, but not biomechanical gait measures and range of motion, after stroke when compared to Conventional Therapy or Simple Tilt Table; the literature is mixed regarding aerobic measures and sensory and proprioceptive function.
- Functional electrical stimulation with Motor Training on Rocker Board may be beneficial for improving spasticity and functional mobility, but not biomechanical balance measures, muscle strength, range of motion, and gait speed, after stroke when compared to Conventional Exercises.
- Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy may not be beneficial for improving biomechanical balance measures and gait speed after stroke when compared to Electromyography triggered neuromuscular electrical stimulation training (single electrical stimulation) with conventional physiotherapy.
- Functional electrical stimulation Muscle Stimulation may be beneficial for improving motor recovery, spasticity, gait speed, functional mobility, and balance, but not biomechanical balance measures, after stroke when compared to Electrical Muscle Stimulation.
- Four-channel functional electrical stimulation with physiotherapy may be beneficial for improving activities of daily living and balance, but not motor recovery, after stroke when compared to Dual-channel functional electrical stimulation with physiotherapy.
- Four-Channel functional electrical stimulation may be beneficial for improving activities of daily living and balance, but not functional mobility, after stroke when compared to Dual-Channel functional electrical stimulation or Sham; the literature is mixed regarding motor recovery.
- Four-channel functional electrical stimulation with Conventional therapy may be beneficial for improving motor recovery and activities of daily living, but not functional mobility and balance, after stroke when compared to Dual-channel functional electrical stimulation with Conventional therapy.
- Faradic electrical stimulation with Task-oriented exercise may be beneficial for improving spasticity, but not functional mobility, after stroke when compared to Russian electrical stimulation with Task-oriented exercises; the literature is mixed regarding range of motion.
- Faradic Electrical Stimulation may not be beneficial for improving range of motion and functional mobility after stroke when compared to Russian Electrical Stimulation; the literature is mixed regarding spasticity.
- Mirror Therapy with Functional Electrical Stimulation may be beneficial for improving motor recovery, range of motion, and gait speed after stroke when compared to Conventional Therapy.

- Transcranial direct current stimulation with conventional therapy may be beneficial for improving motor recovery, activities of daily living, and functional mobility, but not neurophysiological measures, after stroke when compared to Functional electrical stimulation with conventional therapy.
- Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation with conventional rehabilitation.
- Gait training with transcranial direct current stimulation with conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation.
- Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation.
- Ankle foot orthosis with gait training may be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility, but not aerobic measures, after stroke when compared to functional electrical stimulation with gait training.
- Peroneal Nerve functional electrical stimulation (Foot-drop Stimulator) may not be beneficial for improving motor recovery, aerobic measures, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Ankle-Foot Orthosis.
- Peroneal Nerve functional electrical stimulation (Foot-drop Stimulator) may not be beneficial for improving motor recovery, biomechanical gait measures, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Conventional Therapy or Gait Training; the literature is mixed regarding spasticity and range of motion.
- Peroneal Nerve Stimulation may not be beneficial for improving biomechanical gait measures, spasticity, range of motion, neurophysiological measures, activities of daily living, gait speed, and functional mobility after stroke when compared to Sham Stimulation or Conventional Therapy; the literature is mixed regarding motor recovery.
- Core Muscle Training with functional electrical stimulation may be beneficial for improving muscle strength, gait speed, and balance after stroke when compared to Core Muscle Training Alone; the literature is mixed regarding functional mobility.
- FES with Perturbation Training may be beneficial for improving biomechanical gait measures and falls and fear of falling after stroke when compared to Perturbation Training Alone.
- Over-Ground Gait Training + BWS Treadmill Training + Functional electrical stimulation with intramuscular electrodes may not be beneficial for improving biomechanical gait measures after stroke when compared to Over-Ground Gait Training + BWS Treadmill Training.
- Mirror feedback with functional electrical stimulation may be beneficial for improving motor recovery, biomechanical gait measures, balance, and falls and fear of falling after stroke when compared to Conventional rehab with functional electrical stimulation.
- Bicephalic transcranial direct current stimulation with gait training and foot drop stimulator (Walkaide orthosis) may not be beneficial for improving motor recovery, neurophysiological measures, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with gait training and foot drop stimulator.
- Contralaterally controlled functional electrical stimulation with rehab may not be beneficial for improving range of motion, neurophysiological measures, activities of daily living, gait speed, and functional mobility after stroke when compared to Neuromuscular electrical stimulaion (neuromuscular electrical stimulation) with rehab; the literature is mixed regarding motor recovery.
- M1 anodal transcranial direct current stimulation with functional electrical stimulation and Conventional care may be beneficial for improving spasticity and balance after stroke when compared to 20min/d functional electrical stimulation with Conventional care or 20min/d functional electrical stimulation and 20min/d conventional care, 5d/wk, for 2wks; the literature is mixed regarding neurophysiological measures.

- Bicephalic Transcranial direct-current stimulation with Footdrop stimulator and Treadmill gait training may not be beneficial for improving spasticity, gait endurance, functional mobility, and quality of life after stroke when compared to Sham transcranial direct-current stimulation with Footdrop stimulator and treadmill gait training.
- Foot drop stimulator with treadmill training and Basic rehabilitation training may be beneficial for improving biomechanical gait measures, spasticity, range of motion, neurophysiological measures, and functional mobility after stroke when compared to Foot drop stimulator training with Basic rehabilitation training.
- Modified Dynamic Ankle Foot Orthosis (including functional electrical stimulation) with Conventional physiotherapy may be beneficial for improving gait speed after stroke when compared to Conventional physiotherapy.
- Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation) may be beneficial for improving biomechanical balance measures, but not neurophysiological measures and balance, after stroke when compared to Functional electric stimulation (functional electrical stimulation).
- Mirror therapy with Functional electrical stimulation may be beneficial for improving motor recovery, range of motion, and gait speed after stroke when compared to Conventional therapy or 50 min, 4d/wk, for 2wks CT 1wk washout.
- Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer) may be beneficial for improving motor recovery, but not gait speed, gait endurance, and functional mobility, after stroke when compared to Conventional Care.
- Gait training with functional electrical stimulation and Action observation may be beneficial for improving biomechanical balance measures and gait speed after stroke when compared to Gait training with functional electrical stimulation.
- Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation may not be beneficial for improving muscle strength, activities of daily living, gait speed, functional mobility, and balance after stroke when compared to Gait Trainer GT II (Rehastim) with Regular rehabilitation.
- Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation may be beneficial for improving functional mobility, but not muscle strength, activities of daily living, and balance, after stroke when compared to Overground gait training.
- Botulinum toxin A (500U) with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, spasticity, and range of motion after stroke when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching.
- Botulinum toxin type A injection with functional electrical stimulation and Conventional physiotherapy may be beneficial for improving aerobic measures and gait speed, but not motor recovery, spasticity, and quality of life, after stroke when compared to Conventional physiotherapy.
- Rehabilitation with electromyography biofeedback may be beneficial for improving range of motion after stroke when compared to Conventional rehabilitation; the literature is mixed regarding biomechanical gait measures.
- Customized unilateral ankle-foot orthosis may be beneficial for improving functional mobility after stroke when compared to No Intervention.
- Four-channel functional electrical stimulation (FES) with Standard physiotherapy may be beneficial for improving activities of daily living after stroke when compared to Sham FES with Standard physiotherapy.
- Dual-channel FES with Standard physiotherapy may be beneficial for improving activities of daily living after stroke when compared to Sham FES with Standard physiotherapy.
- Common peroneal nerve stimulation may not be beneficial for improving neurophysiological measures after stroke when compared to Low Frequency rTMS.

A.29 Neuromuscular Electrical Stimulation (NMES) (Table 29)

Key Points

- Cyclic neuromuscular electrical stimulation may be beneficial for improving muscle strength, spasticity, and range of motion, but not neurophysiological measures, after stroke when compared to Conventional Therapy or Neurodevelopmental Techniques.
- Neuromuscular electrical stimulation Therapy may not be beneficial for improving biomechanical gait measures, spasticity, range of motion, activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Conventional Therapy; the literature is mixed regarding motor recovery, muscle strength, and balance.
- Neuromuscular electrical stimulation on tibialis anterior with ambulation training may not be beneficial for improving biomechanical gait measures, muscle strength, range of motion, and gait speed after stroke when compared to neuromuscular electrical stimulation on medial gastrocnemius with ambulation training; the literature is mixed regarding spasticity.
- Electromyography-triggered neuromuscular electrical stimulation may not be beneficial for improving motor recovery, spasticity, range of motion, activities of daily living, and functional mobility after stroke when compared to Conventional Therapy.
- Interferential Current neuromuscular electrical stimulation with Air-pump Massage may be beneficial for improving spasticity, gait speed, functional mobility, and balance after stroke when compared to Sham.
- Passive Movement Training with cyclic neuromuscular electrical stimulation may be beneficial for improving gait speed, but not spasticity, after stroke when compared to Passive Movement Training.
- Passive Movement Training with cyclic neuromuscular electrical stimulation may be beneficial for improving gait speed, but not spasticity, after stroke when compared to Cyclic neuromuscular electrical stimulation.
- Cyclic neuromuscular electrical stimulation may not be beneficial for improving activities of daily living after stroke when compared to Trunk/Core Training; the literature is mixed regarding balance.
- Trunk neuromuscular electrical stimulation with Core muscle training may not be beneficial for improving activities of daily living and balance after stroke when compared to Trunk neuromuscular electrical stimulation.
- Sensory threshold neuromuscular electrical stimulation with Conventional therapy may be beneficial for improving spasticity and range of motion, but not functional mobility, after stroke when compared to Conventional therapy.
- Contralaterally controlled neuromuscular electrical stimulation with conventional therapy may be beneficial for improving motor recovery and activities of daily living, but not neurophysiological measures, after stroke when compared to neuromuscular electrical stimulation with conventional therapy.
- Contralaterally Controlled neuromuscular electrical stimulation may not be beneficial for improving range of motion, neurophysiological measures, activities of daily living, gait speed, functional mobility, biomechanical gait measures, and muscle strength after stroke when compared to Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation; the literature is mixed regarding motor recovery.
- Mirror Therapy with Cyclic neuromuscular electrical stimulation may be beneficial for improving muscle strength, gait speed, and balance, but not motor recovery, spasticity, range of motion, gait endurance, and functional mobility, after stroke when compared to Conventional Therapy.
- Neuromuscular electrical stimulation Therapy may not be beneficial for improving motor recovery, activities of daily living, and balance after stroke when compared to Mirror Therapy.
- Neuromuscular electrical stimulation with Exercise Therapy may not be beneficial for improving motor recovery, gait speed, gait endurance, functional mobility, balance, and quality of life after stroke when compared to Exercise Therapy.
- Neuromuscular electrical stimulation with Walking Training may be beneficial for improving gait speed, but not motor recovery, muscle strength, spasticity, and activities of daily living, after stroke when compared to Conventional Walking Training with Ankle-Foot Orthosis; the literature is mixed regarding functional mobility.
- Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not be beneficial for improving muscle strength, spasticity, range of motion, gait speed, and gait endurance after stroke when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles.

- Neuromuscular electrical stimulation with Passive Ankle Movement Training may not be beneficial for improving motor recovery, biomechanical gait measures, muscle strength, range of motion, sensory and proprioceptive function, gait speed, functional mobility, balance, and falls and fear of falling after stroke when compared to neuromuscular electrical stimulation Alone.
- Neuromuscular electrical stimulation Stimulation may be beneficial for improving spasticity, but not gait speed and functional mobility, after stroke when compared to Sham Stimulation.
- Neuromuscular electrical stimulation (NMES) may not be beneficial for improving spasticity, neurophysiological measures, and gait speed after stroke when compared to Sham NMES.
- Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) may be beneficial for improving range of motion, but not balance, after stroke when compared to Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy).
- Electromyography-triggered Pedaling training may be beneficial for improving motor recovery, biomechanical gait measures, and gait speed after stroke when compared to Pedaling training; the literature is mixed regarding neurophysiological measures.
- Proprioceptive neuromuscular facilitation trunk pattern with electromyography-triggered functional electrical stimulation may not be beneficial for improving functional mobility and balance after stroke when compared to proprioceptive neuromuscular facilitation trunk pattern.
- Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy may not be beneficial for improving biomechanical balance measures and gait speed after stroke when compared to Electromyography triggered neuromuscular electrical stimulation training (single electrical stimulation) with conventional physiotherapy.
- Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy may be beneficial for improving gait speed, but not biomechanical balance measures, after stroke when compared to Conventional rehabilitation.
- Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation may be beneficial for improving activities of daily living and balance after stroke when compared to rehabilitation.
- Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation may not be beneficial for improving activities of daily living and balance after stroke when compared to Neuromuscular Electrical Stimulation with Early Rehabilitation.
- Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation) may be beneficial for improving biomechanical balance measures, but not neurophysiological measures and balance, after stroke when compared to Functional electric stimulation (functional electrical stimulation).
- Tele-supervising rehabilitation (physical therapy with electromyography-neuromuscular electrical stimulation) may not be beneficial for improving activities of daily living, balance, and quality of life after stroke when compared to Conventional Care.
- Neuromuscular Electrical Stimulation may be beneficial for improving neurophysiological measures, but not muscle strength, after stroke when compared to Occupational Therapy.
- Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy may be beneficial for improving muscle strength and balance, but not spasticity, gait endurance, and functional mobility, after stroke when compared to Conventional therapy.
- Neuromuscular electrical stimulation (Walkaide) with walking training and conventional therapy may be beneficial for improving gait speed, but not motor recovery, muscle strength, spasticity, and activities of daily living, after stroke when compared to Walking training with ankle-foot- orthosis and conventional therapy; the literature is mixed regarding functional mobility.

A.30 Transcutaneous Electrical Nerve Stimulation (TENS) (Table 30)

Key Points

- Transcutaneous electrical nerve stimulation may be beneficial for improving biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, and neurophysiological measures, but not range of motion, pain, activities of daily living, functional mobility, and quality of life, after stroke when compared to Sham Stimulation, Conventional Therapy or No Treatment; the literature is mixed regarding motor recovery, sensory and proprioceptive function, and gait speed.
- Transcutaneous electrical nerve stimulation may be beneficial for improving neurophysiological measures after stroke when compared to Cryotherapy.
- Transcutaneous electrical nerve stimulation with rehabilitation may not be beneficial for improving muscle strength, spasticity, and functional mobility after stroke when compared to Sham transcutaneous electrical nerve stimulation with rehabilitation.
- Transcutaneous electrical nerve stimulation with exercise may not be beneficial for improving spasticity and activities of daily living after stroke when compared to Sham transcutaneous electrical nerve stimulation with exercise, transcutaneous electrical nerve stimulation only, or No Treatment.
- Transcutaneous electrical nerve stimulation with Task-related Training may be beneficial for improving spasticity, but not range of motion and functional mobility, after stroke when compared to Task-related training.
- Transcutaneous electrical nerve stimulation (60min) with Task- related training may be beneficial for improving range of motion after stroke when compared to transcutaneous electrical nerve stimulation (30min) with Task- related training; the literature is mixed regarding spasticity.
- Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy may be beneficial for improving balance, but not gait endurance and quality of life, after stroke when compared to C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy; the literature is mixed regarding functional mobility.
- TENS with Task-related training or Sham TENS and Task- related training may be beneficial for improving muscle strength and balance after stroke when compared to No active treatment (health education).
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving balance, but not muscle strength, after stroke when compared to Sham transcutaneous electrical nerve stimulation with Task- related training.
- Transcutaneous electrical nerve stimulation may be beneficial for improving gait speed after stroke when compared to No treatment.
- TENS with Task-related training may be beneficial for improving gait speed, gait endurance, and functional mobility, but not spasticity, after stroke when compared to TENS; the literature is mixed regarding muscle strength.
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving gait speed and functional mobility, but not muscle strength, spasticity, and gait endurance, after stroke when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training.
- Transcutaneous electrical nerve stimulation may not be beneficial for improving spasticity, gait speed, gait endurance, and functional mobility after stroke when compared to Placebo transcutaneous electrical nerve stimulation with Task- related training; the literature is mixed regarding muscle strength.
- Transcutaneous electrical nerve stimulation may be beneficial for improving gait speed after stroke when compared to No active treatment.
- Transcutaneous electrical nerve stimulation with Task-related training may be beneficial for improving gait speed, but not muscle strength and spasticity, after stroke when compared to transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training.
- Unilateral transcutaneous electrical nerve stimulation may not be beneficial for improving motor recovery, muscle strength, and balance after stroke when compared to Bilateral transcutaneous electrical nerve stimulation; the literature is mixed regarding functional mobility.

- Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation may be beneficial for improving activities of daily living and balance after stroke when compared to Neuromuscular Electrical Stimulation with Early Rehabilitation.
- Transcutaneous electrical nerve stimulation vs Conventional Therapy may not be beneficial for improving activities of daily living and balance after stroke when compared to neuromuscular electrical stimulation or Conventional Therapy.
- Therapeutic ultrasound with Home exercises & conventional therapy may not be beneficial for improving spasticity and range of motion after stroke when compared to transcutaneous electrical nerve stimulation with Home exercises & conventional therapy.
- Therapeutic ultrasound with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Electroacupuncture may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Low-intensity, high-frequency transcutaneous electrical nerve stimulation (2Hz) electrostimulation.
- Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care may be beneficial for improving neurophysiological measures and balance after stroke when compared to Conventional care.
- Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care may be beneficial for improving neurophysiological measures and balance after stroke when compared to Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care.
- Balance Training with transcutaneous electrical nerve stimulation may be beneficial for improving neurophysiological measures after stroke when compared to Sham transcutaneous electrical nerve stimulation with Balance Training or Conventional Care; the literature is mixed regarding balance.
- Trunk Training with Balance Training and transcutaneous electrical nerve stimulation may be beneficial for improving sensory and proprioceptive function, but not balance, after stroke when compared to Treadmill Training and Placebo transcutaneous electrical nerve stimulation.
- Transcutaneous electrical nerve stimulation with Heel-raise-lower training may be beneficial for improving muscle strength, spasticity, and gait speed after stroke when compared to Placebo transcutaneous electrical nerve stimulation with Heel-raise-lower training.
- Instructed sensory training with transcutaneous electrical nerve stimulation may not be beneficial for improving sensory and proprioceptive function, functional mobility, falls and fear of falling, and quality of life after stroke when compared to Uninstructed sensory training with transcutaneous electrical nerve stimulation.
- Transcutaneous electrical nerve stimulation with Taping and Exercise may be beneficial for improving muscle strength, spasticity, and gait speed after stroke when compared to transcutaneous electrical nerve stimulation with Exercise.
- Multi-sensorimotor training (Stabilize-T and Reha bar exercises with transcutaneous electrical nerve stimulation) and Conventional physical therapy may be beneficial for improving sensory and proprioceptive function, but not balance, after stroke when compared to Treadmill training with placedo transcutaneous electrical nerve stimulation and conventional physical therapy.
- Sit-to-stand training with transcutaneous electrical nerve stimulation and conventional therapy may be beneficial for improving biomechanical balance measures and spasticity, but not muscle strength, after stroke when compared to Sit-to-stand training with sham transcutaneous electrical nerve stimulation and conventional therapy.
- Low-dose Botulinum toxin (100U) with transcutaneous electrical nerve stimulation may not be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to High-dose Botulinum toxin (400U) with Sham electrical stimulation.
- TENS with Task-related training may be beneficial for improving gait speed after stroke when compared to No treatment.

A.31 Muscle Vibration (Table 31)

Key Points

- Whole Body Vibration may be beneficial for improving range of motion, but not motor recovery, biomechanical gait measures, biomechanical balance measures, muscle strength, spasticity, neurophysiological measures, aerobic measures, activities of daily living, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life, after stroke when compared to Sham Stimulation, No Stimulation, or Conventional Care.
- Matrix Rhythm Therapy may be beneficial for improving spasticity, range of motion, gait speed, functional mobility, and balance, but not biomechanical gait measures, after stroke when compared to Bobath Therapy.
- Whole Body Vibration may not be beneficial for improving muscle strength, sensory and proprioceptive function, activities of daily living, functional mobility, and balance after stroke when compared to Musical Exercise Therapy.
- Balance Training with Whole Body Vibration may not be beneficial for improving functional mobility and balance after stroke when compared to Conventional Rehabilitation; the literature is mixed regarding activities of daily living.
- Whole Body Vibration with Treadmill Training may be beneficial for improving biomechanical gait measures and gait speed, but not gait endurance, after stroke when compared to Treadmill Training.
- Local Muscle Vibration may be beneficial for improving biomechanical balance measures, muscle strength, spasticity, gait speed, functional mobility, balance, and falls and fear of falling, but not biomechanical gait measures, range of motion, neurophysiological measures, and activities of daily living, after stroke when compared to Conventional Therapy or Sham Muscle Vibration; the literature is mixed regarding motor recovery.
- Gastrocnemius vibration with conventional may be beneficial for improving gait speed, but not motor recovery, spasticity, neurophysiological measures, and activities of daily living, after stroke when compared to Tibialis anterior vibration with conventional; the literature is mixed regarding functional mobility.
- High-frequency (26 Hz) Whole-body vibration training with therapy may not be beneficial for improving balance after stroke when compared to Low-frequency (13 Hz) Whole-body vibration training with therapy; the literature is mixed regarding functional mobility.
- Comparing Whole-Body Vibration Intensity may be beneficial for improving spasticity, but not functional mobility, balance, muscle strength, aerobic measures, gait endurance, and falls and fear of falling, after stroke when compared to Sham with therapy.
- High frequency (30Hz) whole body vibration may not be beneficial for improving neurophysiological measures and gait endurance after stroke when compared to Low frequency (20Hz) whole body vibration.
- Whole Body Vibration may be beneficial for improving functional mobility and balance after stroke when compared to Strength Training.
- Vibrational and Heated Stone-Needle Therapy with Meridian Dredging Exercise may be beneficial for improving spasticity, but not quality of life, after stroke when compared to Meridian Dredging Exercise; the literature is mixed regarding motor recovery.
- Vibration on sole of foot may be beneficial for improving biomechanical balance measures and falls and fear of falling after stroke when compared to Contact on sole of foot with No vibration.
- Neuromuscular Electrical Stimulation may be beneficial for improving neurophysiological measures, but not muscle strength, after stroke when compared to Occupational Therapy.
- Task-Specific Training with Whole-Body Vibration Treatment (With an increase in frequency, sets, and time) may not be beneficial for improving muscle strength and balance after stroke when compared to Task-Specific Training with Sham Vibration.
- 30 Hz Whole Body Vibration may be beneficial for improving neurophysiological measures, but not spasticity, after stroke when compared to Non-Whole Body Vibration.

A.32 Additional Afferent and Peripheral Stimulation Methods (Table 32)

Key Points

- Tactile Sensory Stimulation may not be beneficial for improving biomechanical gait measures, sensory and proprioceptive function, functional mobility, and balance after stroke when compared to Conventional Care; the literature is mixed regarding biomechanical balance measures.
- Afferent Electrical Stimulation with Mirror Therapy may be beneficial for improving muscle strength, gait speed, and balance, but not biomechanical gait measures and spasticity, after stroke when compared to Sham.
- Intermittent Pneumatic Compression may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional Therapy.
- Laser Photo-biomodulation may be beneficial for improving gait endurance and functional mobility after stroke when compared to Sham.
- Sensory Training with Trunk Training may be beneficial for improving sensory and proprioceptive function, but not activities of daily living, gait endurance, and balance, after stroke when compared to Trunk Training Alone.
- Sensory Training may not be beneficial for improving balance after stroke when compared to Conventional Therapy.
- Instructed Sensory Training with transcutaneous electrical nerve stimulation may not be beneficial for improving sensory and proprioceptive function, functional mobility, falls and fear of falling, and quality of life after stroke when compared to Uninstructed Sensory Training with transcutaneous electrical nerve stimulation.
- Transcutaneous Auricular Vagus Nerve Stimulation with or without transcranial direct current stimulation may be beneficial for improving motor recovery, biomechanical gait measures, range of motion, activities of daily living, functional mobility, and balance after stroke when compared to Conventional Therapy.
- Tactile stimulation and mobilization + task specific gait training may not be beneficial for improving muscle strength, range of motion, gait speed, and functional mobility after stroke when compared to task specific gait training + unlimited textured insole wearing.
- NeuroDevelopmental rehabilitation + Center of pressure movement track in dynamic mode may be beneficial for improving gait speed, but not biomechanical balance measures and functional mobility, after stroke when compared to Neurodevelopmental rehabilitation + Center of pressure movement track training in static mode.

A.33 Remote Ischemic Conditioning (Table 33)

Key Points

- Remote Ischemic Conditioning may not be beneficial for improving muscle strength and neurophysiological measures after stroke when compared to Sham or Conventional Therapy; the literature is mixed regarding gait speed.

A.34 Thermal Stimulation and Cryotherapy (Table 34)

Key Points

- Thermal Stimulation may be beneficial for improving motor recovery, muscle strength, neurophysiological measures, and functional mobility, but not aerobic measures, activities of daily living, and balance, after stroke when compared to Sham or No Stimulation; the literature is mixed regarding spasticity.
- Transcutaneous electrical nerve stimulation may be beneficial for improving neurophysiological measures after stroke when compared to Cryotherapy.
- Cryotherapy may be beneficial for improving spasticity, but not biomechanical gait measures and muscle strength, after stroke when compared to Sham.

- Cryotherapy with Physical Therapy with Ankle foot Orthosis may be beneficial for improving spasticity and range of motion, but not neurophysiological measures, after stroke when compared to Physical Therapy with Ankle foot Orthosis.
- Ankle Proprioceptive Training with Thermotherapy may be beneficial for improving biomechanical gait measures, biomechanical balance measures, gait speed, and balance after stroke when compared to Conventional Therapy.
- Robot guided ankle proprioceptive training with Thermal tactile stimulation and Conventional therapy may be beneficial for improving motor recovery, range of motion, gait speed, and balance after stroke when compared to Conventional Therapy.

A.35 Extracorporeal Shockwave Therapy and Therapeutic Ultrasound (Table 35)

Key Points

- Extracorporeal Shockwave Therapy may be beneficial for improving biomechanical gait measures, muscle strength, and spasticity, but not motor recovery, range of motion, neurophysiological measures, pain, activities of daily living, gait speed, and gait endurance, after stroke when compared to Sham or Conventional Therapy.
- Extracorpeal shockwave therapy may not be beneficial for improving spasticity after stroke when compared to extracorporeal shockwave therapy with Isokinetic strength training; the literature is mixed regarding neurophysiological measures.
- Focused Shockwave Therapy may not be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to Radial Shockwave Therapy.
- Extracorporeal Shock-wave Therapy on Muscle Belly (0.068 0.093 mJ/mm², 1,500 shots) may not be beneficial for improving spasticity after stroke when compared to Sham Extracorporeal Shock- wave Therapy (sound only).
- Therapeutic Ultrasound may not be beneficial for improving motor recovery, spasticity, and range of motion after stroke when compared to Sham or Conventional Therapy; the literature is mixed regarding neurophysiological measures.
- Radial Extracorpeal Shock Wave Therapy with Visual Feedback Balance Training may be beneficial for improving motor recovery, biomechanical balance measures, spasticity, and range of motion, but not balance, after stroke when compared to Sham with Visual Feedback Balance Training; the literature is mixed regarding functional mobility.
- Therapeutic ultrasound with Home exercises & conventional therapy may not be beneficial for improving spasticity and range of motion after stroke when compared to transcutaneous electrical nerve stimulation with Home exercises & conventional therapy.
- Therapeutic ultrasound with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Therapeutic ultrasound may not be beneficial for improving muscle strength, spasticity, range of motion, neurophysiological measures, and functional mobility after stroke when compared to Radial extracorporeal shock wave therapy (radial extracorporeal shockwave therapy).
- Double dose extracorporeal shockwave therapy may be beneficial for improving functional mobility, but not spasticity and range of motion, after stroke when compared to Single dose extracorpeal shockwave therapy.

A.36 Repetitive Peripheral Magnetic Stimulation (Table 36)

Key Points

- Repetitive Peripheral Magnetic Stimulation may be beneficial for improving neurophysiological measures, but not muscle strength, after stroke when compared to neuromuscular electrical stimulation, Muscle Vibration, and Conventional therapy.
- Repetitive Peripheral Magnetic Stimulation may be beneficial for improving motor recovery and muscle strength, but not range of motion, after stroke when compared to Sham.

A.37 Repetitive Transcranial Magnetic Stimulation (rTMS) (Table 37)

Key Points

- Low frequency (1Hz) repetitive transcranial magnetic stimulation may be beneficial for improving motor recovery, biomechanical gait measures, neurophysiological measures, activities of daily living, gait endurance, functional mobility, and balance, but not spasticity, gait speed, and quality of life, after stroke when compared to Sham Stimulation; the literature is mixed regarding biomechanical balance measures.
- Primary motor area repetitive transcranial magnetic stimulation may not be beneficial for improving motor recovery after stroke when compared to Supplementary motor area repetitive transcranial magnetic stimulation; Primary motor area repetitive transcranial magnetic stimulation may result in lesser improvements in neurophysiological measures and balance when compared to Supplementary motor area repetitive transcranial magnetic stimulation.
- High Frequency (>1Hz) repetitive transcranial magnetic stimulation may be beneficial for improving biomechanical balance measures, spasticity, gait speed, and balance, but not muscle strength, aerobic measures, gait endurance, and functional mobility, after stroke when compared to Sham Stimulation; the literature is mixed regarding motor recovery, neurophysiological measures, and activities of daily living.
- High frequency repetitive transcranial magnetic stimulation (10Hz) with Conventional therapy may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Low frequency repetitive transcranial magnetic stimulation (1Hz) with Conventional therapy; the literature is mixed regarding neurophysiological measures.
- High Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation may be beneficial for improving biomechanical balance measures and balance after stroke when compared to Low Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation; the literature is mixed regarding motor recovery, neurophysiological measures, and activities of daily living.
- Ipsilesional repetitive transcranial magnetic stimulation (3Hz) with Physical therapy may be beneficial for improving neurophysiological measures after stroke when compared to Contralesional repetitive transcranial magnetic stimulation (1Hz) with Physical therapy.
- Low frequency (3Hz) repetitive transcranial magnetic stimulation with conventional care may not be beneficial for improving motor recovery, neurophysiological measures, and activities of daily living after stroke when compared to High frequency (10Hz) repetitive transcranial magnetic stimulation with conventional care.
- Combined High and Low Frequency repetitive transcranial magnetic stimulation may be beneficial for improving motor recovery, but not neurophysiological measures and functional mobility, after stroke when compared to Therapy.
- Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not be beneficial for improving neurophysiological measures and activities of daily living after stroke when compared to Sham repetitive transcranial magnetic stimulation; the literature is mixed regarding motor recovery.
- Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not be beneficial for improving motor recovery, neurophysiological measures, and activities of daily living after stroke when compared to Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy.
- High Frequency repetitive transcranial magnetic stimulation Combined with Treadmill Training may be beneficial for improving motor recovery, gait speed, gait endurance, and functional mobility, but not neurophysiological measures, after stroke when compared to Treadmill Training.

- Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation may be beneficial for improving muscle strength, neurophysiological measures, and gait speed after stroke when compared to Ankle Strengthening.
- Ankle Strengthening may be beneficial for improving muscle strength, neurophysiological measures, and gait speed after stroke when compared to repetitive transcranial magnetic stimulation.
- The literature is mixed regarding the effect of High Frequency repetitive transcranial magnetic stimulation with Cathodal transcranial direct current stimulation on motor recovery after stroke when compared to repetitive transcranial magnetic stimulation.
- Low Frequency (1Hz) repetitive transcranial magnetic stimulation may be beneficial for improving biomechanical gait measures, range of motion, and neurophysiological measures after stroke when compared to Conventional Therapy.
- Repetitive transcranial magnetic stimulation Combined with Cycling Exercise may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and balance after stroke when compared to Cycling Exercise Alone.
- Repetitive transcranial magnetic stimulation Combined with Virtual/Augmented Reality Gait Training may be beneficial for improving motor recovery and gait speed, but not biomechanical gait measures, muscle strength, and neurophysiological measures, after stroke when compared to Virtual/Augmented Reality Gait Training Alone; the literature is mixed regarding balance.
- Repetitive transcranial magnetic stimulation Combined with Motor Relearning may be beneficial for improving motor recovery, spasticity, and neurophysiological measures, but not functional mobility, after stroke when compared to Motor Relearning Alone.
- Mirror therapy with Repetitive transcranial magnetic stimulation may be beneficial for improving biomechanical balance measures, but not functional mobility and balance, after stroke when compared to Mirror therapy with Sham stimulation.
- LF-rTMS with Conventional rehab may be beneficial for improving biomechanical gait measures, range of motion, activities of daily living, gait speed, and balance, but not motor recovery, after stroke when compared to Sham rTMS with Conventional rehab.
- Cathodal tDCS with rTMS (1Hz) with conventional therapy may not be beneficial for improving motor recovery, neurophysiological measures, and activities of daily living after stroke when compared to Anodal tDCS with rTMS (1Hz) with conventional therapy.
- LF-rTMS with Conventional rehab may be beneficial for improving motor recovery, biomechanical gait measures, range of motion, activities of daily living, gait speed, and balance after stroke when compared to Conventional rehab.
- Sham rTMS with Conventional rehab may be beneficial for improving motor recovery, biomechanical gait measures, range of motion, and activities of daily living, but not gait speed and balance, after stroke when compared to Conventional rehab.

A.38 Theta Burst Stimulation (TBS) (Table 38)

Key Points

- Intermittent Theta Burst Stimulation may not be beneficial for improving motor recovery, neurophysiological measures, activities of daily living, gait speed, and balance after stroke when compared to Sham Stimulation.
- Cerebellar Intermittent Theta Burst Stimulation may be beneficial for improving biomechanical gait measures, gait speed, and balance, but not motor recovery, neurophysiological measures, and functional mobility, after stroke when compared to Sham; the literature is mixed regarding activities of daily living.
- Peripheral Intermittent Theta Burst Stimulation may be beneficial for improving spasticity after stroke when compared to Sham.
- Intermittent theta burst stimulation unilateral cerebellar area (CB Single group) may not be beneficial for improving balance after stroke when compared to intermittent theta burst stimulation Cerebellar primary motor cortex area (CB-M1 group) or intermittent theta burst stimulation Cerebellar Supplementary Motor Area (CB-SMA group).

- iTBS to M1 with Conventional physiotherapy may be beneficial for improving neurophysiological measures, but not activities of daily living and balance, after stroke when compared to iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy; iTBS to M1 with Conventional physiotherapy may result in lesser improvements in motor recovery when compared to iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy.
- iTBS to M1 with Conventional physiotherapy may be beneficial for improving neurophysiological measures, functional mobility, and balance, but not motor recovery and activities of daily living, after stroke when compared to Sham iTBS with Conventional physiotherapy.
- iTBS to contralateral cerebellar hemisphere with Conventional physiotherapy may be beneficial for improving motor recovery, neurophysiological measures, functional mobility, and balance, but not activities of daily living, after stroke when compared to Sham iTBS with Conventional physiotherapy.

A.39 Transcranial Direct Current Stimulation (tDCS) (Table 39)

Key Points

- Comparison of transcranial direct current stimulation Stimulation Conditions may be beneficial for improving spasticity, but not gait speed, biomechanical balance measures, quality of life, balance, and gait endurance, after stroke when compared to Sham transcranial direct current stimulation; the literature is mixed regarding biomechanical gait measures, neurophysiological measures, motor recovery, activities of daily living, sensory and proprioceptive function, muscle strength, and functional mobility.
- Anodal tDCS (2mA) may not be beneficial for improving motor recovery, biomechanical gait measures, neurophysiological measures, and functional mobility after stroke when compared to Sham tDCS.
- Anodal transcranial direct current stimulation (2mA) may not be beneficial for improving biomechanical gait measures after stroke when compared to Bilateral transcranial direct current stimulation (2mA) or Cathodal transcranial direct current stimulation (2mA); Anodal transcranial direct current stimulation (2mA) may result in lesser improvements in neurophysiological measures and gait speed when compared to Bilateral transcranial direct current stimulation (2mA) or Cathodal transcranial direct current stimulation (2mA).
- Bilateral transcranial direct current stimulation (2mA) may not be beneficial for improving biomechanical gait measures, neurophysiological measures, and gait speed after stroke when compared to Cathodal transcranial direct current stimulation (2mA).
- Bilateral tDCS (2mA) may be beneficial for improving biomechanical gait measures, neurophysiological measures, and gait speed, but not motor recovery, after stroke when compared to Sham tDCS.
- Cathodal tDCS (2mA) may be beneficial for improving neurophysiological measures and gait speed, but not biomechanical gait measures and motor recovery, after stroke when compared to Sham tDCS.
- Anodal transcranial direct current stimulation (2mA) with Conventional care may be beneficial for improving balance, but not quality of life, after stroke when compared to Cathodal transcranial direct current stimulation (2mA) with Conventional care.
- Bilateral transcranial direct current stimulation (tDCS) may not be beneficial for improving muscle strength and neurophysiological measures after stroke when compared to Sham tDCS.
- Dual transcranial direct current stimulation may be beneficial for improving gait endurance and functional mobility, but not biomechanical balance measures, after stroke when compared to Anodal transcranial direct current stimulation or Cathodal transcranial direct current stimulation; the literature is mixed regarding balance and falls and fear of falling.
- Anodal transcranial direct current stimulation with Conventional care may not be beneficial for improving motor recovery, muscle strength, neurophysiological measures, and activities of daily living after stroke when compared to Cathodal transcranial direct current stimulation with Conventional care.
- Anodal tDCS may be beneficial for improving range of motion, biomechanical balance measures, gait endurance, functional mobility, balance, and falls and fear of falling after stroke when compared to Sham tDCS.
- Transcranial direct current stimulation with Robot-assisted Gait Training may be beneficial for improving biomechanical gait measures and activities of daily living, but not motor recovery, muscle strength, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, and quality of life,

after stroke when compared to Sham transcranial direct current stimulation with Robot-assisted gait training.

- Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not be beneficial for improving biomechanical gait measures, muscle strength, spasticity, gait endurance, and functional mobility after stroke when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2.5mA).
- Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may not be beneficial for improving muscle strength, spasticity, and functional mobility after stroke when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA); Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation may result in lesser improvements in biomechanical gait measures and gait endurance when compared to Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2.5mA) or Robot-assisted gait training (G-EO), Anodal transcranial direct current stimulation (2mA) and Cathodal transcutaneous spinal direct current stimulation (2.5mA).
- Anodal transcranial direct current stimulation with Robot- assisted gait training may not be beneficial for improving biomechanical gait measures, gait speed, gait endurance, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with Robot- assisted gait training.
- Dual transcranial direct current stimulation with Task-oriented training may not be beneficial for improving gait speed, functional mobility, balance, quality of life, activities of daily living, and biomechanical gait measures after stroke when compared to Sham transcranial direct current stimulation with Task-oriented training; the literature is mixed regarding motor recovery.
- Cerebellar transcranial direct current stimulation with Split-belt treadmill training may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Sham cerebellar transcranial direct current stimulation with Split-belt treadmill training.
- Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training).
- Transcranial direct current stimulation with Ankle Motor Tracking and High-intensity speed-based treadmill training may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to High-intensity speed-based treadmill training.
- Transcranial direct current stimulation with Body weight supported treadmill training may be beneficial for improving gait speed, but not motor recovery and balance, after stroke when compared to transcranial direct current stimulation with Body weight supported treadmill training; the literature is mixed regarding functional mobility.
- Transcranial direct current stimulation with Task-related training may be beneficial for improving gait speed after stroke when compared to Task-related training; the literature is mixed regarding biomechanical gait measures.
- Anodal tDCS or Aerboic exercise with Anodal tDCS may not be beneficial for improving neurophysiological measures after stroke when compared to Aerobic exercise with Sham tDCS.
- Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training may not be beneficial for improving biomechanical gait measures, muscle strength, spasticity, gait speed, and functional mobility after stroke when compared to Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training.

- Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not be beneficial for improving neurophysiological measures and activities of daily living after stroke when compared to Sham repetitive transcranial magnetic stimulation; the literature is mixed regarding motor recovery.
- Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy may not be beneficial for improving neurophysiological measures and activities of daily living after stroke when compared to Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy; the literature is mixed regarding motor recovery.
- The literature is mixed regarding the effect of Dual-mode transcranial direct current stimulation (2mA) with repetitive transcranial magnetic stimulation (10Hz) on motor recovery after stroke when compared to repetitive transcranial magnetic stimulation (10Hz).
- Transcranial Direct Current Stimulation may be beneficial for improving spasticity and balance after stroke when compared to Functional Electrical Stimulation; the literature is mixed regarding neurophysiological measures.
- Transcranial direct current stimulation with conventional therapy may be beneficial for improving motor recovery, activities of daily living, and functional mobility, but not neurophysiological measures, after stroke when compared to Functional electrical stimulation with conventional therapy.
- Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation with conventional rehabilitation.
- Gait training with transcranial direct current stimulation with conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation.
- Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation may not be beneficial for improving biomechanical gait measures and gait speed after stroke when compared to Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation.
- Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy may be beneficial for improving balance and quality of life, but not gait speed, after stroke when compared to Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy.
- Transcranial direct current stimulation with Trunk Training may be beneficial for improving balance and quality of life, but not gait speed, after stroke when compared to Sham transcranial direct current stimulation with Trunk Training.
- Xbox training during anodal tDCS stimulation to cerebellum may not be beneficial for improving gait speed, gait endurance, functional mobility, and falls and fear of falling after stroke when compared to Xbox training during nodal tDCS stimulation to motor cortex; Xbox training during anodal tDCS stimulation to cerebellum may result in lesser improvements in balance when compared to Xbox training during nodal tDCS stimulation to motor cortex.
- Transcranial direct current stimulation with Videogame Training may not be beneficial for improving gait endurance after stroke when compared to Sham transcranial direct current stimulation with Videogame Training.
- Transcranial direct current stimulation with Gait Training may not be beneficial for improving activities of daily living, functional mobility, quality of life, biomechanical balance measures, motor recovery, and neurophysiological measures after stroke when compared to Sham transcranial direct current stimulation with Gait Training; the literature is mixed regarding balance.
- Transcranial direct current stimulation with Conventional Therapy may be beneficial for improving balance and gait speed, but not quality of life, after stroke when compared to Sham transcranial direct current stimulation with Conventional Therapy; the literature is mixed regarding functional mobility and motor recovery.
- Transcranial direct current stimulation with Treadmill Training may be beneficial for improving motor recovery and neurophysiological measures, but not range of motion and functional mobility, after stroke

when compared to Sham transcranial direct current stimulation with Treadmill Training; the literature is mixed regarding biomechanical gait measures and gait speed.

- Bilateral transcranial direct current stimulation and Treadmill may not be beneficial for improving motor recovery, biomechanical gait measures, and functional mobility after stroke when compared to Cathodal transcranial direct current stimulation and Treadmill; the literature is mixed regarding gait speed; Bilateral transcranial direct current stimulation and Treadmill may result in lesser improvements in neurophysiological measures when compared to Cathodal transcranial direct current stimulation and Treadmill.
- Transcranial direct current stimulation with Individualized Physiotherapy may not be beneficial for improving motor recovery, muscle strength, aerobic measures, and gait speed after stroke when compared to Sham transcranial direct current stimulation with Individualized Physiotherapy.
- Bihemisphere tDCS with individual physio plan may not be beneficial for improving motor recovery, spasticity, neurophysiological measures, and balance after stroke when compared to Unihemisphere tDCS with individual physio plan.
- Transcranial direct current stimulation with Foot Drop Stimulator and Treadmill Training may not be beneficial for improving spasticity, gait endurance, functional mobility, and quality of life after stroke when compared to Sham transcranial direct current stimulation with Foot Drop Stimulator and Treadmill Training.
- Transcranial direct current stimulation with Home-Based Exercise may not be beneficial for improving motor recovery, muscle strength, gait endurance, and functional mobility after stroke when compared to Sham transcranial direct current stimulation with Home-Based Exercise.
- Transcutaneous auricular vagus nerve stimulation with dual transcranial direct current stimulation may be beneficial for improving motor recovery, biomechanical gait measures, range of motion, activities of daily living, functional mobility, and balance after stroke when compared to Neurodevelopmental Bobath supplemented with Occupational Therapy.
- Cathodal tDCS with rTMS (1Hz) with conventional therapy may not be beneficial for improving motor recovery, neurophysiological measures, and activities of daily living after stroke when compared to Anodal tDCS with rTMS (1Hz) with conventional therapy.
- Anodal tDCS with Conventional therapy may not be beneficial for improving motor recovery, neurophysiological measures, and functional mobility after stroke when compared to Dual tDCS with Conventional therapy; Anodal tDCS with Conventional therapy may result in lesser improvements in muscle strength when compared to Dual tDCS with Conventional therapy.
- Cathodal tDCS with Conventional therapy may not be beneficial for improving motor recovery and neurophysiological measures after stroke when compared to Dual tDCS with Conventional therapy; Cathodal tDCS with Conventional therapy may result in lesser improvements in muscle strength and functional mobility when compared to Dual tDCS with Conventional therapy.
- Dual tDCS may be beneficial for improving biomechanical balance measures, gait endurance, functional mobility, balance, and falls and fear of falling after stroke when compared to Sham tDCS.
- Cathodal tDCS may be beneficial for improving biomechanical balance measures, gait endurance, functional mobility, balance, and falls and fear of falling after stroke when compared to Sham tDCS.
- Anodal tDCS with Conventional therapy may be beneficial for improving muscle strength, but not motor recovery, neurophysiological measures, and functional mobility, after stroke when compared to Sham tDCS with conventional rehab.
- Cathodal tDCS with Conventional therapy may not be beneficial for improving motor recovery, muscle strength, neurophysiological measures, and functional mobility after stroke when compared to Sham tDCS with conventional rehab.
- Dual tDCS with Conventional therapy may be beneficial for improving muscle strength and functional mobility, but not motor recovery and neurophysiological measures, after stroke when compared to Sham tDCS with conventional rehab.
- Xbox training during anodal tDCS stimulation to cerebellum may be beneficial for improving gait speed, functional mobility, and balance, but not falls and fear of falling, after stroke when compared to Sham tDCS with xbox training.

- Xbox training during nodal tDCS stimulation to motor cortex may be beneficial for improving balance, but not gait speed, functional mobility, and falls and fear of falling, after stroke when compared to Sham tDCS with xbox training.
- AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to 15min rest with High- intensity speed-based treadmill training.
- AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) may not be beneficial for improving motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, falls and fear of falling, and quality of life after stroke when compared to Transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training).
- Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training) may be beneficial for improving quality of life, but not motor recovery, neurophysiological measures, gait speed, gait endurance, functional mobility, balance, and falls and fear of falling, after stroke when compared to 15min rest with High- intensity speed-based treadmill training.
- Aerboic exercise with Anodal tDCS may not be beneficial for improving neurophysiological measures after stroke when compared to Aerobic exercise with Sham tDCS.
- Anodal tDCS may not be beneficial for improving neurophysiological measures after stroke when compared to Aerobic exercise with Sham tDCS.
- Anodal Cerebellar tDCS with Xbox Kinect games may be beneficial for improving falls and fear of falling, but not sensory and proprioceptive function, gait speed, gait endurance, functional mobility, and balance, after stroke when compared to Anodal M1 tDCS with Xbox Kinect games.
- Anodal Cerebellar tDCS with Xbox Kinect games may be beneficial for improving sensory and proprioceptive function, functional mobility, balance, and falls and fear of falling, but not gait speed, after stroke when compared to Sham Stimulation Group with Xbox Kinect games.
- Anodal M1 tDCS with Xbox Kinect games may be beneficial for improving sensory and proprioceptive function, functional mobility, and balance, but not gait speed and falls and fear of falling, after stroke when compared to Sham Stimulation Group with Xbox Kinect games.
- Bihemisphere tDCS with individual physio plan or Unihemisphere tDCS with individual physio plan may be beneficial for improving motor recovery, neurophysiological measures, and balance, but not spasticity, after stroke when compared to Sham tDCS with individual PT.
- Cathodal cerebellar stimulation (tcDCS) with cathodal spinal stimulation (tsDCS) and Robot-assisted Gait training may be beneficial for improving biomechanical gait measures, muscle strength, and gait endurance, but not spasticity and functional mobility, after stroke when compared to Anodal cerebral stimulation (tDCS) with cathodal spinal stimulation (tsDCS) and Robot-assisted Gait training.

A.40 Antidepressants (Table 40)

Key Points

- Fluoxetine may be beneficial for improving activities of daily living, but not quality of life, after stroke when compared to Placebo; the literature is mixed regarding motor recovery.
- Fluoxetine (20mg/d) may be beneficial for improving activities of daily living after stroke when compared to Maprotiline (150mg/d); the literature is mixed regarding motor recovery.
- Fluoxetine vs Placebo may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Maprotiline or Placebo.
- Escitalopram may not be beneficial for improving motor recovery, muscle strength, range of motion, gait speed, and gait endurance after stroke when compared to Placebo; the literature is mixed regarding neurophysiological measures.
- 20mg/d Citalopram & Physiotherapy may not be beneficial for improving motor recovery after stroke when compared to 20mg/day Fluoxetine & Physiotherapy.

- Fluoxetine (20mg/d) may not be beneficial for improving activities of daily living after stroke when compared to Placebo.
- Maprotiline (150mg/d) may not be beneficial for improving activities of daily living after stroke when compared to Placebo.
- 20mg/d Citalopram & Physiotherapy may be beneficial for improving motor recovery after stroke when compared to Placebo & Physiotherapy 1/d, for 90d medication/placebo & 1hr/d, 5d/wk, for 12wks PT.
- 20mg/day Fluoxetine & Physiotherapy may be beneficial for improving motor recovery after stroke when compared to Placebo & Physiotherapy 1/d, for 90d medication/placebo & 1hr/d, 5d/wk, for 12wks PT.
- Fluoxetine (20 mg) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Shu-Gan-Jie-Yu (2160 mg daily) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Shu-Gan-Jie-Yu capsule (720 mg) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.

A.41 Secondary Prevention Medications (Table 41)

Key Points

- Tirofiban may be beneficial for improving motor recovery, but not neurophysiological measures and sensory and proprioceptive function, after stroke when compared to Placebo.
- PF-3049423 may not be beneficial for improving activities of daily living and gait speed after stroke when compared to Placebo.
- Olmesartan may be beneficial for improving motor recovery, but not aerobic measures and activities of daily living, after stroke when compared to Amlodipine.
- Naftidrofuryl fumarate may not be beneficial for improving motor recovery after stroke when compared to Placebo.
- Nimodipine may not be beneficial for improving activities of daily living after stroke when compared to Placebo.
- DLBS1033 (Lumbrokinase) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional Therapy.
- Alteplase may be beneficial for improving motor recovery and balance after stroke when compared to Aspirin; the literature is mixed regarding activities of daily living.

A.42 Edaravone (Table 42)

Key Points

- Edaravone Injection may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional Treatment.
- Long term intravenous Edaravone (30mg) with Conventional care may be beneficial for improving muscle strength and gait speed, but not motor recovery, after stroke when compared to Short term intravenous Edaravone (30mg) with Conventional care.

A.43 Stimulants (Table 43)

Key Points

- Amphetamines may be beneficial for improving aerobic measures, but not motor recovery, activities of daily living, gait speed, gait endurance, functional mobility, and quality of life, after stroke when compared to Placebo.

- Amphetamine with Intensive Physiotherapy may not be beneficial for improving motor recovery after stroke when compared to Amphetamine with Conventional Physiotherapy.
- Amphetamine vs Placebo may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Levodopa or Placebo.
- Methylphenidate vs Placebo may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Levodopa or Placebo.

A.44 Dopamine Agonists (Table 44)

Key Points

- Levadopa or No Medication may be beneficial for improving motor recovery, but not activities of daily living and gait speed, after stroke when compared to Placebo or No Medication; the literature is mixed regarding functional mobility and quality of life.
- L-DOPA 100mg/d may be beneficial for improving gait speed, but not motor recovery and neurophysiological measures, after stroke when compared to Placebo.
- Methylphenidate (20mg/d) with conventional physiotherapy may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Levadopa (125mg/d) with conventional physiotherapy or Methylphenidate, Levadopa and conventional physiotherapy.
- Amphetamine (10mg/d) with Levodopa (50mg/d) may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Amphetamine placebo with Levodopa placebo.
- Ropinirole may not be beneficial for improving motor recovery, activities of daily living, gait speed, gait endurance, and quality of life after stroke when compared to Placebo.

A.45 Nerve Block Agents (Table 45)

Key Points

- Botulinum Toxin A (400 U) may be beneficial for improving spasticity, but not range of motion, after stroke when compared to Tibial nerve blockade (Phenol).
- 50% Ethyl alcohol injection (5mL) may not be beneficial for improving muscle strength, spasticity, and range of motion after stroke when compared to 5% Phenol injection (5mL).
- Tibial nerve block through thermocoagulation with ankle-foot orthosis may not be beneficial for improving motor recovery, spasticity, gait speed, and quality of life after stroke when compared to Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis.
- Curare Medications may not be beneficial for improving muscle strength and quality of life after stroke when compared to Homeopathic Medications.

A.46 Botulinum Toxin (Table 46)

Key Points

- Botulinum Toxin A may be beneficial for improving biomechanical gait measures, spasticity, gait endurance, and quality of life, but not biomechanical balance measures, muscle strength, aerobic measures, pain, activities of daily living, gait speed, and functional mobility, after stroke when compared to Placebo; the literature is mixed regarding motor recovery and range of motion.
- The literature is mixed regarding the effect of Botulinum Toxin A with Ankle-foot Orthosis on motor recovery, spasticity, activities of daily living, and balance after stroke when compared to Conventional rehabilitation.
- Botulinum toxin A (190-320U) with ankle-foot orthosis may be beneficial for improving biomechanical gait measures and spasticity, but not gait speed, after stroke when compared to Botulinum toxin A (190-320U).

- Botulinum toxin A (100U) with Serial casting and stretching and gait training may be beneficial for improving spasticity and range of motion, but not muscle strength, gait speed, gait endurance, and functional mobility, after stroke when compared to Botulinum toxin A (100U) with Taping and stretching and gait training.
- Botulinum Toxin A with Casting or Taping may not be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to Botulinum toxin A (75- 100U) with Sham taping and home exercises.
- Botulinum toxin A (100U) injection into tibialis posterior with ankle-foot adhesive taping may not be beneficial for improving biomechanical gait measures, spasticity, range of motion, and gait speed after stroke when compared to electromyography-guided Botulinum toxin A (190-320U) injection into several calf muscles.
- Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles may not be beneficial for improving muscle strength, spasticity, range of motion, gait speed, and gait endurance after stroke when compared to Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles.
- Botulinum Toxin A with Electrical Stimulation may not be beneficial for improving spasticity, activities of daily living, and gait endurance after stroke when compared to Botox Injections (50U- 120U) with neuromuscular electrical stimulation of Injected Agonist Muscles.
- Botulinum Toxin A with functional electrical stimulation may be beneficial for improving activities of daily living, gait speed, and aerobic measures, but not quality of life, after stroke when compared to Botulinum toxin A injection; the literature is mixed regarding motor recovery and spasticity.
- Botulinum toxin A (500U) with functional electrical stimulation may not be beneficial for improving biomechanical gait measures, spasticity, and range of motion after stroke when compared to Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching.
- Therapeutic ultrasound with Home exercises & conventional therapy may not be beneficial for improving spasticity and range of motion after stroke when compared to transcutaneous electrical nerve stimulation with Home exercises & conventional therapy.
- Therapeutic ultrasound with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy may result in lesser improvements in spasticity and range of motion when compared to Botulinum toxin A (200U) with Home exercises & conventional therapy.
- Botulinum Toxin A with transcutaneous electrical nerve stimulation may not be beneficial for improving spasticity, range of motion, and gait speed after stroke when compared to High-dose Botulinum toxin (400U) with Sham electrical stimulation.
- Botulinum toxin (200U) may be beneficial for improving spasticity, but not biomechanical gait measures, range of motion, gait speed, and functional mobility, after stroke when compared to Neurotomy.
- Botulinum Toxin A (400 U) may be beneficial for improving spasticity, but not range of motion, after stroke when compared to Phenol.
- Location of Injection may not be beneficial for improving spasticity, range of motion, gait speed, and functional mobility after stroke when compared to Distal gastrocnemius Botulinum toxin A injection 200U.
- Botulinum toxin A (100U) in mid belly of the gastrocnemius with placebo injected in distal of popliteal fossa may not be beneficial for improving motor recovery, spasticity, range of motion, and gait speed after stroke when compared to Botulinum toxin A (100U) at distal to the popliteal fossa with placebo injected in mid belly.
- Dosage of Injection may not be beneficial for improving motor recovery, biomechanical gait measures, range of motion, pain, and gait endurance after stroke when compared to Placebo; the literature is mixed regarding spasticity.
- Low-dose/low- concentration Botulinum toxin A may not be beneficial for improving gait speed after stroke when compared to Low-dose/high- concentration botulinum toxin A or High-dose/low- concentration botulinum toxin A or High-dose/high- concentration botulinum toxin A; the literature is mixed regarding spasticity and functional mobility.

- Botulinum toxin A with Conventional Therapy (300U) may be beneficial for improving spasticity, but not activities of daily living and gait speed, after stroke when compared to Botulinum toxin A with Conventional Therapy (100U).
- OnabotulinumtoxinA (200U) may not be beneficial for improving spasticity after stroke when compared to OnabotulinumtoxinA (300U); the literature is mixed regarding range of motion, pain, and functional mobility.
- Botulinum toxin A (167U) may not be beneficial for improving pain after stroke when compared to Botulinum toxin A (322U); Botulinum toxin A (167U) may result in lesser improvements in spasticity and gait speed when compared to Botulinum toxin A (322U).
- Botulinum toxin A (167U) may not be beneficial for improving pain after stroke when compared to Botulinum toxin A (540U); Botulinum toxin A (167U) may result in lesser improvements in spasticity when compared to Botulinum toxin A (540U); the literature is mixed regarding gait speed.
- Botulinum toxin A (322U) may not be beneficial for improving spasticity and pain after stroke when compared to Botulinum toxin A (540U); the literature is mixed regarding gait speed.
- Ultrasonography guided Botulinum toxin A (1000U) may not be beneficial for improving motor recovery, spasticity, activities of daily living, and gait speed after stroke when compared to Electrical stimulation guided Botulinum toxin A (1000U).
- Botulinum toxin A (200U) by ultrasonography may not be beneficial for improving spasticity and range of motion after stroke when compared to Botulinum toxin A (200U) by electrical stimulation.
- Botulinum toxin A (200U) by ultrasonography may not be beneficial for improving spasticity after stroke when compared to Botulinum toxin A (200U) by palpation; Botulinum toxin A (200U) by ultrasonography may result in lesser improvements in range of motion when compared to Botulinum toxin A (200U) by palpation.
- Botulinum toxin A (200U) by electrical stimulation may not be beneficial for improving spasticity after stroke when compared to Botulinum toxin A (200U) by palpation; Botulinum toxin A (200U) by electrical stimulation may result in lesser improvements in range of motion when compared to Botulinum toxin A (200U) by palpation.
- Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy may be beneficial for improving gait speed, but not spasticity, gait endurance, and functional mobility, after stroke when compared to Botulinum Toxin A Injection.
- Botox Combined with Robotics may be beneficial for improving gait speed, gait endurance, and functional mobility, but not spasticity and range of motion, after stroke when compared to Botox and Conventional Therapy; the literature is mixed regarding balance.
- Botulinum Toxin A with electromyography Biofeedback Treatment and Conventional Care may not be beneficial for improving biomechanical gait measures, spasticity, and gait speed after stroke when compared to Botulinum Toxin A with Conventional Care.
- Forward Treadmill Training with Botulinum Toxin may be beneficial for improving biomechanical balance measures and gait speed, but not biomechanical gait measures and spasticity, after stroke when compared to Backward Treadmill Training with Botulinum Toxin.
- Botulinum Toxin A may be beneficial for improving motor recovery, biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Conventional Therapy.
- Botulinum Toxin A (50-100U) + Isokinetic training may not be beneficial for improving biomechanical gait measures, muscle strength, spasticity, gait speed, and gait endurance after stroke when compared to Botulinum Toxin A (50-100U).
- Received co-injection of abobotulinumtoxinA (aboBoNT-A) in both the upper and lower limbs during treatment cycle 3 and 4 may not be beneficial for improving gait speed after stroke when compared to 1000-1500 U total botulinum toxin lower limb with upper limb injection.
- Botulinum neurotoxin Type A with functional electrical stimulation and conventional physiotherapy may not be beneficial for improving aerobic measures and gait speed after stroke when compared to Conventional physiotherapy.
- Backward treadmill training with botulinum toxin type A therapy may be beneficial for improving biomechanical balance measures and gait speed, but not biomechanical gait measures and spasticity, after stroke when compared to forward treadmill training with botulinum toxin type A therapy.

A.47 Antispastic Drugs (Table 47)

Key Points

- Tolperisone may be beneficial for improving spasticity and gait endurance, but not activities of daily living, after stroke when compared to Placebo.
- Intrathecal Baclofen may be beneficial for improving spasticity, but not motor recovery and activities of daily living, after stroke when compared to Placebo.
- Dantrolene may be beneficial for improving muscle strength and spasticity after stroke when compared to Placebo.
- Tizanidine (8mg, titrated up to max 20mg) may not be beneficial for improving muscle strength and spasticity after stroke when compared to Baclofen (20mg, titrated up to max 50mg).
- Tizanidine may not be beneficial for improving range of motion and activities of daily living after stroke when compared to Placebo; the literature is mixed regarding spasticity and neurophysiological measures.
- Magnesium Sulphate Iontophoresis may be beneficial for improving biomechanical gait measures and neurophysiological measures after stroke when compared to Stretching.

A.48 Cerebrolysin (Table 48)

Key Points

- Taping may not be beneficial for improving motor recovery after stroke when compared to no taping, sham taping, or conventional therapy.

A.49 4-Aminopyridine (Table 49)

Key Points

- Dalfampridine may not be beneficial for improving motor recovery, activities of daily living, and functional mobility after stroke when compared to Placebo; the literature is mixed regarding gait endurance.

A.50 Biologics and Targeted Molecular Therapies (Table 50)

Key Points

- Granulocyte-colony Stimulating Factor may not be beneficial for improving activities of daily living after stroke when compared to Placebo.
- Ganglioside GM1 may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Cutamesine may not be beneficial for improving activities of daily living and gait speed after stroke when compared to Placebo; the literature is mixed regarding motor recovery.
- Mesenchymal Stem Cell Injection may not be beneficial for improving motor recovery, muscle strength, neurophysiological measures, activities of daily living, and functional mobility after stroke when compared to Placebo or Conventional Therapy.
- Neuronal Cell may not be beneficial for improving motor recovery and quality of life after stroke when compared to Conventional Therapy.
- 5million implanted human neuronal cells with Conventional rehabilitation may not be beneficial for improving motor recovery after stroke when compared to 10million implanted human neuronal cells with Conventional rehabilitation.

A.51 Anabolic Steroids (Table 51)

Key Points

- Taping may be beneficial for improving muscle strength after stroke when compared to no taping, sham taping, or conventional therapy.

A.52 Supplements and Vitamins (Table 52)

Key Points

- Dietary Protein Supplement with Cycle Ergometer may be beneficial for improving motor recovery, neurophysiological measures, aerobic measures, gait endurance, functional mobility, and balance after stroke when compared to Carbohydrate Supplement with Cycle Ergometer.
- Leucine-enriched Amino Acid Supplementation may be beneficial for improving balance, but not neurophysiological measures, aerobic measures, activities of daily living, gait speed, gait endurance, and functional mobility, after stroke when compared to Resistance training exercise program; the literature is mixed regarding muscle strength.
- Primary motor area rTMS or Supplementary motor area rTMS may be beneficial for improving motor recovery and balance after stroke when compared to Sham rTMS.
- Soymilk Supplementation may be beneficial for improving gait speed and gait endurance, but not functional mobility, after stroke when compared to Placebo.
- Vitamin and comprehensive Dietary Supplementation may be beneficial for improving functional mobility, balance, and quality of life, but not muscle strength, gait speed, and motor recovery, after stroke when compared to regular meds (meds required for their clinical condition) with intensive rehabilitation treatment; the literature is mixed regarding gait endurance and activities of daily living.
- Primary motor area repetitive transcranial magnetic stimulation may be beneficial for improving motor recovery, neurophysiological measures, and balance after stroke when compared to Sham repetitive transcranial magnetic stimulation.
- Primary motor area repetitive transcranial magnetic stimulation may not be beneficial for improving motor recovery after stroke when compared to Supplementary motor area repetitive transcranial magnetic stimulation; Primary motor area repetitive transcranial magnetic stimulation may result in lesser improvements in neurophysiological measures and balance when compared to Supplementary motor area repetitive transcranial magnetic stimulation.
- Intermittent theta burst stimulation unilateral cerebellar area (CB Single group) may not be beneficial for improving balance after stroke when compared to intermittent theta burst stimulation Cerebellar primary motor cortex area (CB-M1 group) or intermittent theta burst stimulation Cerebellar Supplementary Motor Area (CB-SMA group).
- DLBS1033 supplement (Lumbrokinase) with therapy may be beneficial for improving motor recovery and activities of daily living after stroke when compared to therapy.
- Leucine enriched amino acid with resistant training may be beneficial for improving muscle strength, but not neurophysiological measures, after stroke when compared to Resistant training; the literature is mixed regarding activities of daily living.

A.53 Acupuncture and Massage (Table 53)

Key Points

- Acupuncture Therapy may be beneficial for improving biomechanical gait measures, biomechanical balance measures, spasticity, neurophysiological measures, gait speed, functional mobility, and balance, but not motor recovery, muscle strength, and activities of daily living, after stroke when compared to Conventional Therapy; the literature is mixed regarding quality of life.
- Acupuncture may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Physiotherapy or Acupuncture with PhysiotherapyNI.

- Contra-lateral Needling (acupuncture on unaffected limbs) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Traditional acupuncture.
- Acupuncture may be beneficial for improving motor recovery, spasticity, range of motion, activities of daily living, gait speed, functional mobility, and balance, but not biomechanical gait measures, pain, gait endurance, and quality of life, after stroke when compared to Sham; the literature is mixed regarding neurophysiological measures.
- Acupuncture Treatment may be beneficial for improving spasticity after stroke when compared to No Treatment; the literature is mixed regarding pain.
- Channel Palpation Guided Acupuncture may not be beneficial for improving motor recovery and quality of life after stroke when compared to Traditional Acupuncture.
- Scalp Acupuncture and Robot Assisted Training may be beneficial for improving motor recovery, biomechanical gait measures, activities of daily living, gait endurance, and balance after stroke when compared to Basic Treatment.
- Scalp Acupuncture may be beneficial for improving motor recovery, muscle strength, neurophysiological measures, activities of daily living, and quality of life after stroke when compared to Conventional Therapy or Other Modalities.
- Auricular Intradermal Acupuncture may be beneficial for improving motor recovery after stroke when compared to Conventional Therapy.
- Acupuncture with Manipulation may be beneficial for improving muscle strength, motor recovery, spasticity, neurophysiological measures, and activities of daily living after stroke when compared to Acupuncture.
- Eye Acupuncture may be beneficial for improving biomechanical gait measures after stroke when compared to Body Acupuncture.
- Multifaceted Alternative Medicine Approaches may be beneficial for improving muscle strength, range of motion, and gait speed, but not quality of life, neurophysiological measures, and aerobic measures, after stroke when compared to Meridian Dredging Exercise; the literature is mixed regarding spasticity, motor recovery, balance, and activities of daily living.
- Neuronavigation-assisted aspiration with electroacupuncture may be beneficial for improving spasticity and activities of daily living, but not motor recovery, after stroke when compared to Neuronavigation-assisted aspiration.
- Neuronavigation-assisted aspiration with electroacupuncture may be beneficial for improving spasticity and activities of daily living, but not motor recovery, after stroke when compared to Electroacupuncture.
- Neuronavigation-assisted aspiration may be beneficial for improving motor recovery and spasticity after stroke when compared to Electroacupuncture; the literature is mixed regarding activities of daily living.
- Electroacupuncture may be beneficial for improving motor recovery, but not spasticity and activities of daily living, after stroke when compared to Conservative therapy.
- Massage and other integrated rehabilitation techniques may be beneficial for improving gait speed, balance, and functional mobility, but not biomechanical gait measures and aerobic measures, after stroke when compared to Health education program; the literature is mixed regarding motor recovery, muscle strength, spasticity, activities of daily living, biomechanical balance measures, and quality of life.
- Chiropractic intervention may not be beneficial for improving neurophysiological measures after stroke when compared to Placebo chiropractic intervention.
- Dry Needling with Conventional Rehabilitation may be beneficial for improving spasticity, range of motion, gait speed, and balance after stroke when compared to Conventional Rehabilitation Alone.
- Acupuncture with Robot-Assisted Gait Training may be beneficial for improving biomechanical gait measures, gait speed, and functional mobility after stroke when compared to Acupuncture Alone.
- Virtual reality-assisted gait adaptation training with acupuncture and conventional physical therapy may be beneficial for improving gait speed and functional mobility, but not biomechanical balance measures and activities of daily living, after stroke when compared to Overground gait adaptation training with acupuncture and conventional physical therapy.
- Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy) may be beneficial for improving range of motion, but not balance, after stroke when

compared to Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy).

- Joint mobilization with acupuncture may be beneficial for improving activities of daily living, but not pain and gait speed, after stroke when compared to Conventional rehab; the literature is mixed regarding range of motion.
- Joint mobilization with acupuncture may be beneficial for improving range of motion and activities of daily living, but not pain and gait speed, after stroke when compared to Joint mobilization.
- Electroacupuncture with Conventional therapy may be beneficial for improving functional mobility, but not activities of daily living and gait speed, after stroke when compared to Conventional Therapy; the literature is mixed regarding motor recovery.
- One session daily high intensity Videogame exercises with medical massage may result in lesser improvements in aerobic measures when compared to physical therapy with medical massage or 60min/d care and 20min/d massage; the literature is mixed regarding biomechanical balance measures.
- One session daily high intensity Videogame exercises with medical massage may not be beneficial for improving biomechanical balance measures, aerobic measures, and activities of daily living after stroke when compared to two sessions daily high intensity Videogame exercises with medical massage.
- Electroacupuncture, usual care may not be beneficial for improving motor recovery, spasticity, and activities of daily living after stroke when compared to Usual care.
- Unani Medicine (Herbal and Massage) may be beneficial for improving functional mobility after stroke when compared to Western Medicine (Piracetam 800mg).
- Interferential current therapy (ICT) stimulation of gastrocnemius with air-pump massage and rehabilitation may be beneficial for improving spasticity, gait speed, functional mobility, and balance after stroke when compared to Placebo-ICT with air-pump massage and rehabilitation.
- Electroacupuncture with Conventional medication may be beneficial for improving motor recovery and neurophysiological measures after stroke when compared to Conventional medication.
- Electroacupuncture may not be beneficial for improving muscle strength, activities of daily living, and quality of life after stroke when compared to Sham transcutaneous electrical nerve stimulation.
- Electroacupuncture may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Low-intensity, high- frequency electrostimulation (80Hz).
- Electrical Acupuncture with Conventional Therapy may be beneficial for improving motor recovery after stroke when compared to Conventional therapy; the literature is mixed regarding activities of daily living.
- Electroacupuncture with Heparin, low molecular dextran, nimodipine may not be beneficial for improving motor recovery after stroke when compared to Heparin, low molecular dextran, nimodipine.
- One session daily high intensity Videogame exercises with medical massage may be beneficial for improving activities of daily living after stroke when compared to Standard physical therapy with medical massage.
- Two sessions daily high intensity Videogame exercises with medical massage may not be beneficial for improving activities of daily living after stroke when compared to Standard physical therapy with medical massage.
- Traditional acupuncture may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Convenional Care.

A.54 Electroacupuncture and Transcutaneous Electrical Acupoint Stimulation (Table 54)

Key Points

- Electroacupuncture Therapy may be beneficial for improving neurophysiological measures and functional mobility, but not spasticity, activities of daily living, and gait speed, after stroke when compared to Conventional Therapy; the literature is mixed regarding motor recovery.
- Electroacupuncture or transcutaneous electrical acupoint stimulation may not be beneficial for improving muscle strength, activities of daily living, and quality of life after stroke when compared to Sham.

- Electroacupuncture may not be beneficial for improving activities of daily living, gait speed, functional mobility, and quality of life after stroke when compared to Low-intensity, high- frequency electrostimulation (80Hz).
- Electroacupuncture with Heparin may not be beneficial for improving motor recovery after stroke when compared to Heparin.
- Neuronavigation-assisted aspiration with electroacupuncture may be beneficial for improving spasticity and activities of daily living, but not motor recovery, after stroke when compared to Neuronavigation-assisted aspiration.
- Neuronavigation-assisted aspiration with electroacupuncture may be beneficial for improving spasticity and activities of daily living, but not motor recovery, after stroke when compared to Electroacupuncture.
- Neuronavigation-assisted aspiration with electroacupuncture may be beneficial for improving motor recovery and spasticity after stroke when compared to Conservative therapy; the literature is mixed regarding activities of daily living.
- Neuronavigation-assisted aspiration may not be beneficial for improving motor recovery, spasticity, and activities of daily living after stroke when compared to Electroacupuncture.

A.55 Traditional Herbal Medicines (Table 55)

Key Points

- NeuroAid may not be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Other Herbal Medications may be beneficial for improving motor recovery, spasticity, activities of daily living, functional mobility, and balance, but not neurophysiological measures and quality of life, after stroke when compared to Placebo or No Medication.
- Qizhitongluo (500mg capsules) taken at breakfast and dinner with Placebo taken after lunch may be beneficial for improving motor recovery, but not neurophysiological measures, after stroke when compared to Naoxintong (400mg capsules) taken after each meal; the literature is mixed regarding activities of daily living.
- Other Herbal Medications may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional Therapy; the literature is mixed regarding spasticity.
- Chinese Traditional therapy (Bath in Chinese herbal medicine with Acupuncture with massage) and Conventional care may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Conventional care.
- Fluoxetine (20 mg) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Shu-Gan-Jie-Yu (2160 mg daily) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.
- Shu-Gan-Jie-Yu capsule (720 mg) may be beneficial for improving motor recovery and activities of daily living after stroke when compared to Placebo.

Conclusions Matrix

This table presents 1,426 conclusion statements across 55 intervention categories. Each row presents the intervention, the comparator, and its verdict in each outcome measure domain. Green = favourable, yellow = mixed evidence, red = not beneficial. A blank cell means the domain was not graded for that comparison.

Neurodevelopmental Techniques and Motor Relearning (33 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Bobath Concept Approach	Conventional Therapies												
Motor relearning with lower limb force-feedback	Motor relearning with upper limb force-feedback												
Motor Relearning	Bobath Concept Approach												
Modified constraint-induced movement therapy with Neurodevelopmental therapy	neurodevelopmental therapy												
Body weight supported Treadmill with Bobath physiotherapy	Bobath physiotherapy												
Sensory training with Trunk-centred Bobath exercise	Trunk-centred Bobath exercise												
Repetitive transcranial magnetic stimulation with Motor relearning procedure	Motor relearning procedure with Conventional rehabilitation												
Bobath with dry needling	Bobath												
Functional (adaptive) movement approach	functional approach for lower limb dressing												
Bobath Concept Approach with Task-Specific Training	Task-Specific Training												
Motor Relearning Programmes	Conventional Therapy or Sham												
Bobath Concept Approach Combined with Other Therapies	Bobath or Conventional Therapy												
Gaze stabilization exercises with balance exercises and neurodevelopmental treatment	Balance exercises with neurodevelopmental treatment												
Gaze stabilization exercises with balance exercises and neurodevelopmental treatment	gaze stabilization exercises with neurodevelopmental treatment												
Cervical mobilization with Bobath neurodevelopmental therapy	Sham spinal mobilization with Bobath neurodevelopmental therapy												
Sustained natural apophyseal glides with neurodevelopmental techniques	Maitland mobilization with neurodevelopmental techniques												
Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques	Talocrural joint only mobilization with neurodevelopmental techniques												
Motor relearning with electromyography biofeedback	Motor relearning												
Action observation of community ambulation with Functional training based on neurodevelopmental techniques	Landscape observation with Functional training based on neurodevelopmental techniques												
Muscle strengthening training to non-paralytic dorsiflexion muscles with neurodevelopmental therapy	Muscle strengthening training to paralytic dorsiflexion muscles with neurodevelopmental therapy												
Gait training with Rhythmic auditory stimulation and conventional therapy (bobath)	Gait training with conventional therapy (bobath)												
Inspiratory Muscle Training with Neurodevelopmental Bobath Treatment	Neurodevelopmental Bobath Treatment												
Whole body vibration with Neurodevelopmental treatment	Neurodevelopmental treatment												

Dry needling with Neurodevelopmental therapy	Neurodevelopmental therapy												
Early Bobath Approaches	Late Bobath Approaches												
Bobath Concept Approach	Task-Specific Training												
Motor Relearning Program with Obstacle walking	Motor Relearning Program												
Segmental mid-thoracic mobilization with neurodevelopmental therapy	Foam roller exercises with neurodevelopmental therapy												
Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)												
Matrix Rhythm Therapy (vibration) from thoracic spine to lower extremity with Bobath Therapy	Bobath Therapy												
Neurodevelopmental Bobath Concept Approach	proprioceptive neuromuscular facilitation method (proprioceptive neuromuscular facilitation)												
Musical motor feedback with Conventional gait therapy and Neurodevelopmental therapy	Conventional gait therapy with Neurodevelopmental therapy												
Cyclic neuromuscular electrical stimulation with Bobath	Bobath Approach												

Sit-to-Stand Training (12 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Sit-to-Stand Training (with Swiss ball)	Sit-to-stand Training (with stool)												
Continuous Auditory Feedback During Sit-to-Stand Training	No Feedback During Sit-to-stand Training												
Sit-to-Stand Training	Conventional Therapy												
Unstable Sit-to-Stand Support Surface	Stable Sit-to-Stand Support Surface												
Sit-to-stand Training with Asymmetrical Foot Position	Sit-to-stand Training with Symmetrical Foot Position												
Sit-to-Stand training with Visual Feedback	Sit-to-stand Training with physiotherapy												
Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy	Sit to Stand Training with physiotherapy												
Modified Sit-to-Stand Training	Conventional Therapy												
Intensive Sit-to-Stand Training	Regular Sit-to-Stand Training												
Standing postural symmetry training with a visual and auditory biofeedback trainer with repetitive sit-to-stand training and conventional rehabilitation	Conventional rehabilitation												
Sit-to-Stand training combined with transcutaneous electrical nerve stimulation	Sit-to-Stand Training												
Lateral Weight Transference Exercises in Sitting and Standing	Conventional Care												

Wheelchair Use (2 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Neater Uni-Wheelchair Attachment	Wheelchair												
Encouraging Self-Propulsion	Discouraging Self-Propulsion												

Trunk Training (32 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Trunk Training	Conventional Therapy												
Trunk Training with Tilted Platforms	Trunk Training with Horizontal Platforms												
Trunk Exercise with Unstable Surface	Trunk Exercise with Stable Surface or conventional therapy												
Trunk Training Combined with Robotics	Conventional Therapy												
Trunk Training Combined with Dual-Task Training	Trunk Training												
Trunk Training	Cognitive Training												
Kneeling Training	Treadmill Training												
Sensory training with Trunk-centred Bobath exercise	Trunk-centred Bobath exercise												
Trunk stabilization exercise using weights with general physiotherapy	Trunk stabilization without weights with general physiotherapy												
Trunk Training with Physio Equipment	Trunk stabilization exercises with conventional physical exercise												
Trunk stabilization exercise with Pelvic compression belt on paretic side and comprehensive rehabilitation therapy	Trunk stabilization exercise with Pelvic compression belt on non-paretic side and comprehensive rehabilitation therapy												
Stable trunk training with plinth	Unstable trunk training with Swiss ball												
Dynamic Neuromuscular Stabilization	Conventional Core Exercises												
Trunk Training with Visual or Auditory Feedback	Conventional Therapy												
Different Trunk Muscle Activation Exercises Compared to Each other	Bobath based trunk training with Conventional therapy												
Trunk stabilization exercise with abdominal hallowing with Conventional rehabilitation program	Trunk stabilization exercise with bracing maneuver with Conventional rehabilitation program												
Trunk Training with Delayed	Real-Time Visual Feedback												
Smartphone visual feedback for trunk control training with Conventional care	Conventional care												
Core stability exercises with real time feedback and conventional physical therapy	Core stability exercises with conventional physical therapy												
Aquatic therapy (Halliwick, Watsu, and Trunk Training)	Trunk control exercises Duration: 30min/d, 3d/wk, 4wks												
Metronome training with core strengthening and general balance exercises	Core strengthening with general balance exercises												
Core muscle training with Functional electrical stimulation	Core muscle training												
Segmental mid-thoracic mobilization with neurodevelopmental therapy	Foam roller exercises with neurodevelopmental therapy												

Core stability training on stable surface	Core stability training on unstable surface												
Bobath with Core stability training	Conventional physical therapy												
Space Balance 3D system for active trunk training with conventional physical and occupational therapy	General trunk training with Conventional physical and occupational physiotherapy												
Smartphone-based visual feedback trunk control training with Conventional rehabilitation	Conventional Rehabilitation												
Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit)	Trunk stabilization exercises												
Robot-assisted trunk control training with Conventional trunk stabilization exercise	Conventional trunk stabilization exercise with stretching exercise												
Trunk neuromuscular electrical stimulation with Core muscle training	Core Training												
Trunk neuromuscular electrical stimulation with Core muscle training	Trunk neuromuscular electrical stimulation												
Trunk Training with Balance Training and transcutaneous electrical nerve stimulation	Treadmill Training and Placebo transcutaneous electrical nerve stimulation												

Task-Specific Training (53 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Task-Specific Training	Conventional Therapy												
Task Oriented Gait Training	Conventional Training												
Task Specific Circuit Training	Conventional/Sham												
Task Specific Training Combined with Other Therapies	Task Specific Therapy												
Task Oriented Training with Tilt Table	Tilt Table Alone												
Constraint-induced movement therapy with task specific training	modified constraint-induced movement therapy with task specific training												
Task-oriented training with Virtual reality training	Task-oriented training												
Dual transcranial direct current stimulation with Task-specific training	Sham transcranial direct current stimulation with Task specific training												
Bihemispheric transcranial direct current stimulation with task oriented training	Sham transcranial direct current stimulation with task oriented therapy												
Task oriented training with altered sensory input	Conventional physical therapy												
Task Oriented sitting Reach Training	Sham Training												
Task Specific Treadmill Training	Treadmill Training												
Task Oriented Resistance Training	No Treatment												
Task oriented circuit gait training	Strength training of lower extremities												
Task-Specific Training	Orthoses												
Lower extremity task- specific rehabilitation	Upper extremity task- specific rehabilitation												
Task Oriented Leg Training	Body Weight Support Training												
Activity Repetition Training	Task Oriented Training												

Early supported discharge to Day unit focussed on task- oriented training	Traditional treatment													
Early supported discharge to Day unit focussed on task- oriented training	early supported discharge to patients home focussed on task-oriented training													
Task-specific training with cognitive sensorimotor exercise	Task-specific training with conventional physical therapy													
Lower body	Upper Body Task Specific Training													
High Intensity Task-Specific Training	Low Intensity Training or vs Conventional Therapy													
Tilt table one-leg standing training with Conventional rehabilitation	Tilt table progressive task-oriented training with Conventional rehabilitation													
Task-Specific Circuit Training	Group Activities													
Group Task-Oriented Circuit Training	Conventional Training													
Task-related Training combined with transcutaneous electrical nerve stimulation	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy													
Transcutaneous electrical nerve stimulation with Task-related training	transcutaneous electrical nerve stimulation													
Transcutaneous electrical nerve stimulation with Task-related training	Placebo transcutaneous electrical nerve stimulation with Task- related training													
Transcutaneous electrical nerve stimulation	Placebo transcutaneous electrical nerve stimulation with Task- related training													
Transcutaneous electrical nerve stimulation with Task-related training	transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training													
Task-Specific Training with Bobath Concept Approach	Task-Specific Training													
Bobath Concept Approach with Task specific practice	Task specific practice													
Manual therapy with task oriented training and home exercise program	conventional rehab													
Manual therapy with task oriented training and home exercise program	task oriented training with home exercise program													
Task-specific training with Mental practice (Motor Imagery)	Task-specific training													
Task-oriented training with mirror therapy	Task oriented training													
Armed4Stroke (Task-specific Exercise Telerehabilitation Program) with Usual Care	Usual Care													
Faradic electrical stimulation with Task-oriented exercise	Conventional care with task-oriented approach or 40 min conventional care 5d/wk, for 6wks													
Faradic electrical stimulation with Task-oriented exercise	Russian electrical stimulation with Task-oriented exercises													
Transcutaneous electrical nerve stimulation	No treatment													
Transcutaneous electrical nerve stimulation	No active treatment													
Transcranial direct current stimulation with Task-related training	Task-related training													
Single dose of botulinum toxin-A (500U) with Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting)	Single dose of botulinum toxin-A (500U) or Intensive rehabilitation program (includes electrical stimulation, task-specific training and casting)													

Task-Oriented Training	Speed Dependent Treadmill Training												
Task-specific training	Proprioceptive Neuromuscular Facilitation												
Task-oriented training with Abdominal drawing-in maneuver	Task-oriented training												
Task-Specific Training	Trunk Training												
Task-specific training with physiotherapy	physiotherapy												
Visual scanning exercises with task specific activities	Placebo eye exercises with task specific activities(not sham)												
Transcutaneous electrical nerve stimulation with Task-related training	No active treatment (health education)												
Transcutaneous electrical nerve stimulation with Task-related training	Sham transcutaneous electrical nerve stimulation with Task-related training												
Task-oriented approach training + Conventional PT	Task-oriented training only												

Constraint-Induced Movement Therapy (CIMT) (10 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Modified constraint-induced movement therapy Therapy or Conventional Rehabilitation	Neurodevelopmental Therapy or Conventional Rehabilitation												
Modified constraint-induced movement therapy Use Therapy	Forced Use Therapy												
Constraint-induced movement therapy with task specific training	modified constraint-induced movement therapy with task specific training												
Virtual reality Combined with constraint-induced movement therapy	virtual reality or Conventional Training												
Game-based constraint-induced movement therapy with Traditional physical therapy	General game-based training with Traditional physical therapy												
Constraint-induced movement therapy With Immobilization	Without Immobilization												
Constraint induced movement training on treadmill with home exercises	Treadmill training												
Game-based constraint-induced movement therapy with Traditional physical therapy	Traditional physical therapy												
Healbot no pelvic mode	Conventional gait training with treadmill												
Constraint-induced movement therapy uses number of repetition of tasks	control												

Non-Technological Overground Walking and Gait Training (50 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
High Intensity Overground Walking	Conventional Therapy												
Backward or Sideway Walking Training	Standing Practice or Conventional Therapy												
Gait Training with Postural Assistance Support	Gait Training with Conventional Support												
Accurate adaptability walking	Steady state walking												

Implicit Motor Learning with Walking	Explicit Motor Learning with Walking												
Overground walking with body weight supported	Treadmill training with body weight supported												
Overground gait training with Rhythmic auditory stimulation	Overground gait training												
Robot-assisted overground gait training	Conventional rehab												
Gait training program (half overground walking, half treadmill training) with Hip-assist robot	Gait training program (half overground walking, half treadmill training)												
Overground gait training using E-Go device with Physiotherapy	Overground walking training with Physiotherapy												
Gait Trainer GT I (Rehastim)	Overground gait training												
Gait training program (treadmill with overground walking) wearing a hip-assist robot	Gait training (treadmill training with over ground walking)												
Overground Walking	Treadmill Training												
Treadmill-based with augmented reality	Overground walking with physical obstacles												
Community-based gait training	conventional training												
Lateral Walking Training with Conventional physical therapy	Backward Walking Training with Conventional physical therapy												
Stair or Ramp Training	Flat Surface Gait Training												
15cm Stair Height Training with Comprehensive rehabilitation	10cm Stair Height Training with Comprehensive rehabilitation												
Gait Training with Motor Imagery	Conventional Gait Training												
Gait Training or Overground Walking with Feedback	Without Feedback												
Gait training with Insoles	Gait training with Conventional Shoes												
Curved Gait Training	Straight Gait Training												
Outward curved gait training	Inward curved gait training												
Gait Training on Sand	Gait Training on Firm Surface												
High-intensity Walking intervention	Step activity monitoring behavioural intervention												
High-intensity Walking intervention	High-intensity Walking intervention with Step activity monitoring behavioural intervention												
Step activity monitoring behavioural intervention	High-intensity Walking intervention with Step activity monitoring behavioural intervention												
Overground gait training	Treadmill gait training												
Treadmill training with Rehabilitation program	Overground gait training with Rehabilitation program												
Inclined treadmill training with overground walking	Regular treadmill training with overground walking												
Treadmill-based C-Mill (using gait-dependent augmented reality)	Overground walking therapy (walking-adaptability exercises with physical obstacles)												
Long-term Treadmill and Overground Walking	No Intervention												
Long-term Treadmill and Overground Walking	Short-term Treadmill and Overground Walking												
Intensive locomotor training (body weight supported treadmill with overground walking)	No training												
Treadmill training with overground gait training	Placebo program of low- intensity home exercise program with Telerehabilitation												

Error Augmentation treadmill training with Overground walking	Conventional treadmill training with Overground walking												
Error Augmentation treadmill training with Overground walking	Error Minimization treadmill training with Overground walking												
Visual performance feedback training during overground walking with conventional physical therapy	Overground walking without feedback with conventional physical therapy												
Overground gait training with Auditory feedback	Gait training												
Backward walking observational training & Conventional therapy	Landscape observational training (sham) & Conventional therapy												
Action observation of backward walking	Landscape video with Backward walking training												
Home-based cycle ergometer exercise	Home-based overground walking exercise												
Treadmill training and overground gait training	Placebo program of low- intensity home exercise program with Telerehabilitation												
Overground walking training with i-Walker robotic assistive device	Conventional overground walking training												
Gait Trainer GT I (Rehastim)	Conventional physiotherapy												
Functional electrical stimulation of Dorsiflexors and Plantar Flexors with Overground Walking program	Overground Walking program												
Conventional gait training therapy + Conductive (Petho) methods education	Conventional gait training												
Kleynen et al.	control												
Bent Knee (Prowling) Gait Training	Conventional Therapy												
Discrete-skill step training on paretic hip extension movement	control												

Cycle Ergometer Training (40 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Cycle Ergometer Training	Conventional Therapy												
Cycle Ergometer Training	Sham or No Treatment												
Cycle Ergometer	Stretching												
Interlimb Coupling Training	Conventional Therapy												
Cycle Ergometry with virtual reality	Cycle Ergometry												
Electromyography-triggered Pedalling Training	Pedalling Training												
Conventional Rehabilitation with Cycling training and biofeedback	Conventional Rehabilitation (CR)												
Brain-computer interface- controlled pedaling training	Sham brain-computer interface-controlled pedaling training												
Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer)	Conventional Care												
Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling)	Conventional Therapy												
Cycling with functional electrical stimulation	Cycling with Sham functional electrical stimulation												
Functional electrical stimulation with Cycling Ergometer and Conventional Care	Conventional Care												

High-frequency repetitive transcranial magnetic stimulation with Hesed coil during active cycling	Sham repetitive transcranial magnetic stimulation during cycling												
Repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise	Sham repetitive transcranial magnetic stimulation with Visual-Feedback Cycling Exercise												
Protein supplement with Cycle ergometer exercise	Carbohydrate supplement with Cycle ergometer exercise												
In-Bed Cycling	Usual Care												
Active Cycling with Education and Coaching	Active Cycling with Education or Passive Mobilization												
Cycle Ergometer and Treadmill Training	Conventional Therapy												
Cycle Ergometer Training	Overground Walking												
Aerobic training (Ergometer bicycle training)	Aerobic training (sliding machine)												
Progressive Resistance Training and Cycling	Sham Progressive Resistance Training and Cycling												
Aerobic cycling exercise training	Computerized cognitive training or Aerobic exercise with computerized cognitive training												
Computerized cognitive training	Aerobic exercise with computerized cognitive training												
Body weight supported treadmill with upper extremity ergometry training	Resistive leg cycling with upper extremity ergometry training												
Body weight supported treadmill with upper extremity ergometry training	body weight supported treadmill with resistive leg cycling training or body weight supported treadmill with lower extremity progressive resistive exercise												
Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training	Sham Combined aerobic and resistance training with Sham Cognitive training												
Circuit walking, balance, cycling and strength training (CBCS)	Sociocultural intervention (board games, cultural discourse and drama)												
Aerobic training on cycle ergometer	Sham training of upper extremities												
Aerobic cycling with progressive resistance training (PRT)	Sham cycling with Sham PRT												
Home-based cycle ergometer exercise	Home-based overground walking exercise												
ExoAtlet exoskeleton exercises with rehabilitation	Ortorent MOTO pedal trainer for active-passive training with rehabilitation												
Active cycling with functional electrical stimulation	Physiotherapy												
Active Leg Cycling with functional electrical stimulation (unilaterally on the paretic lower limb)	Active Leg Cycling												
Cycling induced by functional electrical stimulation with Conventional Rehabilitation	Cycling placebo functional electrical stimulation with Conventional Rehabilitation												
Leg cycling with functional electrical stimulation with interval patterns timing	Leg cycling with functional electrical stimulation with linear patterns timing												
Functional electrical stimulation with cycling	Cycling												
Cycling with functional electrical stimulation and conventional care	Conventional care												

Progressive resistance training with Cycling	Progressive resistance training with Sham cycling or Sham progressive resistance training, Cycling or Sham progressive resistance training and Sham cycling													
Progressive resistance training with Cycling	Progressive resistance training with Sham cycling													
Sham progressive resistance training with Cycling	Sham progressive resistance training with Sham cycling													

Treadmill Training (126 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Body weight supported Treadmill Training	Conventional Therapy												
Body weight supported Treadmill Training	Overground Walking												
Body weight supported Treadmill Training with Facilitation Technique	body weight supported Training with Mechanical Assistance												
Body weight supported Treadmill Training for Different Durations	Home Exercise												
Treadmill Training with Load	Treadmill Training without Load or Conventional Therapy												
Treadmill Training with Incline	Treadmill Training with Decline or Level Treadmill Training												
Treadmill Training with Mirror Therapy	Treadmill Training												
Backward Treadmill Training	Treadmill or Conventional Rehabilitation												
Treadmill Training with Orthotic Devices	Treadmill Training												
Electromechanical gait trainer therapy with Conventional rehabilitation	Body weight-supported treadmill training with Conventional rehabilitation												
Specialized task oriented locomotor training (includes using Tilt table, limb-load monitor, isokinetic device and treadmill training) with Conventional physiotherapy	Conventional physiotherapy												
Early, intensive, gait- oriented Task specific training (isokinetic device, treadmill, tilt table) with conventional hospital care	Early, intensive traditional physical therapy approach with conventional hospital care or Conventional physical therapy and conventional hospital care or 60min/d, 5d/wk, 5wks												
Baseline conventional therapy with Treadmill training with partial body weight supported and Individual physical therapy	Baseline conventional therapy with Treadmill training with partial body weight supported												
Treadmill training with Thera- band	Treadmill training												
Treadmill Training with Mirror Therapy	Treadmill Training with Sham												
Water-based aerobic exercise on a motorized aquatic treadmill with Conventional rehabilitation therapy	Aerobic Exercise (by upper and lower body ergometers) with Conventional rehabilitation therapy												
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Conventional physical therapy with treadmill training												

Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy													
Treadmill training with Virtual reality	Stepping over real objects on 10m walkway													
Gait training program (half overground walking, half treadmill training) with Hip-assist robot	Gait training program (half overground walking, half treadmill training)													
Gait training program (treadmill with overground walking) wearing a hip-assist robot	Gait training (treadmill training with over ground walking)													
Functional electrical stimulation with treadmill gait training	Sham Functional electrical stimulation with treadmill gait training													
High Frequency repetitive transcranial magnetic stimulation (5Hz) with Treadmill Training	Sham repetitive transcranial magnetic stimulation with Treadmill Training													
Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training)	15min rest with High- intensity speed-based treadmill training													
Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training)	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training)													
Body weight supported treadmill training with anodal transcranial direct current stimulation	Body weight supported treadmill training with sham transcranial direct current stimulation													
Bilateral transcranial direct current stimulation and Treadmill	Sham transcranial direct current stimulation with Treadmill													
Bilateral transcranial direct current stimulation and Treadmill	Cathodal transcranial direct current stimulation and Treadmill													
Treadmill Training	Conventional Therapy													
Treadmill Training	Overground Training													
Treadmill training with Rehabilitation program	Overground gait training with Rehabilitation program													
Body weight supported treadmill training	body weight supported treadmill training with Conventional care													
Body weight supported Treadmill Training	Treadmill Training													
Body weight supported Treadmill Training with Mobility Skills	body weight supported Treadmill Training													
Body weight supported treadmill with upper extremity ergometry training	Resistive leg cycling with upper extremity ergometry training													
Body weight supported treadmill with upper extremity ergometry training	body weight supported treadmill with resistive leg cycling training or body weight supported treadmill with lower extremity progressive resistive exercise													
Treadmill Training with Nordic Poles	Treadmill Training													
Treadmill Training with Increased Speed	Treadmill Training with Increased Incline													
Constraint Induced Movement with Home Exercise	Treadmill Training													
Treadmill Training with Foot Drop Stimulator	Foot Drop Stimulator													
Perturbation Treadmill Training	Treadmill Training													

Turning Treadmill Training	Treadmill Training												
Treadmill Training with Proprioceptive Neuromuscular Facilitation	Treadmill Training												
Body weight supported Treadmill Training	Proprioceptive Neuromuscular Facilitation												
Treadmill Training with Obstacles	Treadmill Training												
Treadmill Training on Unstable Surface	Treadmill Training												
Treadmill Training with Horizontal Force	Treadmill Training												
Treadmill Training with virtual reality	Other Training												
Treadmill-based C-Mill (using gait-dependent augmented reality)	Overground walking therapy (walking-adaptability exercises with physical obstacles)												
Treadmill Training with Visual Deprivation	Treadmill Training												
Backward treadmill with partial body weight supported	Forward treadmill with partial body weight supported treadmill												
Treadmill Training with Overground Training	Home Exercise/ no treatment												
Long-term Treadmill and Overground Walking	Short-term Treadmill and Overground Walking												
High Intensity Treadmill Training	Low Intensity Treadmill Training												
Treadmill Training	Strength Training												
Fast Speed Treadmill Training with functional electrical stimulation	Self-selected or Fast Speed Treadmill Training												
Speed Dependent Treadmill Training	Other Treadmill Training												
Structured speed- dependent treadmill training with Conventional therapy	Limited progressive treadmill training with Conventional therapy												
Body weight supported treadmill training (fast speed)	body weight supported treadmill training (slow speed) or body weight supported treadmill training (variable speed)												
Error Augmentation Treadmill Training	Treadmill Training												
Error Augmentation treadmill training with Overground walking	Error Minimization treadmill training with Overground walking												
Treadmill Training	Stretching												
Treadmill Training with Action Observation	Treadmill Training												
Task-oriented treadmill training with conventional therapy	Treadmill training with conventional therapy												
Body weight supported treadmill training (BWST) with conventional rehabilitation	Overground gait training with conventional rehabilitation												
Treadmill-based with augmented reality	Overground walking with physical obstacles												
Body weight supported treadmill training	Overground walking training												
Overground gait training with ankle mass	Overground gait training without mass or Treadmill gait training without mass												
Aerobic training (treadmill and cycle ergometer)	Conventional rehabilitation												
Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training	Sham Combined aerobic and resistance training with Sham Cognitive training												
High-Intensity Interval Training – Treadmill	Moderate-intensity Continuous Exercise - Treadmill												

High intensity (70-80% of heart rate reserve), variable stepping training on multiple surfaces (overground, treadmill, stair climbing etc)	Conventional physical therapy care												
Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training)	Sham taping with exercise training												
Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT)	Sham taping with treadmill training												
Treadmill training using insole on less affected side	Treadmill training												
Body weight support treadmill training with visual biofeedback	Body weight support treadmill training												
Treadmill training with Gait Trainer 2 Biodex biofeedback (30-45min/d) with Conventional individual exercises	Treadmill training without biofeedback with Conventional individual exercises												
Partial body-weight support treadmill training with Visual biofeedback	Partial body-weight support treadmill training												
Treadmill training with visual biofeedback and basic physiotherapy	Treadmill training with basic physiotherapy												
Dual-task gait training with treadmill	Single-task gait training with treadmill												
Dual-task (virtual reality-based UL training while walking on treadmill)	Single task treadmill walking												
Cognitive-motor dual task training while treadmill walking with Conventional rehabilitation	Single task training on Treadmill walking with Conventional rehabilitation												
Action observational training with Treadmill training	Sham action observational training with Treadmill training												
Underwater Treadmill gait training with conventional rehabilitation	Overground gait training with conventional rehabilitation												
Aquatic-based treadmill aerobic training with conventional care	Land-based aerobic exercises on cycle ergometer with conventional care												
Aquatic therapy (physical therapy exercises) with aquatic treadmill	Conventional physical therapy exercise with land-based treadmill												
Rhythmic Auditory Stimulation with Custom Physiotherapy program and Treadmill gait training	Custom physiotherapy program with Treadmill gait training												
Treadmill training with Rhythmic auditory stimulation	Treadmill training												
Treadmill training with Rhythmic auditory feedback	Treadmill training												
Inclined treadmill training with Rhythmic auditory stimulation	Treadmill training												
Treadmill training with Rhythmic auditory stimulation	Overground training with Rhythmic auditory stimulation												
Treadmill training and overground gait training	Placebo program of low- intensity home exercise program with Telerehabilitation												
Augmented reality treadmill-based gait adaptation training	Treadmill training with overground walking												
Virtual reality treadmill training-based community ambulation	Conventional rehabilitation												
Virtual reality treadmill training-based community ambulation	Community ambulation training												
Treadmill training based real- world video recording with rehabilitation	Treadmill training with rehabilitation												
Treadmill training with Virtual reality	Treadmill training												
Treadmill with optic flow with conventional physical therapy	Conventional therapy												
Treadmill with optic flow with conventional physical therapy	Treadmill with conventional physical therapy												

Treadmill training with Virtual reality and Conventional rehabilitation	Treadmill training with Conventional rehabilitation												
Treadmill training with Virtual reality and Ankle robotics	Seated training with Virtual reality and Ankle robotics												
Hybrid Assistive Limb (HAL) exoskeleton with Bodyweight supported treadmill training	Conventional Physical therapy												
Treadmill training with HEALBOT exoskeleton	Treadmill training												
Gait training with Gait Exercise Assist Robot (GEAR)	Gait training with treadmill												
Functional electrical stimulation with treadmill training	Treadmill training												
Fast speed treadmill training with functional electrical stimulation	Self-Selected Speed Treadmill Training or Fast Speed Treadmill Training												
Treadmill training with functional electrical stimulation on gluteus medius and tibialis anterior	Treadmill training												
Treadmill training with Tilt sensor functional electrical stimulation with conventional physical therapy	Treadmill training with Placebo Tilt sensor functional electrical stimulation with conventional physical therapy												
Body Weight-Supported Treadmill Training with functional electrical stimulation	Body Weight Supported Treadmill Training												
Whole body vibration with Treadmill training	Exercises on platform without vibration with Treadmill training												
High frequency repetitive transcranial magnetic stimulation with Treadmill Training	Sham repetitive transcranial magnetic stimulation with Treadmill Training												
Cerebellar transcranial direct current stimulation with split-belt treadmill training	Sham cerebellar transcranial direct current stimulation with split-belt treadmill training												
Bicephalic Transcranial direct-current stimulation with Footdrop stimulator and Treadmill gait training	Sham transcranial direct-current stimulation with Footdrop stimulator and treadmill gait training												
Backward treadmill training with botulinum toxin type A therapy	forward treadmill training with botulinum toxin type A therapy												
Treadmill walking training + conventional PT	conventional PT												
Overground gait training + visual cue feedback	Standard physiotherapy												
Speed-dependent Treadmill Training	Task-oriented Training												
Underwater treadmill walking	Overground treadmill walking												
Rhythmic auditory stimulation with treadmill training and conventional physical therapy	Neurodevelopmental treatment with conventional physical therapy												
Rhythmic auditory stimulation with treadmill training and conventional physical therapy	Treadmill training with conventional physical therapy												
Treadmill training with Virtual reality	Conventional rehabilitation												
Treadmill Training with Smartphone Application	Treadmill Training												
Body weight supported, backward and forward treadmill training	body weight supported, forward treadmill training or body weight supported, backward treadmill training												
Treadmill training with visual biofeedback and physiotherapy exercises	Treadmill training with physiotherapy exercises												
Anodal transcranial direct current stimulation with Treadmill training	Sham transcranial direct current stimulation with Treadmill training												

Aerobic training (cycle ergometer, treadmill, balance)	Conventional rehabilitation												

Physiotherapy and Exercise Programs (40 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Body Weight Shift Technique	Conventional Therapy												
Self-regulation Rehabilitation	Conventional Therapy												
Early Rehabilitation Programs	Conventional Therapy or Rehabilitation Programs Starting at Different Times Post-Stroke												
Early Conventional therapy (after 24-48 hours)	Late Conventional therapy (72-96 hours post stroke)												
Physical Therapy	No Treatment												
Custom Exercise Programs	Conventional Therapy												
Closed Chain Exercise	Open Chain Exercise or Rehabilitation												
Sling Exercise Therapy	Conventional Therapy												
Higher Intensity Training	Lower Intensity Training or Conventional Care												
Low-to-Moderate Intensity Continuous Training	Moderate Intensity Interval Training												
Low-to-Moderate Intensity Continuous Training	Reduced-Exertion High-Intensity Interval Training												
Moderate Intensity Interval Training	Reduced-Exertion High-Intensity Interval Training												
Increased Duration of Exercise	Conventional Care/Exercise												
Aerobic Exercise with Task-Specific Training	Task-Specific Training Alone												
Motivational Interviewing with Occupational Therapy	Occupational Therapy Alone												
Leisure-time Physical Activity	Nonleisure-time Physical Activity												
Agility Exercise	Stretching												
Cross-training Physiotherapy	Conventional Physiotherapy												
Aerobic and Resistance Training	Aerobic Training												
Aerobic and Resistance Training	Conventional Care												
Aerobic Exercise with Cognitive Training	Nonaerobic Exercise with Unstructured Mental Activities or Sham												
Virtual Reality Exercise Program	Customized Physiotherapy or Conventional Physiotherapy												
High-intensity variable stepping training	High-intensity forward stepping training or Low-intensity variable stepping training												
Community-based Physical Activity	No Intervention												
Community-based Exercise Program	Other Care												
Community-based Exercise Program	Upper Extremity Exercise Program												
Falls Prevention Program	Usual Care												
High-Intensity Training with Acute Intermittent Hypoxia	High-Intensity Training Alone												
Cognitive therapy with graded activity training	Cognitive therapy												
Skating Exercise	Treadmill Training												

If-Then goal setting for exercise	Goal setting												
Neurorestoration Protocol Physiotherapy	Conventional Physiotherapy												
Physio equipment	Conventional Therapy												
High-intensity Functional Exercise Program	Education												
Non-Paretic Side Training	Conventional Therapy												
Specific PT protocol (Techniques aimed to strengthen sensitivity, movement dissociation and balance. Were added based on patients functional level)	Conventional PT protocol												
Repetitive weight bearing exercises repeated 40 times	Repetitive weight bearing exercises repeated 20 times												
Range of Motion exercise program by themselves	Range of Motion exercise program with physical help												
Occupational Therapy	No Treatment												
Team Care	conventional care												

Balance Training (95 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Balance-Focused Exercise Programs	Conventional Rehabilitation												
Balance Training with Posture Changes	Balance Training												
Shoulder elevation posture change with balance training and Conventional training	Back posture change with balance training and Conventional training												
Balance Training Using SMART Balance Master	Conventional Rehabilitation												
Balance Training with Visual Biofeedback	Conventional Therapy or Balance Training												
Standing Practice	Conventional Therapy												
Perturbation Balance Trainers with Feedback	Conventional Therapy or Balance Training												
Perturbation Balance Trainers	Conventional Therapy or Balance Training												
Balance Training with Kinesthetic Ability Training Device	Conventional Rehabilitation												
Balance Training with Biofeedback	Balance Training												
Balance Training with transcutaneous electrical nerve stimulation	Balance Training with Conventional Care												
Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care	Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care												
Strength or Resistance Training with Balance Training	Conventional Therapy												
Class-Based Body Awareness Training	Home-Based Body Awareness Training												
Computer-generated interactive visual feedback balance training with Physical therapy	Mirror visual feedback balance training with Physical therapy												
Balance training with cognitive training	Balance training with balance board												
Progressive resistance with balance training and motivational session	Usual activity												

Virtual balance training (VBT) with Conservative training	Conservative training (traditional rehab techniques)												
Robot assisted gait training with Traditional balance training	Traditonal balance training												
Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy												
Task Specific Balance Training	Upper Limb Exercise												
Balance training with Visual feedback	Balance training with Verbal and tactile cues												
Non-Supportive Balance Trainers with Feedback	Conventional Therapy or Balance Training												
Balance Training with Visual Deprivation	Balance Training with Visual Cues												
Balance Training with Muscle Vibration	Conventional Rehabilitation												
Vestibular Training	Conventional Therapy												
Gaze stabilization exercises with balance exercises and neurodevelopmental treatment	gaze stabilization exercises with neurodevelopmental treatment												
Robotic Balance Training	Conventional Therapy												
Robotic balance training with conventional rehabilitation	Intensive balance training with conventional rehabilitation												
Trampoline Balance Training	Stable Surface Balance Training												
Ankle-Foot orthosis with Balance Training Shoes	Ankle-Foot Orthosis with Regular Shoes												
Balance Training with Fresnel Prism Glasses	Balance and Walking Training												
Sensory Balance Training	Robot-assisted Stair Climbing												
Sitting Balance Training with Sensory Input	Sitting Balance												
External focus on balance board task	Internal focus on balance board task												
Vestibular rehabilitation	Convectional treatment												
Perturbation Balance Training	Proprioceptive Neuromuscular Facilitation												
Vestibular Training	Virtual Reality Training												
Trunk balance training on rocker board with conventional therapy	Trunk balance training on plain surface with conventional therapy												
Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy												
Treadmill gait and balance training with Traditional gait and balance training	Traditional gait with balance training												
Perturbation treadmill training group	Non-perturbation treadmill training group												
Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training)	Sham taping with exercise training												
Rehabilitation with Balance training and Visual biofeedback	rehabilitation program												
Rehabilitation with Balance training and Visual biofeedback	rehabilitation program with lateral wedge insole												
Pro-Kin system with weight loss system (body-weight support) with balance training	Conventional balance training												
Visual feedback with Unstable surface balance training	Conventional physical therapy												

Visual feedback with Unstable surface balance training	Unstable surface balance training												
Tetrax biofeedback balance training with Conventional care	Conventional care												
Metronome training with core strengthening and general balance exercises	Core strengthening with general balance exercises												
Virtual reality balance training with Nintendo Wii with conventional physical therapy	Conventional physical therapy												
Modified PC Balance Training Gaming Platform	PC gaming with Mouse												
Wii Fit-based balance exercise with conventional rehabilitation	Conventional rehabilitation												
Virtual reality balance training with treatment	treatment												
Virtual reality-based balance training	Conventional rehabilitation												
Video Game-Based Balance Training with conventional physical therapy	Conventional physical therapy with Balance Training												
Wii-based balance training	Conventional rehabilitation												
Balance training with Balance Control Trainer	Conventional rehabilitation												
Virtual reality-based balance training	Conventional therapy												
Conventional balance training with visual balance training with Pro-kin system and Game training	Conventional balance training												
Dynamic balance training with Balance Trainer	Static balance training with a conventional standing frame												
Wii-based balance training	Progressive balance training												
3D balance exercises (3D Thera-Balance) with visual feedback	Weight shifting exercises												
Wii Fit Plus video game (Balance training)	Wii Sports video game (Upper limb training)												
Balance Training with electromyography- triggered functional electrical stimulation and General Rehabilitation	Balance Training without functional electrical stimulation with General Rehabilitation												
Standing balance exercises with functional electrical stimulation	Usual care												
Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy	Sham transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy												
Vibrosphere (balance training with whole body vibration) and conventional geriatric rehabilitation	Conventional geriatric rehabilitation												
Vestibular rehabilitation therapy + Conventional physical therapy	Conventional care												
Contemporary Bobath Concept Approach with early sitting, standing, and walking strategies with balance training	Contemporary Bobath Concept Approach												
Biofeedback Balance training (RIABLO training)	Conventional balance training												
Wobble Board Training	Conventional Physiotherapy												
Balance-Focused Exercise Programs	At-home Exercises												
Balance training with self- controlled postural control visual biofeedback	Balance training with no control over postural control visual biofeedback												
Visual Deprivation Group Balance Training Group with Conventional Therapy	Visual Feedback Balance Training Group with Conventional Therapy												

Visual cue deprivation with balance training and head control	Visual cue deprivation with Balance training													
Balance Training with Full Rest Periods	Balance Training with Short Rest Periods													
Pressure sensor-based vibrotactile biofeedback	Visual biofeedback providing posture information													
Wii Fit balance training	Tetrax biofeedback balance training													
Balance Training with Shoe Lift	Balance Training													
Structured Balance Awareness	Health Awareness Program													
Progressive Balance Training	Balance Training													
Visual Scanning Training with Task-Specific Activities	Task-Specific Activities Alone													
Foot Mobilization with Intrinsic Foor Muscles Facilitation and (Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations)	Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations													
Ankle Foot Orthosis (Joint type) with Balance Training	No Orthotic with Balance Training													
Balance training with cognitive training	Balance training													
Dual-task balance training	Single-task balance training													
Visual feedback via Mirror with Verbal feedback and Conventional treatment (static and dynamic balance training)	Visual feedback via Mirror with Conventional treatment (static and dynamic balance training)													
Isokinetic strength training with balance exercises	Conventional physiotherapy													
Wii Fit balance training	Conventional weight-shifting training													
Gaming Assisted Visual feedback for balance training with Conventional therapy	Balance training exercises with Conventional therapy													
Wii-based balance training	Control group													
Vestibular rehabilitation + conventional PT	conventional PT													
Cognitive behaviour therapy + task-oriented balance training	General health education + task-oriented balance training													
Visual-spatial training exercises using specular vision training, mirror training, and target identification while walking + Conventional rehabilitation	Trunk stabilization and weight transfer exercises + Conventional rehabilitation													

Stretching or Mobilization Exercises (56 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Mobilization Therapy or Placebo	Conventional Therapy or Placebo												
Early and Intense Mobilization	Care												
Dynamic Stretching (Tai Chi, Yoga, Pilates)	Conventional or No Therapy												
Daoyin with Conventional rehab	Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab												
Body Weight Supported Dynamic Stretching	Conventional Therapy												
Proprioceptive Neuromuscular Facilitation with virtual reality	proprioceptive neuromuscular facilitation or virtual reality Alone												

Virtual Reality (Nintendo Wii)	Proprioceptive Neuromuscular Facilitation												
Virtual Reality (Nintendo Wii)	Virtual Reality with Proprioceptive Neuromuscular Facilitation												
Robot assisted ankle stretching device (Beijing LTK Science and Technology Co., Ltd., Beijing, China)	Manual stretching by the appointed physiotherapist												
Therapeutic ultrasound with passive stretching exercise	Passive stretching exercise												
Baduanjin exercise training with Health education program	Health education program												
Chiropractic spinal adjustments + Physical Therapy	Sham chiropractic + physical therapy												
Functional Stretching	Conventional Therapy												
Manual therapy with task oriented training and home exercise program	task oriented training with home exercise program												
Sustained natural apophyseal glides with neurodevelopmental techniques	Maitland mobilization with neurodevelopmental techniques												
Joint mobilization with acupuncture	Joint mobilization												
Active Stretching	Joint mobilization with active stretching												
Mobilization With Movement	Muscle Stretching												
Self-ankle mobilization with rehabilitation	Self-ankle mobilization with 10-degree inclined board with rehabilitation												
Early Proprioceptive Neuromuscular Facilitation	late Proprioceptive Neuromuscular Facilitation												
Baduanjin Training	Conventional Exercise												
Technology-Assisted Ankle Stretcher	Stretching Board												
Isotonic muscle stretch with weight bearing	Healthy isotonic muscle stretch with weight bearing or Healthy isotonic stretch without weight bearing or Healthy isokinetic stretch												
Ankle Range of Motion Training	No Treatment												
Subtalar joint and talocrural joint mobilization with neurodevelopmental techniques	Talocrural joint only mobilization with neurodevelopmental techniques												
Peripheral Nerve Mobilization with virtual reality-Based Gait Training	Conventional Exercises												
Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT)	Sham taping with treadmill training												
Ankle Kinesio taping	No Taping												
Stretching exercise with wearing toe spreader	No Orthotic (conventional care)												
Aquatic therapy (based on proprioceptive neuromuscular facilitation)	Proprioceptive neuromuscular facilitation on the ground												
Aquatic therapy (based on proprioceptive neuromuscular facilitation)	Conventional therapy												
Robot assisted passive stretching and active movement training	At-home passive ankle stretching												
Robotic ankle stretching exercises	Conventional stretching board 2d/wk, for 3												
Whole Body Vibration (40 hz,4 mm) with Exercise (Stretching and active ROM exercise)	Sham Vibration with Exercise (Stretching and active ROM exercise)												

Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises	Sham Radial Extracorporeal Shock Wave Therapy with antispastic meds and stretching excercises												
Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy	Convetional physiotherapy												
Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy	Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy												
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with Taping and stretching and gait training												
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with stretching and gait training												
Botulinum toxin A (100U) with Taping and stretching and gait training	Botulinum toxin A (100U) with stretching and gait training												
Tai Chi Yunshou	Common Balance Rehabilitation Therapy												
Dynamic Stretching	SilverSneaker exercises vs Usual care												
Tai Chi	SilverSneakers exercises												
Proprioceptive Neuromuscular Facilitation with Electrical Stimulation	proprioceptive neuromuscular facilitation Alone												
Task-specific training with Ankle joint mobilizations	Task-specific training												
Task-specific training	Proprioceptive Neuromuscular Facilitation												
Proprioceptive neuromuscular facilitation trunk pattern with electromyography- triggered functional electrical stimulation	Proprioceptive neuromuscular facilitation trunk pattern												
Proprioceptive Neuromuscular Facilitation	Conventional Therapy												
Proprioceptive neuromuscular facilitation-Based Gait Training	Conventional Gait Training												
Performance-based training with Anklebot stretching	Manual stretching of ankle												
Tai Chi Chuan exercises	Conventional care physiotherapy												
Neurodevelopmental Bobath Concept Approach	proprioceptive neuromuscular facilitation method (proprioceptive neuromuscular facilitation)												
Botulinum toxin A (500U) with functional electrical stimulation	Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching												
Proprioceptive Neuromuscular Facilitation with Custom Exercises	Custom Exercises Alone												
Extracorporeal Shock Wave Therapy with stretching and Oral anti-spastic drugs	stretching with Oral anti-spastic drugs												
Stretching in a Supine Position	Stretching in a Seated Position												

Orthotic Devices (73 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL

Taping	no taping, sham taping, or conventional therapy												
Weight-Shift Therapy Using Shoe Insert	Conventional Treatment												
Ankle-Foot Orthosis	No Ankle-Foot Orthosis or Sham Ankle-Foot Orthosis												
Oswestry standing frame treatment	Usual treatment												
Treadmill Training with Orthotic Devices	Treadmill Training Alone												
Robot-assisted ankle-foot- orthosis (ankle-foot orthosis) with dorsiflexion assistance	Sham Ankle foot orthosis (ankle-foot orthosis) with torque impedance												
Bicephalic transcranial direct current stimulation with gait training and foot drop stimulator (Walkaide orthosis)	Sham transcranial direct current stimulation with gait training and foot drop stimulator												
Tibial nerve block through thermocoagulation with ankle-foot orthosis	Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis												
Botulinum toxin A under ultrasound guidance with ankle foot orthosis (ankle-foot orthosis) and Conventional rehabilitation	Conventional rehabilitation												
Anterior Kinesio Taping	Posterior Kinesio Taping												
Extensor Digitorum Longus Taping	Tibialis Anterior Taping												
Pelvic stability training with posterior and lateral taping	Pelvic stability training with posterior taping only												
Walking with hip abductor taping	Walking with cane at normal height												
Walking with TheraTogs	Walking with cane at normal height												
Taping With Electrical Stimulation	Electrical Stimulation or Taping Alone or No Taping												
New Body Orthosis	No Orthosis												
Shoe Insole Orthotics During Walking	Overground Walking or Conventional Therapy or Sham												
Rehabilitation with Balance training and Visual biofeedback	rehabilitation program with lateral wedge insole												
C-ankle-foot orthosis ("off the shelf" composite ankle-foot orthosis)	P-ankle-foot orthosis (custom made plastic ankle-foot orthosis)												
Ankle-Foot Orthosis with Botulinum Toxin	Botulinum Toxin												
Taping with Botulinum Toxin	Botulinum Toxin												
Early Ankle Foot Orthosis	Late Ankle Foot Orthosis												
A Comparison of Orthoses	Oil Damper ankle-foot orthosis with Gait training												
High PFR DAFO	Medium PFR DAFO or Low PFR Dynamic Ankle-Foot Orthosis (DAFO)												
Low PFR Dynamic Ankle-Foot Orthosis (DAFO)	Medium PFR DAFO												
Carbon composite ankle-foot orthosis	Posterior leaf spring ankle-foot orthosis												
Using an off-the-shelf carbon ankle-foot orthosis (C- ankle-foot orthosis)	Using a custom plastic ankle-foot orthosis (P-ankle-foot orthosis)												
5-degree lateral wedge orthotic in both shoes	8												
Anterior ankle foot orthosis	Posterior ankle foot orthosis												
Toe Spreader	Conventional Care												

Comparing Types of Canes	Ambulation therapy with cane with Conventional therapy												
Single-point cane	Quad cane												
Single-point cane	Hemi-walker												
Neuromuscular electrical stimulation Orthosis	Ankle-Foot Orthosis												
Ankle-Foot Orthosis with Balance Training Shoes	Ankle-Foot Orthosis with Regular Shoes												
Arm Sling	No Therapy												
Wearable Devices	Conventional Care or No Therapy												
Knee Orthosis with Gait Training	Gait Training Alone												
Gait training with compelled weight-shift insole device	Gait training with conventional insole												
Treadmill training with Proprioceptive neuromuscular facilitation lower-leg taping (PNFLT)	Sham taping with treadmill training												
Shoulder brace during treadmill training	conventional treadmill training												
Solid Ankle-foot orthosis, then Rocker shoes	Solid Ankle-foot orthosis, then Regular shoes												
Gait training with Insole Shoe Wedge and Sensors with Auditory feedback and Conventional rehabilitation	Conventional gait training with Conventional rehabilitation												
Rehabilitation with Balance training and Visual biofeedback	rehabilitation program												
Robot-assisted gait training (Welwalk orthosis-type robotic leg) with Conventional rehab	Conventional rehab												
Gait training with robotic leg brace	Group exercise without robotic leg brace												
Ankle foot orthosis with gait training	functional electrical stimulation with gait training												
6wk of Peroneal nerve functional electrical stimulation (WalkAide Foot-Drop Stimulator) followed by 6wk of Ankle Foot Orthosis ; (ankle-foot orthosis)	Ankle Foot Orthosis only or 12wk ankle-foot orthosis												
Odstock Dropped-foot Stimulator (peroneal nerve functional electrical stimulation)	No Intervention												
Botulinum toxin A (190- 320U) with ankle-foot orthosis	Botulinum toxin A (190- 320U)												
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with Taping and stretching and gait training												
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with stretching and gait training												
Botulinum toxin A (100U) with Taping and stretching and gait training	Botulinum toxin A (100U) with stretching and gait training												
Botulinum toxin A (75- 100U) with Kinesio Taping and home exercises	Botulinum toxin A (75- 100U) with Sham taping and home exercises												
Botulinum toxin A (100U) injection into tibialis posterior with ankle-foot adhesive taping	electromyography-guided Botulinum toxin A (190-320U) injection into several calf muscles												
Wearing an Inhibitor Hand Splint during ambulation	no treatment												
Physical Therapy Wearing Insole (unaffected side)	Physical Therapy												
Arm sling	No Treatment												
Regent Suit	Conventional Therapy												

Knee immobilizer brace	Knee immobilizer brace with Rigid taping												
Knee immobilizer brace with Foot lifter orthosis	Knee immobilizer brace with Rigid taping												
Ankle-foot orthosis-PlfS with shoe (SSh)	SSh only												
Ankle-foot orthosis with mechanical plantar flexion stops (ankle-foot orthosis-PlfS) with Rocker shoe (RSh)	ankle-foot orthosis-PlfS with shoe (SSh)												
Solid Ankle Foot Orthosis	Dynamic Ankle Foot Orthosis												
Plastic ankle foot orthosis made with polypropylene	Hybrid ankle foot orthosis made with polypropylene covered with canvas fabric												
Posterior Ankle-Foot Orthosis	Anterior Ankle-Foot Orthosis												
Gait training (with insole on non-paretic foot)	Gait training (without insole)												
Botulinum toxin A (500U) with functional electrical stimulation	Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching												
Bivalve Cast	Pressure-Relieving Ankle-Foot Orthosis vs Conventional Care												
Nighttime splint wearing with Inpatient rehabilitation	Standing on a tilt table with Inpatient rehabilitation												
Visual Biofeedback with Orthotic Devices	Sham Feedback												
Ankle treatment with biomechanical visual biofeedback (using an active sensorized ankle-foot orthosis)	Ankle treatment with an inactive sensorized ankle-foot orthosis (sham)												
Cryo-airflow therapy for calf muscle with Physical therapy and Ankle foot orthosis at night	Physical therapy with Ankle foot orthosis												

Hippotherapy (6 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Hippotherapy Training Therapy	Trunk Training Therapy												
Hippotherapy Therapy or No Treatment	Conventional Therapy or No Treatment												
Hippotherapy or Rhythm and Music-Based Therapy	No Treatment												
Hippotherapy Training	Treadmill Training												
Rhythm and Music-based therapy	No treatment												
Horse riding therapy	Wait list control												

Biofeedback (82 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Gait Training with Visual Feedback	Gait Training or Conventional Therapy												
Rehabilitation with electromyography biofeedback	Conventional Therapy												
Balance Training with Computer-based Visual Feedback	Mirror Feedback												
Cycling Training with Biofeedback	Conventional Rehabilitation												

Overground Gait Training with Auditory Feedback	Gait Training												
Strength Training with Visual Feedback	Physical Therapy												
Robot-Assisted Gait Training with Biofeedback	No Biofeedback or Conventional Biofeedback												
Knowledge of Results (Real-time visual feedback)	Knowledge of Performance (Real-time feedback with instructions on how to adjust/ direct cues)												
Continuous Auditory Feedback During Sit-to-Stand Training	No Feedback During Sit-to-stand Training												
Balance training with postural control visual biofeedback (SMART Balance master)	Conventional physical therapy with balance training												
Balance training with postural control visual biofeedback from unaffected side and physiotherapy	Stand-up task with physiotherapy												
Visual feedback with Nottingham Balance Platform training and physical therapy	Sham visual feedback with Nottingham Balance Platform training and physical therapy												
Whole-Body Tilting Postural Training (Visual feedback monitor with Trunk sensor, 8- direction body tilt and Spine balance 3D)	General Postural Training												
Balance Training with a kinaesthetic ability training (KAT) device (postural control visual biofeedback)	Conventional rehabilitation												
Balance training with force platform biofeedback and Conventional rehabilitation	Conventional rehabilitation												
Neurofeedback facilitation with motor imagery	Sham neurofeedback with motor imagery												
Bi-axial ankle-resistive strengthening muscle training with visual feedback	Ankle Physical therapy												
Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy	Sham Radial Extracorporeal Shock Wave Therapy with Prokin (visual feedback balance training) and Conventional therapy												
Treadmill Training with Visual Biofeedback	Treadmill Training												
Gait Training with Activity Feedback	Gait Training or Conventional Therapy												
Gait Training with Postural Control Visual Feedback	Gait Training or electromyography Biofeedback												
Trunk Training with Visual Biofeedback	Conventional Therapy												
Constant-force electromyography-biofeedback Tibalis anterior training with general Physiotherapy	Variable-force electromyography-biofeedback Tibalis anterior training with general Physiotherapy												
Gait training with auditory feedback caused by active weight bearing on their paralyzed foot	General gait training over the ground												
Verbal Cues and Feedback During Walking	Tactile Cues and Feedback During Walking												
Biofeedback combined with sit-to-stand training	Sit to Stand Training with physiotherapy												
Balance Training with Biofeedback	Balance Training or Conventional Therapy												
Visual feedback with Unstable surface balance training	Unstable surface balance training												
Rehabilitation with Balance training and Visual biofeedback	rehabilitation program with lateral wedge insole												
Target or Reach Visual Feedback Training	Conventional Rehabilitation												

Neurofeedback	Sham												
Electromyography Biofeedback During Single Support Phase	Stance Phase												
Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy	Sit-to-stand Training with physiotherapy												
Usual rehabilitation with Sit-to- Stand training and visual feedback	Usual rehabilitation with Arm task training												
Smartphone visual feedback for trunk control training with Conventional care	Conventional care												
Trunk postural control training with visual and auditory feedback with Conventional neurorehabilitation	Conventional neurorehabilitation												
Dynamic sitting excercises in the mediolateral and anteroposterior directions with computer visual feedback with 500 (ms) delay	Dynamic sitting excercises in the mediolateral and anteroposterior directions with computer visual feedback in real time												
Physical therapy with visual biofeedback (SMART Balance master forceplate)	Physical therapy												
Balance training with Visual feedback	Conventional rehabilitation												
Balance training with Visual feedback	Balance training with Verbal and tactile cues												
Posturographic platform biofeedback training	hospital treatment												
3D balance training using visual feedback with Conventional therapy	Conventional therapy												
Balance training with postural control visual biofeedback and conventional rehabilitation	Conventional rehabilitation												
Space balance 3D training using visual feedback program with Conventional rehabilitation	Conventional rehabilitation												
Force platform biofeedback balance training with Conventional rehabilitation	Conventional rehabilitation												
Visual Deprivation Group Balance Training Group with Conventional Therapy	Conventional Therapy												
Vestibular rehabilitation (consisted of eye-head coordination exercises, balance and ambulation exercises)	Usual Home Exercise												
Gait training with Insole Shoe Wedge and Sensors with Auditory feedback and Conventional rehabilitation	Conventional gait training with Conventional rehabilitation												
Treadmill training with Rhythmic auditory feedback	Treadmill training												
3D balance exercises (3D Thera-Balance) with visual feedback	Weight shifting exercises												
Lokomat robotic training with electromyography biofeedback and Conventional therapy	Lokomat robotic training with Commercial joint torque biofeedback and Conventional therapy												
Botulinum Toxin A injection (under ultrasound guidance) with electromyography biofeedback treatment and conventional care	Botulinum Toxin A injection (under ultrasound guidance) with conventional care												
Multimodal training: Biofeedback FES +cycling training + biofeedback platform-based balance training + conventional rehabilitation	Conventional rehabilitation												
Weight support feedback cane (WSFC) gait training + conventional care	Regular cane gait training + conventional care												
100% performance feedback and scatter plot visual feedback	No performance feedback												

Biofeedback Balance training (RIABLO training)	Conventional balance training												
Galvanic vestibular stimulation	Lokomat gait training or Physiotherapy with visual feedback												
Lokomat gait training	Physiotherapy with visual feedback												
Perceptual Feedback	Conventional Treatment												
Standing postural symmetry training with a visual and auditory biofeedback trainer with repetitive sit-to-stand training and conventional rehabilitation	Conventional rehabilitation												
Smartphone-based visual feedback trunk control training with Conventional rehabilitation	Conventional Rehabilitation												
Trunk stabilization exercises with audiovisual biofeedback (Pressure biofeedback unit)	Trunk stabilization exercises												
Balance training with postural control visual biofeedback (SMART Balance master)	Conventional rehabilitation												
Gaming Assisted Visual feedback for balance training with Conventional therapy	Balance training exercises with Conventional therapy												
Balance training using Biodex stability system with visual biofeedback	Balance training												
Balance Platform Training with Audio-visual Feedback with Rehabilitation program	Rehabilitation program with postural training with physiotherapy												
Balance training with postural control visual biofeedback	Conventional physiotherapy												
Balance training with self- controlled postural control visual biofeedback	Balance training												
Balance training with self- controlled postural control visual biofeedback	Balance training with no control over postural control visual biofeedback												
Visual Deprivation Group Balance Training Group with Conventional Therapy	Visual Feedback Balance Training Group with Conventional Therapy												
Pressure sensor-based vibrotactile biofeedback	Standing without biofeedback												
Pressure sensor-based vibrotactile biofeedback	Visual biofeedback providing posture information												
Wii Fit balance training	Conventional weight-shifting training												
Wii Fit balance training	Tetrax biofeedback balance training												
Rehabilitation with Balance training and Visual biofeedback	rehabilitation program												
Visual feedback via Mirror with Verbal feedback and Conventional treatment (static and dynamic balance training)	Visual feedback via Mirror with Conventional treatment (static and dynamic balance training)												
Galvanic vestibular stimulation	Gait training (Lokomat) or Physiotherapy with visual feedback												
Gait training (Lokomat)	Physiotherapy with visual feedback												
Gait training with functional electrical stimulation	care												
EMG biofeedback from the affected-side soleus muscle (EMG)	Physical therapy (PT)												
Visual Biofeedback with Orthotic Devices	Sham Feedback												
Ankle treatment with biomechanical visual biofeedback (using an active sensorized ankle-foot orthosis)	Ankle treatment with an inactive sensorized ankle-foot orthosis (sham)												

Dual-Task Training (16 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Cognitive Dual Motor Task	Conventional Therapy or No Treatment												
Dual Task	Single Task Training or Control												
Dual Cognitive-Motor Task	Balance Training												
High-intensity multiplanar trunk training with dual-task training and conventional rehabilitation	Trunk training with conventional rehabilitation												
Dual-Task and Resistance Exercise	Aerobic and Resistance Exercise												
Dual-task training with variable priority instructional sets	Dual-task training with fixed priority instructional sets												
Cognitive Task	Motor Task vs No Task in Various Settings												
Cognitive Therapeutic Exercise Combined with Goal-Directed Training	Goal-Directed Training Alone												
Cognitive Training	Conventional Therapy												
Dual-Task Training with Motor Imagery	Dual-Task Training Alone												
Dual-task balance/mobility	Upper limb exercise												
Aquatic-based Dual-task Motor Training	Land-based Dual-task Motor Training												
Problem-Oriented Willed-Movement Therapy	Conventional Treatment												
Motor dual task training with Conventional care	Cognitive dual task training with Conventional care or Motor imagery and Conventional care												
Dual-Task Training	Vestibular Rehabilitation												
Aquatic therapy (Dual-task training with upper extremity tasks)	Neurodevelopmental techniques												

Mental Practice (25 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Gait Training with Motor Imagery or Mental Practice	Gait Training												
Neurofeedback Facilitation with Motor Imagery	Sham												
Mental Practice	Muscle Relaxation												
Mental Imagery	Conventional Training or Sham												
Motor Imagery with Virtual Reality	Virtual Reality Alone												
Task-Specific Training with Mental Practice	Task-Specific Training												
Task-Specific Training with Mental Practice	Conventional Training or No Treatment												
Proprioception Training with Motor Imagery	Proprioception Training												
Action Observation	Motor Imagery vs Conventional Therapy												
Circuit Training with Mental Practice	Circuit Training with Education												
Visual Locomotor Imagery Training	Kinesthetic Locomotor Imagery Training												

Visual Locomotor Imagery Training	Visual Locomotor Training with Auditory Step Rhythm												
Kinesthetic Locomotor Imagery Training	Visual Locomotor Training with Auditory Step Rhythm												
Kinesthetic Locomotor Imagery Training	Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm												
Visual Locomotor Training with Auditory Step Rhythm	Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm												
Body Awareness Therapy	Continuing Usual Daily Activities												
Mental Practice	Cognitive Training												
Task-oriented circuit class training with Motor imagery	rehabilitation (Bobath)												
Gait training with guided motor imagery and conventional exercises	Gait training with conventional exercises or 30min/d, 3d/wk, 4wks gait training												
Dual-task training with motor imagery	Dual-task training												
Action observation training with physical training	physical training												
Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm	the other study arms												
Modified sit-to-stand training with mental practice with conventional therapy	Conventional Treatment												
Motor dual task training with Conventional care	Cognitive dual task training with Conventional care or Motor imagery and Conventional care												
Cognitive Sensory Motor Training	Conventional Therapy												

Action Observation (9 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Backward Walking Action Observation	Sham or Conventional therapy												
Action Observation Physical Training	Sham Action Observation Training												
Action Observation Training with Gait Training	Gait Training												
Action Observation with Treadmill Training	Treadmill Training												
Action Observation with functional electrical stimulation and Gait Training	Gait Training and functional electrical stimulation												
Action observational training with Treadmill training	Sham action observational training with Treadmill training												
Action observation training with physical training	physical training												
Action observation training with Rhythmic auditory stimulation and physical therapy	Action observation with physical therapy												
Functional Action Observation	General Action Observation												

Mirror Therapy (24 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Mirror Therapy	Conventional Therapy or Sham Therapy												

Intensive Mirror Therapy	Mirror Therapy												
Treadmill Training Combined with Mirror Therapy	Treadmill Training												
Mirror Therapy with Stimulation	Mirror Therapy or Task Oriented Training												
Mirror therapy	Mirror therapy with Mesh glove (afferent stimulation)												
Mirror Therapy combined with neuromuscular electrical stimulation	Mirror Therapy with Sham neuromuscular electrical stimulation or Conventional Therapy												
Conventional rehabilitation with mirror therapy and neuromuscular electrical stimulation	conventional rehabilitation with mirror therapy												
Mirror Therapy combined with functional electrical stimulation	Conventional Therapy												
Mirror Therapy with Virtual Reality	Conventional therapy												
Treadmill Training with Mirror Therapy	Treadmill Training with Sham												
Virtual reality therapy and mirror therapy (MT) exercises	lower extremity rehabilitation												
Mirror therapy with Functional electrical stimulation	Conventional therapy												
Mirror Therapy with Task Oriented Training	Task Oriented Training												
Mirror Therapy with repetitive transcranial magnetic stimulation	Mirror Therapy with Sham Stimulation												
Task-oriented training with mirror therapy	Task oriented training												
Home based Isometric Unilateral Strength Training with Mirror Therapy	Home based Isometric Unilateral Strength Training												
Home rehabilitation, then Clinic rehabilitation	Clinic rehabilitation, then home rehabilitation												
Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy	Conventional therapy												
Electrical stimulation with mirror therapy	Sham electrical stimulation with sham mirror therapy												
Low frequency (1Hz) Repetitive Transcranial Magnetic Stimulation with mirror therapy	Sham repetitive transcranial magnetic stimulation with mirror therapy												
Camera-Based Mirror Therapy	Conventional Therapy												
Mirror Therapy with Verbal Feedback	Mirror Therapy Alone												
At home Mirror therapy + Usual care	At home Lower limb exercises + Usual care												
Conventional rehabilitation with mirror therapy and neuromuscular electrical stimulation	Conventional rehabilitation with Sham mirror therapy												

Aquatic Therapy (11 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Aquatic Therapy	Conventional Therapy												
Aquatic Treadmill Walking or Aerobic Therapy	Overground or Treadmill Walking or Cycle Ergometer												
Aquatic Therapy	Land-Based Upper Extremity Exercises												
Aquatic Ai Chi Therapy with Dry Land Therapy	Aquatic Ai Chi Therapy												

Dual-Task Aquatic Training	Neurodevelopmental Techniques or Land-Based Dual Motor Task												
Aquatic Therapy with Strength Training	Aquatic Therapy												
Anti gravity treadmill	Conventional therapy												
Waterjet resistance aquatic treadmill training + conventional PT	control												
Aqua therapy in shallow water	Aqua therapy in deep water												
Sequential Preparatory Approach Aquatic Therapy	Aquatic Therapy												
Land-based and aquatic trunk exercises with conventional physiotherapy	Conventional physiotherapy or 60min/d, 5d/wk, 4wks conventional physiotherapy												

Strength and Resistance Training (48 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Strength or Resistance Training	Conventional Therapy or Educational Classes												
Strength and Resistance Training Modalities	Limb overloading resistance training												
Strength Training with Visual Feedback	Physical Therapy												
Resistance Training with Balance Training	Conventional Therapy												
Early conventional physical therapy with intensive strength exercises	Conventional physiotherapy												
Bi-axial ankle-resistive strengthening muscle training with visual feedback	Ankle Physical therapy												
Task oriented circuit gait training	Strength training of lower extremities												
Functional strength training - upper limb	Functional strength training - lower limb												
Rehabilitation program with leg training	Rehabilitation program with Arm training												
Strength or Resistance Training	Stretching or Relaxation												
Aerobic and Resistance Training	Conventional Therapy or Aerobic Training												
Aerobic training	Progressive resistance training												
Eccentric resistance training with Gait training	Concentric resistance training with Gait training												
Strength and Resistance Training Intensity	High intensity resistance training (HIRT)												
Low intensity walking and resistance training program	High intensity walking and resistance training program												
Home based Isometric Unilateral Strength Training with Mirror Therapy	Home based Isometric Unilateral Strength Training												
Resistance Training with and without repetitive transcranial magnetic stimulation	Resistance Training or repetitive transcranial magnetic stimulation Alone												
Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation	Ankle Strengthening												
Muscle Strength Training to Paralytic Muscles	Muscle Strength Training to Non-paralytic Muscles												
Core strengthening exercises with Conventional rehab	Conventional rehab												
Task-oriented progressive resistance strength training	No treatment												
Task oriented circuit gait training	Educational session on stroke management												

Task Oriented circuit LE strength training with physiotherapy	Conventional physiotherapy												
Aerobic training on cycle ergometer	Sham training of upper extremities												
Aerobic cycling with progressive resistance training (PRT)	Sham cycling with Sham PRT												
Aerobic training (over ground walking) with Resistance training	Aerobic Training												
Individualized cardio rehabilitation (aerobic & resistance training) with Conventional stroke rehab	Conventional Stroke Rehabilitation												
Aerobic Training (fast walking and walking up-stairs) with Resistance Training	Conventional care												
Aerobic training (Stationary treadmill or bicycle ergometer) with resistance training and cognitive training	Sham Combined aerobic and resistance training with Sham Cognitive training												
Circuit walking, balance, cycling and strength training (CBCS)	Sociocultural intervention (board games, cultural discourse and drama)												
Non-elastic taping with Exercise training (progressive resistance exercise, balance training and treadmill training)	Sham taping with exercise training												
Dual Task (Consisting aerobic and resistance exercises while performing cognitive task)	Aerobic and Resistance Exercises, without Performing Cognitive Task												
Aquatic training with under water strength training	Aquatic training												
Metronome training with core strengthening and general balance exercises	Core strengthening with general balance exercises												
Ankle strengthening training with brain-computer interface-based functional electrical stimulation on TA	Ankle strengthening training with functional electrical stimulation on TA												
Ankle Strengthening	repetitive transcranial magnetic stimulation												
120g Nutritional supplement (Reha-Time Jelly BCAA enriched nutritional supplement) with resistance exercise training program	Resistance training exercise program												
Acupuncture with trunk strengthening training and conventional rehab	Conventional rehab with trunk strengthening training												
Lower limb resistance training with Abdominal draw-in maneuver (abdominal drawing-in maneuver) and Conventional tailored physical therapy	lower limb exercise with abdominal drawing-in maneuver and Conventional tailored physical therapy												
Isokinetic strength training with balance exercises	Conventional physiotherapy												
Foot Mobilization with Intrinsic Foor Muscles Facilitation and (Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations)	Strength and Resistance training including proprioceptive neuromuscular facilitation, Gait training and Balance training through Pertubations												
Resistance-based, reciprocal, affected leg locomotor training protocol using the NuStep apparatus	Home exercise program												
Progressive resistive training with closed-kinetic chain	No training												
Progressive resistance training with Cycling	Progressive resistance training with Sham cycling or Sham progressive resistance training, Cycling or Sham progressive resistance training and Sham cycling												

Progressive resistance training with Cycling	Progressive resistance training with Sham cycling												
Sham progressive resistance training with Cycling	Sham progressive resistance training with Sham cycling												
Extracorpeal shockwave therapy	conventional rehab												
Extracorpeal shockwave therapy	extracorporeal shockwave therapy with Isokinetic strength training												

Rhythmic Auditory Stimulation (16 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Overground Gait Training with Rhythmic Auditory Stimulation	Overground Gait Training												
Auditory Stimulation with Robot Training	Virtual Reality with Robot Training or Conventional Training												
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy												
Rhythmic Auditory Stimulation	Visual Cueing or Conventional Treatment												
Treadmill Training with Rhythmic Auditory Stimulation	Treadmill Training												
Physical Therapy with Rhythmic Auditory Feedback	Physical Therapy or Conventional Therapy												
Treadmill Training with Rhythmic Auditory Stimulation	Overground Gait with Rhythmic Auditory Stimulation												
Visual Locomotor Imagery Training	Kinesthetic Locomotor Imagery Training												
Visual Locomotor Imagery Training	Visual Locomotor Training with Auditory Step Rhythm												
Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm	the other study arms												
Kinesthetic Locomotor Imagery Training	Visual Locomotor Training with Auditory Step Rhythm												
Kinesthetic Locomotor Imagery Training	Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm												
Visual Locomotor Training with Auditory Step Rhythm	Kinesthetic Locomotor Imagery Training with Auditory Step Rhythm												
Rhythmic auditory stimulation with treadmill training and conventional physical therapy	Treadmill training with conventional physical therapy												
Action observation training with Rhythmic auditory stimulation and physical therapy	Action observation with physical therapy												
Music-movement therapy (MMT)	Conventional care												

Respiratory Training and Devices (6 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Respiratory Muscle Training	Conventional Rehabilitation or Sham Respiratory Muscle Training												
Continuous Positive Airway Pressure	Conventional Rehabilitation												

4 week inspiratory muscle training	8 week inspiratory muscle training												
Respiratory Muscle Training	Cycle Ergometer Training												
Inspiratory muscle training (IMT)	Conventional rehabilitation												
Respiratory Training	Conventional Rehabilitation with Liuzijue Qigong												

Home-Based and Caregiver-Mediated Exercise Programs (23 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Home-Based Physiotherapy and Exercise Programs	Conventional Therapy or No Therapy												
Caregiver-Mediated Programs	Conventional Care												
Nursing Mediated Program	Conventional Care												
Home-based nurse guided Telerehabilitation Exercise Program	Conventional Care												
BASNEF model motivational training with home-based rehabilitation	Conventional Care												
Caregiver-mediated exercise program with e-health support with telerehabilitation	Conventional therapy												
Caregiver-mediated iPad exercise program with FitBit activity monitor (real-time feedback)	Usual care												
Active dual-hemispheric transcranial direct current stimulation with Home-based exercise	Sham transcranial direct current stimulation with Home-based exercise												
Programmed Nursing Intervention (Including health education, personalized functional exercise plans, restoration function training)	routine rehabilitation training												
Home rehabilitation, then Clinic rehabilitation	Clinic rehabilitation, then home rehabilitation												
Home-based Oculomotor/Gaze Stability Exercises	Conventional Rehabilitation												
Home-based cycle ergometer exercise	Home-based overground walking exercise												
Early Discharged At-Home Supported Training	Conventional Post-Discharge Rehabilitation												
Specialist Community Rehabilitation	Conventional Rehabilitation												
Home-based isometric unilateral strength training with mirror therapy	Home-based isometric unilateral strength training												
Nurse-organized, family caregiver delivered rehabilitation (supported by a custom- designed smartphone application)	Usual care												
Augmented reality with home based exercise program	Home based exercise program												
Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy	Botulinum Toxin A Injection												
Custom Occupational therapy with Caregiver training workshop	Usual care alone												
Treadmill training with load (5% of body weight) on the nonparetic limb with home-based exercises	Treadmill training without load with home-based exercises												
Outpatient Clinic Care Follow-up	Conventional Control												
Home based physical activity and walking training program	Conventional care												

Rapid rehabilitation nursing with continuous nursing after discharge	Routine nursing												

Telerehabilitation and Technology-Based Home Exercise Programs (8 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Home Based Therapy Using Technology and Telerehabilitation	Conventional Therapy or No Therapy												
Telerehabilitation Physiotherapy Combined with electromyography-neuromuscular electrical stimulation	Conventional Therapy Combined with electromyography-neuromuscular electrical stimulation												
Caregiver-Mediated Programs using Telerehabilitation or Technology	Conventional Care												
Telerehabilitation Computerized Complex Repetitive Ankle Movement Training	Simple Ankle Movement Training												
Video-Based Home Exercise Training	Paper-Based Home Exercise Training												
Virtual reality-based telerehabilitation in Home with conventional physical therapy	Virtual reality-based rehabilitation in clinic with conventional physical therapy												
Smart-watch feedback on daily activity level	local routine treatment												
Home based Multimodal rehabilitation program by mHealth app	Conventional care												

Virtual Reality (48 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Virtual Reality	Conventional Therapy or No Treatment												
Virtual Reality Exercise Program	Exercise Program												
Virtual Reality with Treadmill Training	Overground Gait Training												
Virtual Reality Robotic Training	Robotic Training, Auditory Stimulation, and Conventional Therapy												
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy												
Virtual Reality with Other Modalities	Task-specific training												
Virtual Reality (Nintendo Wii)	Virtual Reality with Proprioceptive Neuromuscular Facilitation												
Brain-Computer Interface Controlled Training	Sham												
Task-oriented training with Virtual reality training	Task-oriented training												
Speed-Interactive Pedaling Training with Virtual Reality	Pedaling Training												
Virtual Reality	Proprioceptive Neuromuscular Facilitation												
Motor imagery with virtual reality training	virtual reality training with Conventional therapy												
Virtual reality therapy and mirror therapy (MT) exercises	lower extremity rehabilitation												

Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Conventional physical therapy with treadmill training													
Repetitive transcranial magnetic stimulation with Augmented reality gait adaptive training	Augmented reality gait adaptive training													
Game-based constraint-induced movement therapy with Traditional physical therapy	General game-based training with Traditional physical therapy													
Virtual Reality	Balance Training													
Virtual Reality with Treadmill Training	Conventional Therapy or Treadmill Training													
Virtual reality treadmill training-based community ambulation	Community ambulation training													
Treadmill with optic flow with conventional physical therapy	Treadmill with conventional physical therapy													
Virtual Reality Robotic Training	Robotic Training and Conventional Therapy													
Virtual Reality Training	Strength and Resistance Training													
Sit-to-stand training with visual feedback with Wii Balance Board and physiotherapy	Sit-to-stand Training with physiotherapy													
Treadmill-based with augmented reality	Overground walking with physical obstacles													
Selfpaced treadmill walking in virtual reality environment	Self Placed Overground Platform walking													
Treadmill-based C-Mill (using gait-dependent augmented reality)	Overground walking therapy (walking-adaptability exercises with physical obstacles)													
Virtual walking training (virtual reality) with rehabilitation program	Treadmill gait training with rehabilitation													
Customized Physiotherapy plan using interactive Motion Capture Rehabilitation (virtual reality- based)	Customized Physiotherapy plan													
Peripheral nerve mobilization with virtual reality-based gait training	Conventional exercises													
Dual-task (virtual reality-based UL training while walking on treadmill)	Single task treadmill walking													
Virtual reality with cognitive load with conventional rehabilitation	Treadmill walking with virtual environment with conventional rehabilitation													
Telerehabilitation using a Kinect camera-based interactive telerehabilitation system	Conventional physiotherapy													
Lokomat endurance video games	Conventional Physiotherapy													
Virtual reality augmented robot-assisted gait training with conventional care	Robot-assisted gait training with conventional care													
Treadmill training with Virtual reality and Ankle robotics	Seated training with Virtual reality and Ankle robotics													
Xbox training during anodal transcranial direct current stimulation stimulation to cerebellum	Sham transcranial direct current stimulation with xbox training													
Xbox training during anodal transcranial direct current stimulation stimulation to cerebellum	Xbox training during nodal transcranial direct current stimulation stimulation to motor cortex													
Anodal Cerebellar transcranial direct current stimulation with Xbox Kinect games ; E2 Anodal M1 transcranial direct current stimulation and Xbox Kinect games	Sham Stimulation Group with Xbox Kinect games													

Anodal Cerebellar transcranial direct current stimulation with Xbox Kinect games ; E2 Anodal M1 transcranial direct current stimulation and Xbox Kinect games	the other study arms												
Robotic-assisted gait training (Lokomat-Pro) with virtual reality	Robotic-assisted gait training (Lokomat-Nanos)												
Wii Fit balance training	Tetrax biofeedback balance training												
Wii Fit balance training	Conventional weight-shifting training												
Cognitive motor exergaming training	Conventional training (stretching, strengthening, balance and endurance training)												
Virtual Reality Training	Treadmill Training												
Self paced treadmill walking in virtual reality environment	Fixed speed treadmill walking in virtual reality environment												
Wii Balance Intervention	Conventional Balance Intervention												
Telerehabilitation video games	Conventional rehab												
Group Video game therapy	Conventional care												

Electromechanical and Robotic Devices (97 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Robot Assisted Gait Training	Conventional Therapy and Overground Gait Training												
Gait Trainer GT I (Rehastim)	Overground gait training												
End-Effector Gait Training	Body Weight Supported Treadmill												
Electromechanical gait trainer therapy with Conventional rehabilitation	Body weight-supported treadmill training with Conventional rehabilitation												
Exoskeleton Systems	Conventional Therapy or Overground Gait Training												
Robot Assisted Gait Training (Lokomat) with Conventional Therapy	Robot Assisted Gait Training (Lokomat)												
Exoskeleton Systems	Treadmill Training												
Exoskeleton Gait Training	Functional Task-Specific Training												
Exoskeleton Systems Administration Method	Therapist controlled robot-assisted gait training												
Exoskeleton Portable Devices	Overground Gait Training or Stretching vs Sham Ankle Foot Orthosis												
Exoskeleton Portable Devices	Stretching												
Exoskeleton Portable Devices with Ankle Foot Orthosis	Sham Ankle Foot Orthosis												
Robotic-Assisted Gait Training and Restraint	Robot-assisted (Lokomat) walking training with arm fixation with conventional care												
Robotics Combined with Virtual Reality	Robotics, Robotics Combined with Auditory Stimulation or Conventional Training												
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Auditory stimulation with robot-assisted gait training (Treadmill) and conventional physical therapy												

Assist-as-needed robot- assisted gait training for unaffected limb with fully-assisted robot-assisted training for affected limb	Assist-as-needed robot- assisted gait training for affected limb with fully-assisted robot- assisted training for unaffected limb													
Robotic Verticalization with functional electrical stimulation	Conventional therapy													
Robot-Assisted Gait Training with Visuomotor feedback	Robot-Assisted Gait Training													
Robotics with Treadmill Training and Virtual Reality	Seated Training													
Ankle robot training low frequency, low intensity	ankle robot training high frequency, low intensity or ankle robot training low frequency, high intensity or ankle robot training high frequency, high intensity													
Robot-Guided Ankle Proprioceptive Training with Thermal Stimulation	Conventional Therapy													
Robot-Assisted Gait Training	Upper Limb Therapy													
Robot-Assisted Gait Training with Balance Training	Balance Training Alone													
Robot-Assisted Gait Training	Home-Based Exercise Program													
Trunk stability robot training (3DBT-33) with conventional physical therapy	Conventional Physical Therapy													
Daoyin with Conventional rehab	Conventional rehab													
Daoyin with Conventional rehab	Daoyin with Lower Limb Robot, Conventional rehab or Lower Limb Robot and Conventional rehab													
Robot-assisted ankle-foot- orthosis (ankle-foot orthosis) with dorsiflexion assistance	Sham Ankle foot orthosis (ankle-foot orthosis) with torque impedance													
Virtual reality with robot- assisted gait training (Treadmill) and conventional physical therapy	Conventional physical therapy with treadmill training													
Brain-computer interface- controlled training robot with Conventional Physiotherapy	Sham brain-computer interface-controlled training robot with Conventional Physiotherapy													
Brain-computer interface- operated lower limb rehabilitation robot	Sham (Lower limb pedal training without image, video, sound hint)													
Dynamic tilt table with robotic leg movement with functional electrical stimulation	dynamic tilt table with robotic leg movement													
Robotic verticalization (ERIGO tilt table) with functional electrical stimulation and dynamic foot support	Physiotherapy-assisted verticalization (simple tilt-table)													
High definition transcranial direct current stimulation (dual) with Robot assisted gait training	Sham High definition transcranial direct current stimulation with Robot assisted gait training													
Robot-assisted gait training and anodal transcranial direct current stimulation	Robot-assisted gait training and sham stimulation													
Interactive Dynamic Scalp Acupuncture with lower-limb robot training (SA & LLRT simultaneously) and Basic Treatment	Scalp Acupuncture with Basic Treatment													
Interactive Dynamic Scalp Acupuncture with lower-limb robot training (SA & LLRT simultaneously) and Basic Treatment	Scalp Acupuncture with lower-limb robot training (LLRT, SA separately) and Basic Treatment													
2x Lokomat gait training + 1x Conventional PT	2x Conventional PT + 1x Lokomat gait training													
Gait trainer device (REHA-STIM)	Conventional rehabilitation (Bobath)													

Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2												
Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation	Gait Trainer GT II (Rehastim) with Regular rehabilitation												
Robot Assisted Gait Training	Balance Training												
Electromechanical Gait Training	Conventional Treatment or No Treatment												
Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy	Electromechanical gait trainer with Conventional physical therapy												
Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy	Electromechanical gait trainer with Conventional therapy												
ExoAtlet exoskeleton exercises with rehabilitation	Ortorent MOTO pedal trainer for active-passive training with rehabilitation												
Resistance load Robotic gait system training	Assistance Robotic gait system training												
Therapist-assisted locomotor training	Robotic-assisted locomotor training												
30% weight robot gait training with general physical therapy	50% weight robot gait training with general physical therapy												
30% weight robot gait training with general physical therapy	70% weight robot gait training with general physical therapy												
50% weight robot gait training with general physical therapy	70% weight robot gait training with general physical therapy												
Robot-assisted training with Power-assisted ankle robot with Conventional training	Robot-assisted training with Swing-controlled ankle robot with Conventional training												
Gait training with Gait Exercise Assist Robot (GEAR)	Gait training with treadmill												
Robotic-assisted Stretching	Conventional Therapy												
Regent Suit with Neuromotor rehabilitation	Neuromotor rehabilitation												
Robot-assisted Task Specific Training	Task Specific Walking												
Robotic gait training with Exoskeleton ExoAthlet with Conventional physiotherapy	Robotic gait training with Lokomat Free-D with Conventional physiotherapy												
Robot-Assisted Gait Training with Robotic Balance Platform	Robot-Assisted Gait Training Alone												
Robotic balance training with conventional rehabilitation	Conventional training												
Robotic balance training with conventional rehabilitation	Intensive balance training with conventional rehabilitation												
Robot-assisted balance exercises	Conventional care												
Robot-assisted stair climbing training (G-EO System)	Sensory integration balance training												
Robotic ankle stretching exercises	Conventional stretching board												
Lokomat robotic training with electromyography biofeedback and Conventional therapy	Lokomat robotic training with Commercial joint torque biofeedback and Conventional therapy												
Virtual reality augmented robot-assisted gait training with conventional care	Robot-assisted gait training with conventional care												
Robot-assisted gait training with Virtual reality	Robot-assisted gait training												
Virtual reality robotic training (computer)	Robotic training												

Treadmill training with Virtual reality and Ankle robotics	Seated training with Virtual reality and Ankle robotics													
Robot-assisted (Lokomat) gait training with functional electrical stimulation on the ankle dorsiflexor of affected side	Robot-assisted (Lokomat) gait training													
Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy	Gait training with Conventional physical therapy													
Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy	Overground gait training with Conventional therapy													
Robot-assisted gait training and anodal transcranial direct current stimulation over the leg motor cortex area	Robot-assisted gait training only													
Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2													
Anodal transcranial direct current stimulation with Robot- assisted gait training	Sham transcranial direct current stimulation with Robot- assisted gait training													
Anodal transcranial direct current stimulation with Robot- assisted gait training	Gait training													
Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training	Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training													
Robotic Gait Training (Lokomat robotic exoskeleton) with Botulinum toxin injection	Botulinum toxin injection with Conventional physiotherapy													
Botulinum toxin A with Robot assisted Gait Training (RoboGait) and Conventional Physiotherapy	Botulinum toxin A with Conventional Physiotherapy or 90min physical therapy 1session/d, 5d/wk, for 3wks													
Botox (250U) With Robot- Assisted Gait Therapy	Botox Alone													
Acupuncture with Gait rehab robot training (AiWalker-I) and Conventional rehab	Acupuncture with Conventional rehab													
Fast rhythmic robot-assisted locomotor training on body-weight supported treadmill	control													
Progressive reducing assistance force during robot-assisted gait training + conventional PT	Full assistance force during robot-assisted gait training + conventional PT													
Robot-assisted gait training (Lokomat) with Virtual reality	Robot-assisted gait training (Lokomat)													
Galvanic vestibular stimulation	Gait training (Lokomat) or Physiotherapy with visual feedback													
Gait training (Lokomat)	Physiotherapy with visual feedback													
Robot-assisted Trunk Training	Conventional Therapy													
Vibration on sole of foot	Contact on Sole of Foot with No Vibration													
Robot-assisted trunk control training with Conventional trunk stabilization exercise	Conventional trunk stabilization exercise with stretching exercise													
Galvanic vestibular stimulation	Lokomat gait training or Physiotherapy with visual feedback													

Lokomat gait training	Physiotherapy with visual feedback												
Ankle-knee-hip Interlimb coordinated humanoid robot + Conventional Physical therapy	Gait training + Conventional PT												
Healbot T (Exoskeleton) with pelvic motion on	Healbot T (Exoskeleton) with pelvic motion off												
Gait Training with Gait Exercise Assist Robot (GEAR)	Overground Gait Training												
Haemorrhagic Stroke Erigo Robotic Tilt Table	Haemorrhagic Stroke Conventional Care or Ischemic Stroke Conventional Care												
Robotic tilt table (Erigo) therapy	Conventional physiotherapy												
Robotic Tilt table with Upper extremity exercises	Conventional therapy												
Robot-Assisted Gait Training	Physiotherapy												

Functional Electrical Stimulation (53 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Functional electrical stimulation Therapy or Sham Stimulation	Conventional Therapy or Sham Stimulation												
Functional electrical stimulation Combined with Gait Training	Gait Training or Conventional Therapy												
Cycling with functional electrical stimulation	Cycling with or without Sham functional electrical stimulation or Conventional Therapy												
Treadmill Training with functional electrical stimulation	Treadmill Training with or without Sham functional electrical stimulation												
Functional electrical stimulation with Tilt Table	Conventional Therapy or Simple Tilt Table												
Functional electrical stimulation Muscle Stimulation	Electrical Muscle Stimulation												
Four-Channel functional electrical stimulation	Dual-Channel functional electrical stimulation vs Sham												
Four-channel functional electrical stimulation with physiotherapy	Dual-channel functional electrical stimulation with physiotherapy												
Four-channel functional electrical stimulation with Conventional therapy	Dual-channel functional electrical stimulation with Conventional therapy												
Mirror Therapy with Functional Electrical Stimulation	Conventional Therapy												
Transcranial direct current stimulation with conventional therapy	Functional electrical stimulation with conventional therapy												
Peroneal Nerve functional electrical stimulation (Foot-drop Stimulator)	Ankle-Foot Orthosis												
Peroneal Nerve functional electrical stimulation (Foot-drop Stimulator)	Conventional Therapy or Gait Training												
Peroneal Nerve Stimulation	Sham Stimulation or Conventional Therapy												
Mirror feedback with functional electrical stimulation	Conventional rehab with functional electrical stimulation												
Mirror therapy with Functional electrical stimulation	Conventional therapy or 50 min, 4d/wk, for 2wks CT 1wk washout												
Robotic verticalization with functional electrical stimulation and dynamic foot support	Physiotherapy-assisted verticalization (simple tilt-table)												
Circuit Training (NESS L300 & Motomed Viva 2 functional electrical stimulation with Cycling & Brain trainer)	Conventional Care												

Contralaterally controlled functional electrical stimulation with rehab	Neuromuscular electrical stimulaion (neuromuscular electrical stimulation) with rehab												
Bicephalic transcranial direct current stimulation with gait training and foot drop stimulator (Walkaide orthosis)	Sham transcranial direct current stimulation with gait training and foot drop stimulator												
Botulinum toxin type A injection with functional electrical stimulation and Conventional physiotherapy	Conventional physiotherapy												
Rehabilitation with functional electrical stimulation	rehabilitation with Placebo stimulation												
Interval Cycling with functional electrical stimulation	Linear Cycling with functional electrical stimulation												
Robot-assisted Gait Training with functional electrical stimulation	Gait Training or Robot-assisted Gait Training												
Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy	Electromechanical gait trainer with Conventional physical therapy												
Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy	Electromechanical gait trainer with Conventional therapy												
Balance Training with functional electrical stimulation	Balance Training or Conventional Care												
Ankle Training with brain-computer interface-based functional electrical stimulation	Ankle Training with functional electrical stimulation												
Functional electrical stimulation with Motor Training on Rocker Board	Conventional Exercises												
Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy	Electromyography triggered neuromuscular electrical stimulation training (single electrical stimulation) with conventional physiotherapy												
Faradic Electrical Stimulation	Russian Electrical Stimulation												
Faradic electrical stimulation with Task-oriented exercise	Russian electrical stimulation with Task-oriented exercises												
Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation	Gait training with transcranial direct current stimulation with conventional rehabilitation												
Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation	Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation												
Gait training with transcranial direct current stimulation with conventional rehabilitation	Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation												
Ankle foot orthosis with gait training	functional electrical stimulation with gait training												
Core Muscle Training with functional electrical stimulation	Core Muscle Training Alone												
Foot drop stimulator with treadmill training and Basic rehabilitation training	Foot drop stimulator training with Basic rehabilitation training												
Fast speed treadmill training with functional electrical stimulation	Self-Selected Speed Treadmill Training or Fast Speed Treadmill Training												
Modified Dynamic Ankle Foot Orthosis (including functional electrical stimulation) with Conventional physiotherapy	Conventional physiotherapy												
Gait training with functional electrical stimulation and Action observation	Gait training with functional electrical stimulation												

Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation	Overground gait training												
Gait Trainer GT II (Rehastim) with Functional electrical stimulation and Regular rehabilitation	Gait Trainer GT II (Rehastim) with Regular rehabilitation												
Electromechanical gait trainer with Functional electrical stimulation and Conventional physical therapy	Gait training with Conventional physical therapy												
Electromechanical gait trainer with Functional electrical stimulation and Conventional therapy	Overground gait training with Conventional therapy												
Bicephalic Transcranial direct-current stimulation with Footdrop stimulator and Treadmill gait training	Sham transcranial direct-current stimulation with Footdrop stimulator and treadmill gait training												
Functional electrical stimulation with Proprioceptive Neuromuscular Facilitation	Proprioceptive Neuromuscular Facilitation												
Proprioceptive neuromuscular facilitation trunk pattern with electromyography-triggered functional electrical stimulation	proprioceptive neuromuscular facilitation trunk pattern												
Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation)	Functional electric stimulation (functional electrical stimulation)												
M1 anodal transcranial direct current stimulation with functional electrical stimulation and Conventional care	20min/d functional electrical stimulation with Conventional care or 20min/d functional electrical stimulation and 20min/d conventional care, 5d/wk, for 2wks												
Rehabilitation with electromyography biofeedback	Conventional rehabilitation												
Botulinum toxin A (500U) with functional electrical stimulation	Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching												
Over-Ground Gait Training + BWS Treadmill Training + Functional electrical stimulation with intramuscular electrodes	Over-Ground Gait Training + BWS Treadmill Training												

Neuromuscular Electrical Stimulation (NMES) (36 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Cyclic neuromuscular electrical stimulation	Conventional Therapy or Neurodevelopmental Techniques												
Neuromuscular electrical stimulation Therapy	Conventional Therapy												
Electromyography-triggered neuromuscular electrical stimulation	Conventional Therapy												
Contralaterally Controlled neuromuscular electrical stimulation	Cyclic neuromuscular electrical stimulation or neuromuscular electrical stimulation												
Contralaterally controlled neuromuscular electrical stimulation with conventional therapy	neuromuscular electrical stimulation with conventional therapy												
Conventional rehabilitation with mirror therapy and neuromuscular electrical stimulation	Conventional rehabilitation with mirror therapy												
Neuromuscular electrical stimulation Therapy	Mirror Therapy												

Neuromuscular electrical stimulation with Exercise Therapy	Exercise Therapy												
Neuromuscular electrical stimulation with Passive Ankle Movement Training	neuromuscular electrical stimulation Alone												
Electromyography-triggered Pedaling training	Pedaling training												
Conventional rehabilitation with mirror therapy and neuromuscular electrical stimulation	conventional rehabilitation with Sham mirror therapy												
Neuromuscular electrical stimulation on tibialis anterior with ambulation training	neuromuscular electrical stimulation on medial gastrocnemius with ambulation training												
Interferential Current neuromuscular electrical stimulation with Air-pump Massage	Sham												
Passive Movement Training with cyclic neuromuscular electrical stimulation	Cyclic neuromuscular electrical stimulation												
Passive Movement Training with cyclic neuromuscular electrical stimulation	Passive Movement Training												
Cyclic neuromuscular electrical stimulation	Passive Movement Training												
Sensory threshold neuromuscular electrical stimulation with Conventional therapy	Conventional therapy												
Mirror Therapy with Cyclic neuromuscular electrical stimulation	Conventional Therapy												
Neuromuscular electrical stimulation with Walking Training	Conventional Walking Training with Ankle-Foot Orthosis												
Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles	Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles												
Neuromuscular electrical stimulation Stimulation	Sham Stimulation												
Neuromuscular electrical stimulation (Walkaide) with walking training and conventional therapy	Walking training with ankle-foot-orthosis and conventional therapy												
Mirror therapy with cyclical neuromuscular electrical stimulation and conventional physical therapy	Conventional therapy												
Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy	Conventional rehabilitation												
Electromyography-triggered neuromuscular electrical stimulation with tilt sensor functional electrical stimulation training (combined electrical stimulation) and conventional physiotherapy	Electromyography triggered neuromuscular electrical stimulation training (single electrical stimulation) with conventional physiotherapy												
Botox Injections (50U- 120U) with neuromuscular electrical stimulation of Antagonist and Injected Agonist Muscles	Botox Injections (50U- 120U) with neuromuscular electrical stimulation of Injected Agonist Muscles												
Proprioceptive neuromuscular facilitation trunk pattern with electromyography-triggered functional electrical stimulation	proprioceptive neuromuscular facilitation trunk pattern												
Cyclic neuromuscular electrical stimulation	Trunk/Core Training												
Trunk neuromuscular electrical stimulation with Core muscle training	Trunk neuromuscular electrical stimulation												

Dual-afferent sensory input (electromyography-triggered functional electrical stimulation with Action Observation)	Functional electric stimulation (functional electrical stimulation)												
Tele-supervising rehabilitation (physical therapy with electromyography-neuromuscular electrical stimulation)	Conventional Care												
Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation	rehabilitation												
Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation	Neuromuscular Electrical Stimulation with Early Rehabilitation												
Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)												
Neuromuscular Electrical Stimulation	Occupational Therapy												
Neuromuscular electrical stimulation (NMES)	Sham NMES												

Transcutaneous Electrical Nerve Stimulation (TENS) (33 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Transcutaneous electrical nerve stimulation Stimulation, Conventional Therapy or No Treatment	Sham Stimulation, Conventional Therapy or No Treatment												
Unilateral transcutaneous electrical nerve stimulation	Bilateral transcutaneous electrical nerve stimulation												
Balance Training with transcutaneous electrical nerve stimulation	Sham transcutaneous electrical nerve stimulation with Balance Training vs Conventional Care												
Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care	Weight-shifting training with Placebo transcutaneous electrical nerve stimulation and Conventional care												
Weight-shifting exercise with transcutaneous electrical nerve stimulation and Conventional care	Conventional care												
Transcutaneous electrical nerve stimulation with rehabilitation	Sham transcutaneous electrical nerve stimulation with rehabilitation												
Transcutaneous electrical nerve stimulation with exercise	Sham transcutaneous electrical nerve stimulation with exercise, transcutaneous electrical nerve stimulation only, or No Treatment												
Transcutaneous electrical nerve stimulation with Exercise	Sham transcutaneous electrical nerve stimulation with Exercise or transcutaneous electrical nerve stimulation												
Transcutaneous electrical nerve stimulation with Exercise	transcutaneous electrical nerve stimulation or Sham transcutaneous electrical nerve stimulation with Exercise												
Transcutaneous electrical nerve stimulation with Task-related Training	Task-related training												
Transcutaneous electrical nerve stimulation (60min) with Task- related training	transcutaneous electrical nerve stimulation (30min) with Task-related training												

Transcutaneous electrical nerve stimulation with Task-related training	transcutaneous electrical nerve stimulation												
Transcutaneous electrical nerve stimulation with Task-related training	Placebo transcutaneous electrical nerve stimulation with Task- related training												
Transcutaneous electrical nerve stimulation	Placebo transcutaneous electrical nerve stimulation with Task- related training												
Transcutaneous electrical nerve stimulation with Task-related training	transcutaneous electrical nerve stimulation or Placebo transcutaneous electrical nerve stimulation with Task- related training												
Electroacupuncture and Low Frequency transcutaneous electrical nerve stimulation	High and Low Frequency transcutaneous electrical nerve stimulation												
Transcutaneous electrical nerve stimulation with Heel-raise-lower training	Placebo transcutaneous electrical nerve stimulation with Heel-raise-lower training												
Transcutaneous electrical nerve stimulation with task-oriented balance training and conventional therapy	C: Sham transcutaneous electrical nerve stimulation with task- oriented balance training and conventional therapy												
Transcutaneous electrical nerve stimulation	No treatment												
Transcutaneous electrical nerve stimulation	No active treatment												
Transcutaneous electrical nerve stimulation with Taping and Exercise	transcutaneous electrical nerve stimulation with Exercise												
Instructed sensory training with transcutaneous electrical nerve stimulation	Uninstructed sensory training with transcutaneous electrical nerve stimulation												
Low-dose Botulinum toxin (100U) with transcutaneous electrical nerve stimulation	High-dose Botulinum toxin (400U) with Sham electrical stimulation												
Electroacupuncture	Low-intensity, high-frequency transcutaneous electrical nerve stimulation (2Hz) electrostimulation												
Transcutaneous electrical nerve stimulation with Task-related training	Sham transcutaneous electrical nerve stimulation with Task-related training												
Transcutaneous electrical nerve stimulation vs Conventional Therapy	neuromuscular electrical stimulation vs Conventional Therapy												
Transcutaneous Nerve Stimulation (transcutaneous electrical nerve stimulation) with Early Rehabilitation	Neuromuscular Electrical Stimulation with Early Rehabilitation												
Sit-to-stand training with transcutaneous electrical nerve stimulation and conventional therapy	Sit-to-stand training with sham transcutaneous electrical nerve stimulation and conventional therapy												
Therapeutic ultrasound with Home exercises & conventional therapy	transcutaneous electrical nerve stimulation with Home exercises & conventional therapy												
Therapeutic ultrasound with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy												
Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy												
Trunk Training with Balance Training and transcutaneous electrical nerve stimulation	Treadmill Training and Placebo transcutaneous electrical nerve stimulation												

Multi-sensorimotor training (Stabilize-T and Reha bar exercises with transcutaneous electrical nerve stimulation) and Conventional physical therapy	Treadmill training with placedo transcutaneous electrical nerve stimulation and conventional physical therapy												

Muscle Vibration (16 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Whole Body Vibration	Sham Stimulation, No Stimulation, or Conventional Care												
Local Muscle Vibration	Conventional Therapy or Sham Muscle Vibration												
Gastrocnemius vibration with conventional	Tibialis anterior vibration with conventional												
Vibrational and Heated Stone-Needle Therapy with Meridian Dredging Exercise	Meridian Dredging Exercise												
Whole Body Vibration	Musical Exercise Therapy												
Balance Training with Whole Body Vibration	Conventional Rehabilitation												
Whole Body Vibration with Treadmill Training	Treadmill Training												
Comparing Whole-Body Vibration Intensity	Sham with therapy												
High-frequency (26 Hz) Whole-body vibration training with therapy	Low-frequency (13 Hz) Whole-body vibration training with therapy												
High frequency (30Hz) whole body vibration	Low frequency (20Hz) whole body vibration												
Whole Body Vibration	Strength Training												
Vibrosphere (balance training with whole body vibration) and conventional geriatric rehabilitation	Conventional geriatric rehabilitation												
Matrix Rhythm Therapy	Bobath Therapy												
Task-Specific Training with Whole-Body Vibration Treatment (With an increase in frequency, sets, and time)	Task-Specific Training with Sham Vibration												
Vibration on sole of foot	Contact on sole of foot with No vibration												
Neuromuscular Electrical Stimulation	Occupational Therapy												

Additional Afferent and Peripheral Stimulation Methods (10 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Intermittent Pneumatic Compression	Conventional Therapy												
Sensory Training with Trunk Training	Trunk Training Alone												
Transcutaneous Auricular Vagus Nerve Stimulation with or without transcranial direct current stimulation	Conventional Therapy												
Tactile Sensory Stimulation	Conventional Care												
Afferent Electrical Stimulation with Mirror Therapy	Sham												
Laser Photo-biomodulation	Sham												

Instructed Sensory Training with transcutaneous electrical nerve stimulation	Uninstructed Sensory Training with transcutaneous electrical nerve stimulation												
Tactile stimulation and mobilization + task specific gait training	task specific gait training + unlimited textured insole wearing												
Sensory Training	Conventional Therapy												
NeuroDevelopmental rehabilitation + Center of pressure movement track in dynamic mode	Neurodevelopmental rehabilitation + Center of pressure movement track training in static mode												

Remote Ischemic Conditioning (1 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Remote Ischemic Conditioning	Sham or Conventional Therapy												

Thermal Stimulation and Cryotherapy (5 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Thermal Stimulation	Sham or No Stimulation												
Robot guided ankle proprioceptive training with Thermal tactile stimulation and Conventional therapy	Conventional Therapy												
Ankle Proprioceptive Training with Thermotherapy	Conventional Therapy												
Cryotherapy	Sham												
Cryotherapy with Physical Therapy with Ankle foot Orthosis	Physical Therapy with Ankle foot Orthosis												

Extracorporeal Shockwave Therapy and Therapeutic Ultrasound (12 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Extracorporeal Shockwave Therapy	Sham or Conventional Therapy												
Therapeutic Ultrasound	Sham or Conventional Therapy												
Radial Extracorpeal Shock Wave Therapy with Visual Feedback Balance Training	Sham with Visual Feedback Balance Training												
Focused Shockwave Therapy	Radial Shockwave Therapy												
Therapeutic ultrasound	Radial extracorporeal shock wave therapy (radial extracorporeal shockwave therapy)												
Double dose extracorporeal shockwave therapy	Single dose extracorpeal shockwave therapy												
Therapeutic ultrasound with Home exercises & conventional therapy	transcutaneous electrical nerve stimulation with Home exercises & conventional therapy												
Therapeutic ultrasound with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy												

Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy												
Extracorpeal shockwave therapy	extracorporeal shockwave therapy with Isokinetic strength training												
Extracorporeal Shock-wave Therapy on Muscle Belly (0.068 0.093 mJ/mm², 1,500 shots)	Sham Extracorporeal Shock-wave Therapy (sound only)												
Extracorporeal Shock-wave Therapy on Muscle Belly (0.068 0.093 mJ/mm², 1,500 shots)	Extracorporeal Shock-wave Therapy on Myotendinous Junction (0												

Repetitive Peripheral Magnetic Stimulation (2 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Repetitive Peripheral Magnetic Stimulation	Sham												
Repetitive Peripheral Magnetic Stimulation	neuromuscular electrical stimulation, Muscle Vibration, and Conventional therapy												

Repetitive Transcranial Magnetic Stimulation (rTMS) (21 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Low frequency (1Hz) repetitive transcranial magnetic stimulation	Sham Stimulation												
Low-frequency repetitive transcranial magnetic stimulation with Conventional rehab	Sham repetitive transcranial magnetic stimulation with Conventional rehab												
Primary motor area repetitive transcranial magnetic stimulation	Supplementary motor area repetitive transcranial magnetic stimulation												
High Frequency (>1Hz) repetitive transcranial magnetic stimulation	Sham Stimulation												
High Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation	Low Frequency repetitive transcranial magnetic stimulation or Sham repetitive transcranial magnetic stimulation												
High frequency repetitive transcranial magnetic stimulation (10Hz) with Conventional therapy	Low frequency repetitive transcranial magnetic stimulation (1Hz) with Conventional therapy												
Ipsilesional repetitive transcranial magnetic stimulation (3Hz) with Physical therapy	Contralesional repetitive transcranial magnetic stimulation (1Hz) with Physical therapy												
Combined High and Low Frequency repetitive transcranial magnetic stimulation	Therapy												
Low Frequency repetitive transcranial magnetic stimulation	transcranial direct current stimulation or Combined repetitive transcranial magnetic stimulation and transcranial direct current stimulation or Sham												

Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy												
High Frequency repetitive transcranial magnetic stimulation Combined with Treadmill Training	Treadmill Training												
High Frequency repetitive transcranial magnetic stimulation with Cathodal transcranial direct current stimulation	repetitive transcranial magnetic stimulation												
Repetitive transcranial magnetic stimulation Combined with Cycling Exercise	Cycling Exercise Alone												
Repetitive transcranial magnetic stimulation Combined with Virtual/Augmented Reality Gait Training	Virtual/Augmented Reality Gait Training Alone												
Repetitive transcranial magnetic stimulation Combined with Motor Relearning	Motor Relearning Alone												
Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Sham repetitive transcranial magnetic stimulation												
Ankle Strengthening	repetitive transcranial magnetic stimulation												
Ankle Strengthening with high frequency (10Hz) Repetitive Transcranial Magnetic Stimulation	Ankle Strengthening												
Mirror therapy with Repetitive transcranial magnetic stimulation	Mirror therapy with Sham stimulation												
Low Frequency (1Hz) repetitive transcranial magnetic stimulation	Conventional Therapy												
Low frequency (3Hz) repetitive transcranial magnetic stimulation with conventional care	High frequency (10Hz) repetitive transcranial magnetic stimulation with conventional care												

Theta Burst Stimulation (TBS) (5 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Intermittent Theta Burst Stimulation	Sham Stimulation												
Intermittent theta burst stimulation to M1 with Conventional physiotherapy	intermittent theta burst stimulation to contralateral cerebellar hemisphere with Conventional physiotherapy												
Cerebellar Intermittent Theta Burst Stimulation	Sham												
Intermittent theta burst stimulation unilateral cerebellar area (CB Single group)	intermittent theta burst stimulation Cerebellar primary motor cortex area (CB-M1 group) or intermittent theta burst stimulation Cerebellar Supplementary Motor Area (CB-SMA group)												
Peripheral Intermittent Theta Burst Stimulation	Sham												

Transcranial Direct Current Stimulation (tDCS) (45 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Comparison of transcranial direct current stimulation Stimulation Conditions	Sham transcranial direct current stimulation												
Bihemispheric transcranial direct current stimulation with Conventional physical therapy	Unihemispheric transcranial direct current stimulation with Conventional physical therapy												
Dual transcranial direct current stimulation with Conventional therapy	Anodal transcranial direct current stimulation with Conventional therapy												
Dual transcranial direct current stimulation with Conventional therapy	Cathodal transcranial direct current stimulation with Conventional therapy												
Transcranial direct current stimulation with Robot-assisted Gait Training	Sham transcranial direct current stimulation with Robot-assisted gait training												
Dual transcranial direct current stimulation with Task-oriented training	Sham transcranial direct current stimulation with Task-oriented training												
Transcranial direct current stimulation with Ankle Motor Tracking and High-intensity speed-based treadmill training	High-intensity speed-based treadmill training												
Transcranial direct current stimulation priming only (Transcranial Direct Current Stimulation with High-intensity speed-based treadmill training)	AMT priming only (Ankle motor tracking with Sham Transcranial Direct Current Stimulation, High-intensity speed-based treadmill training) or transcranial direct current stimulation & AMT priming (Transcranial Direct Current Stimulation, Ankle motor tracking and High-intensity speed-based treadmill training)												
Transcranial direct current stimulation with Body weight supported treadmill training	transcranial direct current stimulation with Body weight supported treadmill training												
Transcranial direct current stimulation Combined with High or Low Frequency repetitive transcranial magnetic stimulation	repetitive transcranial magnetic stimulation or Sham												
Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Cathodal transcranial direct current stimulation with repetitive transcranial magnetic stimulation (1Hz), conventional therapy or Anodal transcranial direct current stimulation, repetitive transcranial magnetic stimulation (1Hz) and conventional therapy												
Transcranial direct current stimulation with conventional therapy	Functional electrical stimulation with conventional therapy												
Transcranial direct current stimulation with Gait Training	Sham transcranial direct current stimulation with Gait Training												
Transcranial direct current stimulation with Conventional Therapy	Sham transcranial direct current stimulation with Conventional Therapy												
Transcranial direct current stimulation with Treadmill Training	Sham transcranial direct current stimulation with Treadmill Training												
Bilateral transcranial direct current stimulation and Treadmill	Cathodal transcranial direct current stimulation and Treadmill												
Transcranial direct current stimulation with Individualized Physiotherapy	Sham transcranial direct current stimulation with Individualized Physiotherapy												

Bihemisphere transcranial direct current stimulation with individual physio plan	Unihemisphere transcranial direct current stimulation with individual physio plan												
Transcranial direct current stimulation with Home-Based Exercise	Sham transcranial direct current stimulation with Home-Based Exercise												
Transcutaneous auricular vagus nerve stimulation with dual transcranial direct current stimulation	Neurodevelopmental Bobath supplemented with Occupational Therapy												
Repetitive transcranial magnetic stimulation (1Hz) with conventional therapy	Sham repetitive transcranial magnetic stimulation												
Dual-mode transcranial direct current stimulation (2mA) with repetitive transcranial magnetic stimulation (10Hz)	repetitive transcranial magnetic stimulation (10Hz)												
Anodal transcranial direct current stimulation (2mA)	Bilateral transcranial direct current stimulation (2mA) or Cathodal transcranial direct current stimulation (2mA)												
Bilateral transcranial direct current stimulation (2mA)	Cathodal transcranial direct current stimulation (2mA)												
Dual transcranial direct current stimulation	Anodal transcranial direct current stimulation or Cathodal transcranial direct current stimulation												
Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation and Cathodal transcutaneous spinal direct current stimulation (2												
Robot-assisted gait training (G-EO) with Anodal transcranial direct current stimulation (2mA) and sham transcutaneous spinal direct current stimulation	Robot-assisted gait training (G-EO) with sham transcranial direct current stimulation, Cathodal transcutaneous spinal direct current stimulation (2												
Anodal transcranial direct current stimulation with Robot- assisted gait training	Sham transcranial direct current stimulation with Robot- assisted gait training												
Cerebellar transcranial direct current stimulation with Split-belt treadmill training	Sham cerebellar transcranial direct current stimulation with Split-belt treadmill training												
Transcranial direct current stimulation with Task-related training	Task-related training												
Contralesionally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training	Ipsileisonally cathodal transcranial cerebellar direct current stimulation (2mA) with cathodal transcutaneous spinal direct current stimulation and Robot-assisted gait training												
Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation	Gait training with transcranial direct current stimulation with conventional rehabilitation												
Gait training with functional electrical stimulation with sham transcranial direct current stimulation and conventional rehabilitation	Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation												
Gait training with transcranial direct current stimulation with conventional rehabilitation	Gait training with transcranial direct current stimulation and functional electrical stimulation with conventional rehabilitation												
Transcranial direct current stimulation with Trunk Training	Sham transcranial direct current stimulation with Trunk Training												

Trunk-targeted,proprioceptive neuromuscular facilitation with Bihemispheric transcranial direct current stimulation and Conventional physiotherapy	Trunk-targeted,proprioceptive neuromuscular facilitation with sham transcranial direct current stimulation and Conventional physiotherapy												
Transcranial direct current stimulation with Videogame Training	Sham transcranial direct current stimulation with Videogame Training												
Xbox training during anodal transcranial direct current stimulation stimulation to cerebellum	Xbox training during nodal transcranial direct current stimulation stimulation to motor cortex												
Anodal Cerebellar transcranial direct current stimulation with Xbox Kinect games ; E2 Anodal M1 transcranial direct current stimulation and Xbox Kinect games	the other study arms												
Transcranial direct current stimulation with Foot Drop Stimulator and Treadmill Training	Sham transcranial direct current stimulation with Foot Drop Stimulator and Treadmill Training												
Cathodal cerebellar stimulation (tcDCS) + cathodal spinal	control												
Anodal transcranial direct current stimulation (2mA) with Conventional care	Cathodal transcranial direct current stimulation (2mA) with Conventional care												
Transcranial Direct Current Stimulation	Functional Electrical Stimulation												
Anodal transcranial direct current stimulation	Dual transcranial direct current stimulation												
Anodal transcranial direct current stimulation with Conventional care	Cathodal transcranial direct current stimulation with Conventional care												

Antidepressants (9 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Fluoxetine	Placebo												
Shu-Gan-Jie-Yu vs Placebo	Fluoxetine vs Placebo												
Escitalopram	Placebo												
Citalopram vs Placebo	Fluoxetine vs Placebo												
20mg/d Citalopram & Physiotherapy	20mg/day Fluoxetine & Physiotherapy												
Shu-Gan-Jie-Yu capsule, 720 mg	Placebo												
Fluoxetine vs Placebo	Maprotiline vs Placebo												
Fluoxetine (20mg/d)	Maprotiline (150mg/d)												
Citalopram	Placebo												

Secondary Prevention Medications (8 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Tirofiban	Placebo												
Olmesartan	Amlodipine												
Naftidrofuryl fumarate	Placebo												

Alteplase	Aspirin												
PF-3049423	Placebo												
Nimodipine	Placebo												
Rivaroxaban	Aspirin												
DLBS1033 (Lumbrokinase)	Conventional Therapy												

Edaravone (2 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Long-term Edaravone (30mg, 2x/d) 10-15 days with Conventional care	the other study arms												
Edaravone Injection	Conventional Treatment												

Stimulants (6 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Amphetamines	Placebo												
Amphetamine with Intensive Physiotherapy	Amphetamine with Conventional Physiotherapy												
Amphetamine vs Placebo	Levodopa vs Placebo												
Methylphenidate	Placebo												
Methylphenidate vs Placebo	Levodopa vs Placebo												
Methylphenidate (20mg/d) with conventional physiotherapy	Levodopa (125mg/d) with conventional physiotherapy or Methylphenidate, Levodopa and conventional physiotherapy												

Dopamine Agonists (7 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Levadopa or No Medication	Placebo or No Medication												
Levodopa with Stimulants	Placebo with conventional physiotherapy												
Methylphenidate (20mg/d) with conventional physiotherapy	Levadopa (125mg/d) with conventional physiotherapy or Methylphenidate, Levadopa and conventional physiotherapy												
Ropinirole	Placebo												
Amphetamine (10mg/d) with Levodopa (50mg/d)	Amphetamine placebo with Levodopa placebo												
Methylphenidate (20mg/d) with conventional physiotherapy	Placebo with conventional physiotherapy												
Methylphenidate (20mg/d) with conventional physiotherapy	Levodopa (125mg/d) with conventional physiotherapy or Methylphenidate, Levodopa and conventional physiotherapy												

Nerve Block Agents (5 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Tibial nerve block through thermocoagulation with ankle-foot orthosis	Thermocoagulation with Sham ankle-foot orthosis or Sham thermocoagulation, ankle-foot orthosis or Sham thermocoagulation and Sham ankle-foot orthosis												
50% Ethyl alcohol injection (5mL)	5% Phenol injection (5mL)												
Curare Medications	Homeopathic Medications												
Botulinum Toxin A (400 U)	Phenol												
Botulinum Toxin A (400 U)	Tibial nerve blockade (Phenol)												

Botulinum Toxin (38 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Botulinum Toxin A	Placebo												
Botulinum Toxin A with Ankle-foot Orthosis	Conventional rehabilitation												
Botulinum Toxin A with functional electrical stimulation	Botulinum toxin A injection												
Botulinum toxin A (100U) in mid belly of the gastrocnemius with placebo injected in distal of popliteal fossa	Botulinum toxin A (100U) at distal to the popliteal fossa with placebo injected in mid belly												
Dosage of Injection	Placebo												
Ultrasonography guided Botulinum toxin A (1000U)	Electrical stimulation guided Botulinum toxin A (1000U)												
Botulinum Toxin A	Conventional Therapy												
Botulinum Toxin A with Casting or Taping	Botulinum toxin A (75- 100U) with Sham taping and home exercises												
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with Taping and stretching and gait training												
Botulinum toxin A (100U) with Serial casting and stretching and gait training	Botulinum toxin A (100U) with stretching and gait training												
Botulinum toxin A (100U) with Taping and stretching and gait training	Botulinum toxin A (100U) with stretching and gait training												
Botulinum Toxin A with Electrical Stimulation	Botox Injections (50U- 120U) with neuromuscular electrical stimulation of Injected Agonist Muscles												
Botulinum Toxin A with transcutaneous electrical nerve stimulation	High-dose Botulinum toxin (400U) with Sham electrical stimulation												
Botulinum toxin (200U)	Neurotomy												
Location of Injection	Distal gastrocnemius Botulinum toxin A injection 200U												
Botulinum toxin A with Conventional Therapy (300U)	Botulinum toxin A with Conventional Therapy (100U)												
Botulinum toxin A (167U)	Botulinum toxin A (540U)												
Botulinum toxin A (322U)	Botulinum toxin A (540U)												

Botulinum Toxin A Injection with Home-based task-oriented rehabilitation and Usual physiotherapy	Botulinum Toxin A Injection												
Botox Combined with Robotics	Botox and Conventional Therapy												
Botulinum Toxin A with electromyography Biofeedback Treatment and Conventional Care	Botulinum Toxin A with Conventional Care												
Botox (200 units of BT- A) Early (140 Days Post Stroke)	Botox (200 units of BT- A) Middle (247 Days Post Stroke) or Botox (200 units of BT- A) Late (537 Days Post Stroke)												
Forward Treadmill Training with Botulinum Toxin	Backward Treadmill Training with Botulinum Toxin												
Backward treadmill training with botulinum toxin type A therapy	forward treadmill training with botulinum toxin type A therapy												
Botulinum toxin A (190-320U) with ankle-foot orthosis	Botulinum toxin A (190-320U)												
Botulinum toxin A (100U) injection into tibialis posterior with ankle-foot adhesive taping	electromyography-guided Botulinum toxin A (190-320U) injection into several calf muscles												
Botox Injections (50U-120U) with Electrical Stimulation of Antagonist and Injected Agonist Muscles	Botox Injections (50U-120U) with Electrical Stimulation of Injected Agonist Muscles												
Botulinum toxin A (500U) with functional electrical stimulation	Botulinum toxin A (500U) with Taping or Botulinum toxin A (500U) and Stretching												
OnabotulinumtoxinA (200U)	OnabotulinumtoxinA (300U)												
Botulinum Toxin A (50-100U) + Isokinetic training	Botulinum Toxin A (50-100U)												
Therapeutic ultrasound with Home exercises & conventional therapy	transcutaneous electrical nerve stimulation with Home exercises & conventional therapy												
Therapeutic ultrasound with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy												
Transcutaneous electrical nerve stimulation with Home exercises & conventional therapy	Botulinum toxin A (200U) with Home exercises & conventional therapy												
Botulinum toxin A (200U) by ultrasonography	Botulinum toxin A (200U) by electrical stimulation												
Botulinum toxin A (200U) by ultrasonography	Botulinum toxin A (200U) by palpation												
Botulinum toxin A (200U) by electrical stimulation	Botulinum toxin A (200U) by palpation												
Botulinum Toxin A (400 U)	Phenol												
Botulinum Toxin A (400 U)	Tibial nerve blockade (Phenol)												

Antispastic Drugs (6 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Intrathecal Baclofen	Placebo												
Tolperisone	Placebo												
Magnesium Sulphate Iontophoresis	Stretching												
Dantrolene	Placebo												
Tizanidine	Placebo												
Tizanidine (8mg, titrated up to max 20mg)	Baclofen (20mg, titrated up to max 50mg)												

Cerebrolysin (1 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Taping	no taping, sham taping, or conventional therapy												

4-Aminopyridine (1 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Dalfampridine	Placebo												

Biologics and Targeted Molecular Therapies (6 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Ganglioside GM1	Placebo												
Mesenchymal Stem Cell Injection	Placebo or Conventional Therapy												
Neuronal Cell	Conventional Therapy												
Cutamesine	Placebo												
Granulocyte-colony Stimulating Factor	Placebo												
5million implanted human neuronal cells with Conventional rehabilitation	10million implanted human neuronal cells with Conventional rehabilitation												

Anabolic Steroids (1 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Taping	no taping, sham taping, or conventional therapy												

Supplements and Vitamins (8 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Dietary Protein Supplement with Cycle Ergometer	Carbohydrate Supplement with Cycle Ergometer												
Vitamin and comprehensive Dietary Supplementation	regular meds (meds required for their clinical condition) with intensive rehabilitation treatment												
Primary motor area repetitive transcranial magnetic stimulation	Sham repetitive transcranial magnetic stimulation												
Primary motor area repetitive transcranial magnetic stimulation	Supplementary motor area repetitive transcranial magnetic stimulation												
Leucine-enriched Amino Acid Supplementation	Resistance training exercise program												

Soymilk Supplementation	Placebo												
Intermittent theta burst stimulation unilateral cerebellar area (CB Single group)	intermittent theta burst stimulation Cerebellar primary motor cortex area (CB-M1 group) or intermittent theta burst stimulation Cerebellar Supplementary Motor Area (CB-SMA group)												
DLBS1033 supplement (Lumbrokinase) with therapy	therapy												

Acupuncture and Massage (34 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio - ception	Stroke Severity	QoL
Acupuncture Therapy	Conventional Therapy												
Acupuncture	Physiotherapy or Acupuncture with PhysiotherapyNI												
Contra-lateral Needling (acupuncture on unaffected limbs)	Traditional acupuncture												
Acupuncture	Sham												
Channel Palpation Guided Acupuncture	Traditional Acupuncture												
Scalp Acupuncture and Robot Assisted Training	Basic Treatment												
Interactive Dynamic Scalp Acupuncture with lower-limb robot training (SA & LLRT simultaneously) and Basic Treatment	Scalp Acupuncture with lower-limb robot training (LLRT, SA separately) and Basic Treatment												
Scalp Acupuncture	Conventional Therapy or Other Modalities												
Auricular Intradermal Acupuncture	Conventional Therapy												
Acupuncture with Manipulation	Acupuncture												
Multifaceted Alternative Medicine Approaches	Meridian Dredging Exercise												
Neuronavigation-assisted aspiration with electroacupuncture	Neuronavigation-assisted aspiration												
Neuronavigation-assisted aspiration with electroacupuncture	Electroacupuncture												
Neuronavigation-assisted aspiration	Electroacupuncture												
Massage and other integrated rehabilitation techniques	Health education program												
Meridian Acupuncture	no Acupuncture												
Electroacupuncture with Conventional therapy	Conventional Therapy												
Electroacupuncture, usual care	Usual care												
Electroacupuncture with Conventional medication	Conventional medication												
Electrical Acupuncture with Conventional Therapy	Conventional therapy												
Dry Needling with Conventional Rehabilitation	Conventional Rehabilitation Alone												
Acupuncture with Robot-Assisted Gait Training	Acupuncture Alone												
Joint mobilization with acupuncture	Conventional rehab												
Joint mobilization with acupuncture	Joint mobilization												

Virtual reality-assisted gait adaptation training with acupuncture and conventional physical therapy	Overground gait adaptation training with acupuncture and conventional physical therapy												
One session daily high intensity Videogame exercises with medical massage	physical therapy with medical massage or 60min/d care and 20min/d massage												
Interferential current therapy (ICT) stimulation of gastrocnemius with air-pump massage and rehabilitation	Placebo-ICT with air-pump massage and rehabilitation												
Electroacupuncture	Low-intensity, high- frequency electrostimulation (80Hz)												
Electroacupuncture	Low-intensity, high-frequency transcutaneous electrical nerve stimulation (2Hz) electrostimulation												
Unani Medicine (Herbal and Massage)	Western Medicine (Piracetam 800mg)												
Acupuncture Treatment	No Treatment												
Whole-body vibration with conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)	Conventional rehab (physiotherapy, neuromuscular electrical stimulation, intermittent pneumatic compression, Bobath treatment, cardiorespiratory training, acupuncture treatment, occupational therapy)												
Eye Acupuncture	Body Acupuncture												
Electroacupuncture	Sham transcutaneous electrical nerve stimulation												

Electroacupuncture and Transcutaneous Electrical Acupoint Stimulation (8 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
Electroacupuncture Therapy	Conventional Therapy												
Neuronavigation-assisted aspiration with electroacupuncture	Conservative therapy												
Neuronavigation-assisted aspiration with electroacupuncture	Neuronavigation-assisted aspiration												
Neuronavigation-assisted aspiration with electroacupuncture	Electroacupuncture												
Neuronavigation-assisted aspiration	Electroacupuncture												
Electroacupuncture or transcutaneous electrical acupoint stimulation	Sham												
Electroacupuncture and Low Frequency transcutaneous electrical nerve stimulation	High and Low Frequency transcutaneous electrical nerve stimulation												
Electroacupuncture	Low-intensity, high- frequency electrostimulation (80Hz)												

Traditional Herbal Medicines (6 conclusions)

Intervention	Compared to	Motor Funct.	Funct. Ambul.	Funct. Mobility	Balance	Gait	ADLs	ROM	Muscle Strength	Spasticity	Proprio-ception	Stroke Severity	QoL
NeuroAid	Placebo												
Other Herbal Medications	Placebo or No Medication												
Qizhitongluo (500mg capsules) taken at breakfast and dinner with Placebo taken after lunch	Naoxintong (400mg capsules) taken after each meal												

Other Herbal Medications	Conventional Therapy												
Other Herbal Medications	Fluoxetine vs Placebo												
Chinese Traditional therapy (Bath in Chinese herbal medicine with Acupuncture with massage) and Conventional care	Conventional care
